UNIVERSAL DICTIONARY

OF

ARTS and SCIENCES.

D

D, The fourth letter in the alphabet, and the third conſonant.

The letter D is the fourth in the Hebrew, Chaldee, Samaritan, Syriac, Greek, and Latin alphabets; in the five firſt of which languages it has the ſame name, though ſomewhat differently ſpoken, *e. gr.* in Hebrew, Samaritan, and Chaldee, *Daleth;* in Syriac, *Dolath;* and in Greek, *Delta.*

The Arabians have three D's in their language, the firſt called *Dal*, which is the eighth of the twenty-eight letters; the ſecond, called *Dhſal*, is only diſtinguiſhed from the former by having a point added over it; though its ſound is much the ſame with that of the Z: the third, which is their ſeventeenth letter, is called *Da*, and pronounced like our D, though in form it reſembles the Arabic *Ta*, the difference being a point added at the top. The form of our D is the ſame with that of the Latins; as appears from all the ancient medals and inſcriptions. And the Latin D is no other than the Greek Δ, rounded a little, by making it quicker, and at two ſtrokes. The Δ of the Greeks, again, is borrowed from the ancient character of the Hebrew *Daleth;* which form it ſtill retains on the Samaritan coins, as is ſhewn by the Jeſuit Souciet, in his Diſſertation on the Samaritan Medals. All the alteration the Greeks have made in it, is the making it ſtoop a little, and taking away a little line. Nor would it be difficult to ſhew, that the Syriac *Dolath*, and the Arabic *Dal*, are both borrowed from the ancient Hebrew, as well as the ד *Daleth* of the modern, or ChaldeeHebrew.

Some indeed will have it, that the Greek Δ, *Delta*, is borrowed from the Egyptians, who made their D of three ſtars diſpoſed in a triangle; which was a hieroglyphic that among them denoted God, the ſovereign Being, as if they had ſome notion of a Trinity: but this ſurmiſe is weakly ſupported.

Grammarians generally rank D among the lingual letters, as ſuppoſing the tongue to have the principal ſhare in the pronunciation thereof; though the abbot de Dangeau ſeems to have reaſon in making it a palatal letter. It has one uniform ſound, nearly approaching to that of T, but formed by a ſtronger appulſe of the tongue to the upper part of the mouth.

D is alſo a numeral letter ſignifying *five hundred*, which ariſes hence, that in the Gothic characters the D is half the M, or CIↃ, which ſignifies a thouſand. Hence the verſe:

"Litera D velut A Quingentos ſignificabit."

A daſh added at the top of the $\overline{D}$, denotes it to ſtand for *five thouſand.*

D uſed in abbreviation has various ſignifications; thus, D ſtands for doctor, and M.D. doctor of medicine, D.T. doctor of theology, D.D. doctor of divinity, or *dono dedit;* D.D.D. is uſed for *dat, dicat, dedicat;* and D.D.D.D. for *dignum deo donum dedit.*

Among Roman writers, D ſtands for *divus, decimus, devotus, diebus*, and *diutius.*

D.M. in the Roman epitaphs ſignifies *diis manibus*, but on other occaſions *deo magno*, or *diis magnis;* D.N. denoted *dominus noſter*, a title given by the Romans to their emperors.

D, on the French coins, is the mark of the city of Lyons. D, in the chemical alphabet, ſignifies vitriol.

D, in *Engliſh Muſic*, is the initial of *D-ſol-re*, the 5th above gammut, in the ſcale of Guido. It occupies the 3d line in the baſe, and the 4th in the treble. In all tenor clefs it is in the ſpace immediately above the line on which the clef is placed. In French muſic, D has the ſame ſignification as P in the Italian; that is to ſay, *doux, ſoft.* The Italians ſometimes uſe it for *dolce*, which is not only oppoſed to *forte, loud*, but to rough and coarſe, and in Italian and Spaniſh muſic for keyed-inſtruments, it is uſed for *deſtra, the right-hand.* D, in German muſic, implies diſcant, or treble, in thorough baſe. In French muſic, it likewiſe

Strahan and Preſton,
New Street Square, London.

ſtands for *deſſus*, or *the treble part; d. m. dextra manu*, with the right-hand, is implied in leſſon-playing; and D. C. implies *Da Capo;* which ſee.

DA, is an Italian prepoſition, which implies *for:* as *da* cappella, for the chapel; ſonate *da* camera, chamber-ſonatas; ſonate *da* chieſa, ſonatas for the church. *Da* capo, repeat the firſt part from the beginning; *da* ſuonare, to be played in a ſong where the initial and incidental ſymphonies, or ritornelli, are interted in the ſame line as the voice part.

DAÆ, in *Ancient Geography*. See DAHÆ.

DAALDER, in *Commerce*. See DOLLAR and COIN.

DAALHAUSEN, in *Geography*, a town of Germany, in the circle of Weſtphalia, and biſhopric of Paderborn; 9 miles N.N.E. of Warburg.

DAB, in *Ichthyology*, a name given by the Engliſh to a ſmall fiſh of the pleuronectes kind, called by authors the *paſſer aſper* and *limanda*. See PLEURONECTES *limanda*.

DABAIBA, in *Mythology*, an idol of the inhabitants of Panama. This goddeſs, having been a female of diſtinguiſhed virtue, was deified after her death, and called by her votaries "the mother of God." To her anger they aſcribe thunder and lightning. In honour of her they burnt ſlaves as ſacrifices; and they worſhip her by faſting three or four days together, and by trivial acts of devotion, ſuch as ſighs, groans, extacies, and the like.

DABARITA, or DARABITA, in *Ancient Geography*, a village of Paleſtine, according to Joſephus, ſituated at the extremity of Galilee and Samaria.

DABASÆ, a people of India, on the other ſide of the Ganges.

DABASCHET, DABBASCHET, or *Dabbaſeth*, the frontier town of the tribe of Zabulon, in Paleſtine.

DABBER, in *Agriculture*, a term applied in ſome diſtricts to the tool uſed in dibbling, or ſetting different ſorts of crops, as thoſe of wheat, potatoes, and others. It is more frequently called a dibble or ſetting ſtick. See DIBBLE.

DABBERETH, in *Ancient Geography*, a town of Judæa, in the diviſion of the tribe of Iſſachar, according to the book of Joſhua; allotted to the Levites of the family of Gerſhon; and probably that called by Jerome *Dabira*, which he places towards mount Thabor, in the canton of Diocæſarea.

DABBING, in *Agriculture*, is a word ſometimes uſed to ſignify the operation of dibbling. See DIBBLING.

DABBUDA, in *Muſic*, a kind of Turkiſh dulcimer.

DAB-CHICK, in *Rural Economy*, a term which is ſometimes made uſe of to ſignify a chick which has been juſt hatched.

DABER, in *Geography*, formerly called *Dober*, a ſmall town of Pruſſia, in Pomerania, in the ancient duchy of Caſſuben, or Caſſubia.

DABER, or *Debir*, called *Kirjath-Sepher*, a town of Paleſtine, in the tribe of Judah, not far from Hebron. It was given to the Levites; after Joſhua had taken it and put its king to death.

DABHAUSEN, a ſmall town of Germany, in the circle of the Upper Rhine, with ſome thriving manufactures which were eſtabliſhed after the revocation of the edict of Nantes by induſtrious French Proteſtant refugees. It belongs to the counts of Solms, who at preſent hold their fiefs under the ſupremacy of the king of Weſtphalia.

DABIA, in *Ancient Geography*, a town of Africa, in Mauritania Tingitania, near mount Cirna.

DABIA, or *Dabai*, in *Geography*, a town of Egypt; 21 miles S. of Cairo.

DABIS, in *Mythology*, a deity of Japan, in repreſentation of which a large brazen Coloſſus, or image, is placed on the road from Oſacia to Sorungo. To this deity is offered annually a ſpotleſs virgin, who, being inſtructed to aſk the god ſome particular queſtions, receives an anſwer from a bonze, or prieſt, encloſed within the hollow of this idol.

DABLIS, in *Ancient Geography*, a town of Aſia Minor, in Bithynia; 24 miles from Cœnos Gallicanos, according to the Itinerary of Antonine.

DABO. See DACHSPERG.

DABRA-SHIN, in *Geography*, a town of Egypt; 12 miles S. of Cairo.

DABUH, in *Zoology*, a name given by the Arabs to the hyæna.

DABUL, in *Geography*, a town of India, on the coaſt of Concan, taken and ſacked by the Portugueſe, under the conduct of Almeyda, in 1509; but re-taken by the natives. The principal articles of its commerce are pepper and ſalt; 75 miles S. of Bombay. N. lat. 17° 52′. E. long. 72° 53′.

DA CAPO, Ital. muſical terms, implying, after an air or movement ſeems finiſhed, a return to the firſt part or ſtrain, which is to be repeated from the beginning, to the corona, 𝄐, or final mark; in the early periods of the opera, and of cantatas, when recitatives for the dialogue and narrative parts of a poem began to be terminated by ſhort airs, which often ſerved for ſeveral different ſtanzas, like thoſe of modern ballads. Before the terms da capo were in uſe, the air was written over again, as often as it was wanted, ſometimes in exactly the ſame notes, but more frequently, with little changes and embelliſhments, to the ſame baſe, and to different ſtanzas.

In the opera of Orontea, by Ceſti, performed at Venice, 1666, there are frequent returns to particular portions of the airs, more, indeed, in the manner of a refrein, or burden, than da capo, or rondo; but in the opera of Enea, performed at Genoa, 1676; in that of Aurora, ſet by Zanetti, and performed in the ſame city, 1678, there is a conſtant da capo, or return to the firſt part of each ſong. The practice ſeems to have begun about the year 1660. And in 1661, we find it ſometimes uſed in the opera of Clearco, ſet by Tenaglia, and performed at Rome. In the motets, *à voce ſola*, di Monferrato, printed 1673, da capos occur; about which time they became frequent; and before 1680, they appear to have been in conſtant uſe.

Among new muſical technica in the Arioſe Cantate of Sebaſtian Enno, publiſhed at Venice, 1655, we find da capo ſe piace, if you pleaſe. But the firſt intereſting air in a ſerious opera, that was performed in England, without a da capo, we believe, was, Se cerca ſe dice, in 1742, as ſet with ſuch dramatic propriety and effect by Pergoleſi, and ſung by Monticelli. The next was Rende mi il figlio mio, ſung by the Mattei in Cocchi's Ciro riconoſciuto, 1759. But it was in the operas of J. Chr. Bach, that da capos firſt totally diſappeared, and which, about this time, began to be generally diſcontinued: the ſecond part being incorporated with the firſt, to which, after modulating into the 5th of the key, the ſinger generally returns.

DACCA, in *Geography*, a town of Hindooſtan, ſituated in the eaſtern quarter of Bengal, and beyond the principal ſtream of the Ganges, though a very conſiderable branch of the ſame river runs through it. It is very favourably ſtationed for an inland emporium of trade, as the Dacca river communicates directly and not circuitouſly with all the other inland navigations. Dacca ſucceeded Sonergorg, as the provincial capital of this quarter; and it is the third city of Bengal, with reſpect to extent and population. It has a vaſt trade in muſlins, which are among the moſt delicate that are ſought after in Europe; and the cotton is produced within the province. Within the laſt century Dacca

was

was the capital of Bengal. It has ſtill the remains of a ſtrong fortreſs; and within a few years it had in its vicinity a cannon of extraordinary weight and dimenſions, which has ſince, together with the bank on which it reſted, fallen into the river. Major Rennell has given the dimenſions of this curious piece of artillery from his own meaſurement. His account of it is as follows; "It was made of hammered iron; it being an immenſe tube formed of 14 bars, with rings of 2 or 3 inches wide driven over them, and hammered down into a ſmooth ſurface; ſo that its appearance was equal to that of the beſt executed piece of braſs ordnance; although its proportions were faulty.

Whole length -	22 feet	10½ inches.
Diameter at the breech	3	3
——————4 feet from the muzzle	2	10
——————of the muzzle -	2	2½
——————of the bore -	1	3⅕

The gun contained 234,413 cubic inches of wrought iron; and conſequently weighed 64,814 pounds avoirdupoiſe, or [illegible]t the weight of eleven 32 pounders. Weight of an iron ſhot for the gun 465 pounds.

Dacca is ſituated about 100 miles above the mouth of the Ganges, and 180 by the road from Calcutta. The country round it lying low, and being always covered with verdure during the dry months, it is not ſubject to ſuch violent heats as Moorſhedabad, Patna, and other places. Its ſituation is 601 miles S. E. from Benares, 790 in the ſame direction from Lucknow, 120 E.S.E. from Moorſhedabad, and 177 N. E. from Calcutta. N. lat. 23° 43'. E. long. 90° 30'.

DACE, in *Ichthyology*, the Engliſh name for the fiſh, called by authors the *leuciſcus*. See CYPRINUS *leuciſcus*.

The dace is very common in our rivers, and is a remarkably lively fiſh. They ſpawn in February, and the males at that time are ſpotted and ſcabby, as in the rudd, &c. and are in higheſt ſeaſon for the table in April and May; but they are never a very well-taſted fiſh, or much eſteemed.

This fiſh gives the expert angler great diverſion. The dace will bite at any fly; but he is more than ordinarily fond of the ſtone-caddis, or May-fly, which is plentiful in the latter end of April, and the whole month of May. In warm weather this fiſh very ſeldom refuſes a fly at the top of the water; but at other times he muſt have the bait ſunk to within about three inches of the bottom. The winter fiſhing for dace requires a very different bait: this is a white maggot with a reddiſh head, which is the produce of the eggs of the beetle, and is turned up with the plough in great abundance. A parcel of theſe put in any veſſel, with the earth they were taken in, will keep many months, and ſupply an excellent bait.

Small dace may be put into a glaſs jar with freſh water, and there preſerved alive for a long time, if the water be properly changed. They have been obſerved to eat nothing but the animalcula in the water. They will grow very tame by degrees. Phil. Tranſ. N° 487. p. 23. ſeq.

DACHARENI, in *Ancient Geography*, a people of Arabia Felix. Ptolemy.

DACHAU, in *Geography*, a town of Bavaria, ſeated on an eminence on the river Ammer, in the diſtrict of Munich in Upper Bavaria, remarkable for an ancient caſtle. There is a communication between this place and Schleiſheim, a country palace of the kings of Bavaria, by means of a canal.

DACHETZ, or DACZICE, a ſmall town of Auſtria, in the margraviate of Moravia, in the diſtrict of Iglau, on the river Teya, with a convent of Franciſcan friars.

DACHINABADES, in *Ancient Geography*, a very populous country of India, S. of Barygaza, according to Arrian, in the Periplus of the Erythrean ſea.

DACHSBACH, in *Geography*, a town of Germany, in the circle of Franconia, and principality of Culmbach; 22 miles S. of Bamberg.

DACHSPERG, DAGSBOURG, or *Dabo*, a ſmall town of France, in the department of the Lower Rhine, in the diſtrict of Saverne, ſituated among the mountains called the Voſges, near the ſource of the river Sarre; 9 miles S. of Saverne.

DACHSTEIN, a ſmall town of France, in the department of the Lower Rhine, in the diſtrict of Straſbourg; 3 miles N. E. of Molſheim.

DACHSTUL, a town of Germany, in the circle of the Upper Rhine, and principal place of a lordſhip, which gives the poſſeſſor a ſeat and vote at the diets of the circle, but not of the empire; 22 miles S. E. of Treves.

DACI, in *Ancient Geography*, the people of Dacia, who inhabited the country N. of the Danube, from the plains occupied by the Sarmatian Jazyges, to the mouths of this river and the coaſt of the Euxine ſea. They had the ſame language with the Getæ. Strabo ſays, that they inhabited the upper part of this country, as it reſpects the courſe of the river, from the territory of the Suevi to that of the Tyrigetæ; and he aſſigns to the Getæ the lower part. Pliny, Steph. Byz., and Dion Caſſius ſay, that theſe people were called Getæ by the Greeks, and Dacians by the Romans. Herodotus calls them Scythians, and he gives them the epithet of immortals, becauſe they thought that, after death, they went to Zamolxis, who was a diſciple of Pythagoras. He had left them ſome inſtructions, which laid the foundation of their religion. They were a brave people. Alexander made war againſt them and burnt their city. The ſucceſſors of this prince attempted to ſubdue them, but one of their chiefs, having taken Lyſimachus, convinced them that they had done wrong in attacking a people as poor as they were brave. However, after the death of their king Berebiſtus, they quarrelled among themſelves, and unable to collect more then 20,000 men againſt Auguſtus, he vanquiſhed them without difficulty. They afterwards cauſed ſome diſturbance under Domitian; but Trajan effectually ſubdued them, and reduced their country into the ſtate of a Roman province. Florus ſays, that the Dacians croſſed the Danube, and advanced as far as Thrace, Macedonia, and Illyrium. Suetonius relates that Cæſar deſigned to reſtrain their progreſs; but this deſign was accompliſhed by Auguſtus. The emperor Aurelian, according to Vopiſcus, deſpairing of preſerving Dacia on the other ſide of the Danube, formed a new province of Dacia between the two territories denominated Mœſia.

It appears, however, that the Dacians inhabited the whole extent of country that lies between the Pruth, the Danube, the Tibiſcus, and the Carpathian mountains; and this was called "Dacia vera," or the province of Trajan. Under the reign of Trajan, Decebalus, king of the Dacians, revolted: upon which their prince, A.D. 106, carried his arms into Dacia, twice defeated theſe people, and formed their country into a Roman province, which was for a long time diſtinguiſhed by the name of "Provincia Trajani." See DACIA.

DACIA, the ancient name of two countries of Europe; the one on this ſide of the Danube called "Dacia Aureliani;" the other, called "Dacia Trajani," on the other ſide of the river. The latter comprehended Tranſylvania, Moldavia, Wallachia, and the bannat of Temeſwar, or

that country of Europe between the Danube and the Carpathian mountains, which, after an obſtinate ſtruggle of five years, was ſubdued by the Romans, annexed to the Roman empire in the reign of Trajan and joined to Mœſia, or modern Bulgaria, by an admirable bridge, the ruins of which are ſtill ſeen near Tſchernetz.

The river Tyras, Danaſter, or Nieſter, which runs from the north-weſt to the ſouth-eaſt, ſerved with the Alpes Baſtarnicæ, or Carpathian mountains, to form the boundary of this province to the north and north-eaſt. On the eaſt was the Euxine ſea, and on the weſt it was defended by an intrenchment. According to M. D'Anville, it was about 13 hundred miles in circumference. In the centre of the country was mount "Concajou," which was deemed ſacred by the Getæ. The principal rivers were the Danube, the Tibiſcus, Ternes, or Teyſs, the Aluta, the Ordeſſus, the Ararus, the Porata or Pretus, ſuppoſed to be the Hieraſſus of Ptolemy, and the Tyras or Danaſter. The chief towns of Dacia were, towards the north-weſt, Napoca, Prætoria Auguſta, Apulum, Tibiſcus, and Zarmigethuſa, called Ulpia Trajana; along the Danube from weſt to eaſt, Lederata oppoſite to Vominacium, which belonged to Mœſia, and Ternes, near the bridge of Trajan. The ancient hiſtorians ſcarcely make mention of the country, known under the name of Dacia, before the time when Darius carried his arms againſt the Daci in the year 508, B. C. After having traverſed the Thracian Boſphorus, he was in danger of loſing his whole army in the country of the Getæ, between the Iſter and the Aluta. Lyſimachus, to whom Thrace was allotted in the general diſtribution after the death of Alexander, made an unſucceſsful attack upon the Dacians, and was taken priſoner. In the times of Cæſar and Auguſtus, they took up arms againſt the Romans. However, Auguſtus and his firſt ſucceſſors reſtrained, both the Daci and Getæ, within the country on the other ſide of the Danube. Nevertheleſs, when the river was frozen and became paſſable, they made occaſional incurſions into the territory of the empire for the ſake of pillage. Auguſtus, in order to keep them within their own boundaries, entered into ſeveral treaties with them, the general character of which was moderation. Under the ſucceeding emperors the Dacians frequently recurred to arms; and under Domitian, Decebalus, their king, entered Mœſia and defeated Oppius Sabinus; but this emperor concluded with them a diſgraceful peace, and entered Rome in triumph.

Trajan obtained a degreee of ſucceſs, correſponding to his valour and military virtues; and advancing into the country humbled Decebalus and conſtrained him to ſue for peace, which the emperor granted him, though he proved treacherous, and attempted by his emiſſaries, to aſſaſſinate Trajan. The Roman forces afterwards penetrated into the country, and Decebalus, deſpairing of being able to reſiſt them, put an end to his own life. Trajan, as we have already ſaid, reduced Dacia into a Roman province and conſtructed a bridge over the Danube. Zarmigethuſa, the capital, aſſumed the name of the conqueror, and was from this time called Ulpia Trajana. Under the reigns of Adrian and Antonine the Dacians remained quiet; but neither they nor the emperors in ſubſequent periods adhered to the terms of the treaties and conventions that had been eſtabliſhed between them: at a ſubſequent period the Goths, among other inhabitants of the northern regions, invaded the Roman provinces; and they were particularly allured by the rich harveſts which covered the fields of Dacia. This new and unſettled province was neither ſtrong enough to reſiſt, nor rich enough to ſatiate the rapaciouſneſs of the barbarians. As long as the remote banks of the Nieſter were conſidered as the boundary of the Roman power, the fortifications of the Lower Danube were more careleſsly guarded, and the inhabitants of Mœſia lived in ſupine ſecurity, fondly conceiving themſelves at an inacceſſible diſtance from any barbarian invaders. The irruptions of the Goths, however, under the reign of Philip, fatally convinced them of their miſtake. Cniva, the king, or leader of that fierce nation, traverſed with contempt the province of Dacia, and paſſed both the Nieſter and the Danube without encountering any oppoſition capable of retarding his progreſs. At length the emperor Aurelian terminated the Gothic war, which had for 20 years occaſioned great calamities both to the Goths and the Romans, by a laſting and beneficial treaty. As a conſequence of this treaty, the emperor, in the year 274, relinquiſhed the ſovereignty of theſe Trans-Danubian provinces, and withdrew the Roman troops and coloniſts to the Cis-Danubian provinces of ancient Mœſia and Illyricum, or modern Bulgaria, Servia, and Boſnia, which were called Hither Dacia. Such of the Roman coloniſts as choſe to remain beyond the Danube were incorporated with the Goths, and ſerved as a medium of intercourſe between the Romans on the ſouth ſide of the Danube and the new ſettlers. The policy of Aurelian was juſtified by the event. The extenſive province of ancient Dacia, or Ulterior Dacia, which the Romans had been unable to defend, oppoſed, after it was become independent, a firm barrier againſt the incurſions of the ſavages of the north, until the declining ſtate of the Roman empire induced the inhabitants, after they had admitted ſucceſſive hordes of barbarians into their country, to iſſue out occaſionally from their woody retreats. They croſſed the Danube in their light boats, and marked their inroads into the Roman provinces with blood and ruin, even to the ſuburbs of Conſtantinople.

The treaty of peace which Attila, king of the Huns, dictated to Theodoſius and the eaſtern empire, A. D. 446, gave him the ſovereignty of ancient Dacia; and he ſtipulated, that, for the convenience of his Dacian ſubjects, a ſafe and plentiful market ſhould be eſtabliſhed on the ſouthern bank of the Danube.

After the death of Attila, and the extinction of his empire, Dacia became the ſeat of a new but tranſitory power, under Ardaric, king of the Gepidæ.

The countries of which ancient Dacia was compoſed were afterwards governed by petty princes, under the protection of the kings of Hungary. Theſe princes, having formed alliances with the kings of Poland, aſſumed independency, but were at laſt forced to ſurrender their countries as fiefs to Auſtria and the Ottoman Porte. Temeſwar and Tranſylvania are now conſidered as parts of the Auſtrian dominions; and Moldavia and Wallachia are tributary to the Ottoman Porte, but are at preſent invaded by the Ruſſians, and likely to be ſevered from the Turkiſh empire. See MOLDAVIA, WALLACHIA, TEMESWAR, TRANSYLVANIA.

DACIER, ANDREW, in *Biography*, was born at Caſtres in 1651; here alſo he received the early parts of his education, and would probably have completed his ſtudies in the ſame college, had not the management of it fallen entirely into the hands of the Jeſuits, a circumſtance that induced him to remove to Saumur, where he received inſtructions from Tannegui le Fevre, a man of great celebrity, whoſe daughter Dacier afterwards married. Within two years of their marriage, they both renounced the Proteſtant religion and conformed to the Roman Catholic faith. Dacier was firſt publicly known as an editor of ſeveral of the Greek and Roman claſſics, in which he was aſſiſted by his learned wife.

wife. He tranſlated the works of Horace into French proſe; the meditations of Marcus Antoninus; the Poetics of Ariſtotle; ſome of the Tragedies of Sophocles; the Manual of Epictetus, and the lives of Plutarch. As a tranſlator he was an enthuſiaſtic admirer of the original authors. He engaged in a controverſy with Perrault concerning the merit of the ancients and moderns, but was not conſidered as an able defender of the cauſe in which he engaged as an advocate. He was admitted a member of the academy of Inſcriptions, and afterwards was elected perpetual ſecretary to the French academy. He was likewiſe keeper of the cabinet of Louvre; theſe facts prove better than a thouſand eulogia, that he was a man of great worth, and unſullied integrity. He died in 1722. He took a part in the Medallic Hiſtory of Lewis XIV., for which he received a penſion. Moreri.

Dacier, Anne Le Fevre, wife of the preceding, and, as we have already obſerved, daughter of Tannegui le Fevre. She was born at Saumur, in the ſame year with her huſband; and was educated with the greateſt care by her father. At an early age ſhe became known as editor and commentator of ſome of the ancient claſſics in both languages. One of her firſt productions ſhe dedicated to the king, which he refuſed to receive from the hands of a proteſtant; the duke de Montauſier, who had introduced her to his ſovereign, was ſeverely reprimanded for encouraging the proſcribed ſect; jealous, however, of his maſter's honour, he took the liberty of expoſtulating with him, proving that he ought to be the patron of merit and talent, wherever, and among whomſoever found; and he added, that he would ſend Mademoiſelle Le Fevre a hundred piſtoles in his majeſty's name, which he might repay or not, as he ſhould judge proper. This circumſtance probably had ſome effect upon the change of ſentiments which M. Dacier and her huſband openly avowed ſoon after their marriage. She was a tranſlator as well as editor. Ariſtophanes, Anacreon, and Homer, were all rendered into French by this lady, ſome of which have been frequently reprinted and diſplay much merit. Notwithwithſtanding the high reputation to which ſhe attained in the literary world, ſhe was far from laying claim to any ſuperiority on that account: ſhe was modeſt and unaffected, but jealous of the honour of thoſe ancient writers whoſe merits ſhe wiſhed her countrymen to feel and acknowledge. She performed the duties of a wife and mother with exemplary affection, and exhibited in the loſs of a ſon of great promiſe, and of a darling daughter, the fortitude of a hero, and the reſignation of a true Chriſtian. She died in 1720, much eſteemed and regretted by all who knew her.

DACIO, in *Geography*, the laſt village in the kingdom of Italy, on the borders of Switzerland, and more particularly of the canton of the Griſons near the lake of Chiavenna.

DACIRA, in *Ancient Geography*, a town of Meſopotamia; called by ſome *Diacira*.

DACKENEM, or Dacquenem, in *Geography*, a town of Flanders, eight miles north-eaſt of Ghent.

DACOLITHUS, in *Ichthyology*, a ſpecies of *Cobitis*. See Cobitis *Tænia*.

DACRYDIUM, in *Botany*, (from δακρυ, a *tear*, or gummy diſtillation from a tree.) Solander in Forſter's Pl. Eſculent. 80, and Fl. Inſ. Auſtr. Prod. 92. Lambert Pin. 93. t. 41. Claſs and order, *diœcia monadelphia*. Nat. Ord. *Coniferæ*, Juſſ.

Gen. Ch. Male flowers forming an ovate terminal catkin. *Cal.* the ſcales of the catkin heart-ſhaped, pointed, bearing the anthers. *Cor.* none. *Stam.* Filaments none; anthers two to each ſcale, tranſverſe, orbicular, of two valves. Female flowers on a diſtinct plant, ſolitary, terminal. *Cal. Cor.* and *Style* unknown. *Nut* ovate, encompaſſed at the baſe by a dilated, firm, cup-ſhaped receptacle, and containing one ſeed.

Eſſ. Ch. Male. Calyx the ſcale of a catkin, bearing two ſeſſile anthers. Female. Nut ovate, ſeated in a cup-ſhaped receptacle.

Dacrydium cupreſſinum is figured in captain Cook's ſecond voyage, tab. 51, under the name of the Spruce Fir of New Zealand. It is ſaid to form large foreſts in the ſouth-weſt part of that country, to yield valuable timber, and to afford a kind of ſpruce beer. The leaves are ever-green, ſmall, crowded like thoſe of a *Lycopodium*; the branches elegantly pendent. Its height is from 50 to 100 feet. *D. taxifolium*, another New Zealand ſpecies, is mentioned by Hawkſworth in Cook's firſt voyage, v. iii. 441, as reſembling the Pitch Pine, and likely to make the fineſt maſts in the world, if the trees could be lightened by tapping.

DACRYODES, in *Surgery*, a term applied to ulcers, which are continually yielding a putrid matter.

The word is formed from δακρυ, *tear*, and ειδος, *form*; denoting the ulcers to weep, or ſhed ſomewhat like tears.

DACRYON. See Tears.

DACTYL, Dactylus, a foot in the Latin and Greek poetry, conſiſting of a long ſyllable, followed by two ſhort ones: as *cārmĭnĕ*; and *tenderly*, *haſtily*, in the Engliſh language.

Some ſay it is derived from δακτυλος, a *finger*, becauſe it is divided into three joints, the firſt of which is longer than the other two.

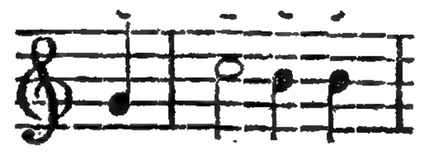
The dactyl is ſaid to have been the invention of Dionyſius or Bacchus, who delivered oracles in this meaſure at Delphos, before Apollo. The Greeks call it πολιτικος. The dactyl and ſpondee are the moſt conſiderable of the poetical feet; as being the meaſures uſed in heroic verſe, by Homer, Virgil, &c. Theſe two are of equal time, but not equal motion. The ſpondee has an even, ſtrong, and ſteady pace, like a trot: the dactyl reſembles the nimbler ſtrokes of a gallop. Paſſages in which the dactyl abounds afford a ſound, which is evidently and intentionally an echo to the ſenſe. Thus Homer (Odyſſ. l. xi.), after he has deſcribed in labouring ſpondees the ſlow and painful manner in which Siſyphus rolled the ſtone up hill, makes uſe of nimble dactyls in deſcribing its ſwift deſcent: thus,

"Αὖθις ἔπειτ' ἄπεδόνδε κυλίνδετο λᾶας ἀναιδὴς."

And Virgil (Æn. viii. v. 595, 596.) deſcribes in pure dactyls the galloping of the horſe: thus,

"——— It clāmŏr, ĕt āgmĭnĕ fāctō
Quādrŭpĕdāntĕ pŭtrēm Sŏnĭtū quătĭt ūngŭlă cāmpūm."

This term, in verſification, as much belongs to muſic as poetry, words frequently occurring in our language, (chiefly adverbs,) conſiſting of one long and two ſhort ſyllables; ſo that muſical movements in common time, when bars compoſed of one long and two ſhort notes frequently occur, it may be called *Dactylic muſic*, ſuch as Shenſtone's paſtorals generally require.



"My bānks thĕy wĕre fūrnĭſhed wĭth bēēs,
Whŏſe mūrmŭrs ĭnvīte mĕ tŏ ſlēēp."

Arne has ſet theſe words admirably in Siciliana time.

See

See the 2d ſtanza of this paſtoral ballad.

"Nŏt ă pīne ĭn thĕ grōve ĭs thĕre ſeēn," &c.

Shenſtone, vol. i.

DACTYLETHRA, or DACTYLITHRA, *Digitale*, among the *Ancient Phyſicians*, a medicine uſed to provoke vomiting. It was a ſort of topical application, and is deſcribed at large by Oribaſius.

DACTYLI, in *Antiquity*, a name attributed to the firſt prieſts of the goddeſs Cybele; who were particularly called *Dactyli Idæi*, on account of the goddeſs herſelf, who was ſtyled *Cybele Idæa*, becauſe principally honoured on mount Ida in Phrygia. The name *Dactyli* is ſuppoſed to have been given them on this occaſion: that to prevent Saturn from hearing the cries of Jupiter, whom Cybele had committed to their cuſtody, they uſed to ſing verſes of their own invention, which by their unequal meaſures ſeemed to reſemble the foot called *dactylus*.—This is the account of the grammarian Diomedes.

One Sophocles, quoted by Strabo, lib. x. ſpeaks differently. According to him they were called *Dactyli*, from the Greek word δακτυλος, *finger*, becauſe their number was at firſt equal to the fingers of the hand, *viz.* ten; five of them boys, and as many girls. He adds, that it is to them we owe the invention of iron, and the manner of working it, with divers other uſeful things, and for their uſeful diſcoveries, they are ſaid to have been worſhipped, after their death, as gods. Others make their number more, and others leſs than ten. Some, again, make them natives of Phrygia, near the foot of mount Ida; and others bring them from other places. According to Diodorus Siculus, they were the firſt inhabitants of Crete, who originally inhabited mount Ida, and paſſed from thence into Europe with king Minos. They ſettled firſt in Samothrace, where they taught the inhabitants ſacred rites, inſtituted ſacrifices, and introduced a ſet form of religious worſhip. Orpheus, who was naturally inclined to muſic and poetry, is thought to have been their diſciple, and the firſt who eſtabliſhed ſacred rites and ceremonies in Greece. However, all the authors Strabo had ſeen, he ſays, agreed, that they were the firſt who wrought in iron; that they had been miniſters of the mother of the gods, or Cybele; and that they dwelt at the foot of mount Ida: and they probably derived their knowledge of forging metals from the fuſion of minerals at the burning of mount Ida.

It is alſo conjectured by ſome authors, not that the Curetes and Corybantes were the ſame with the Dactyli Idæi, but that the Curetes and Corybantes were their poſterity; that a hundred men, born in Crete, were firſt called Dactyli Idæi; and that each of theſe had nine children, who were the Curetes; and that each of the Curetes had ten children, who were alſo called Dactyli Idæi. They were Cyclopians.

Strabo only gives us the names of four of the Dactyli Idæi, which are Salaminus, Damnanæus, Hercules, and Acmon. The learned Bryant, (Ancient Mythol. vol. i.) ſuppoſes that they were the ſame as the Curetes, Corybantes, Telchines, and Cabiri; which ſee reſpectively.

DACTYLIC, ſomething that has a relation to *dactyls*.

Anciently, there were dactylic, as well as ſpondaic flutes, *tibiæ dactylicæ*. The dactylic flutes conſiſted of unequal intervals; as the dactylic foot does of unequal meaſures.

DACTYLIC *verſes*, are hexameter verſes, ending in a dactyl, inſtead of a ſpondee; as ſpondaic verſes are thoſe which have a ſpondee in the fifth foot inſtead of a dactyl.

An inſtance of a dactylic verſe we have in Virg. Æn. lib. vi. 33.

"Bis patriæ cecidere manus: quin protinus omnia
Perlegerit oculis.——"

DACTYLIOMANCY, DACTYLIOMANTIA, a ſort of divination performed by means of a ring.

The word is compoſed of the Greek δακτυλος, *ring*, of δακτυλος, *finger*; and μαντεια, *divination*.

Dactyliomancy conſiſted principally in holding a ring, ſuſpended by a fine thread, over a round table, on the edge whereof were made divers marks with the twenty-four letters of the alphabet. The ring, in ſhaking or vibrating over the table, ſtopped over certain of the letters, which being joined together, compoſed the anſwer required.

But the operation was preceded and accompanied by ſeveral ſuperſtitious ceremonies; for firſt the ring was to be conſecrated with a great deal of myſtery: the perſon who held it was to be clad in linen garments, to the very ſhoes; his head was to be ſhaved all round; and in his hand he was to hold vervain. And before he proceeded on any thing, the gods were firſt to be appeaſed by a formulary of prayers, &c. Ammianus Marcellinus gives the proceſs at large in his twenty-ninth book.

DACTYLIS, in *Agriculture*, is a term ſometimes applied to a ſpecies of cultivated graſs, the rough cock's-foot graſs (*Dactylis glomerata.*) It is a coarſe hardy rough graſs, but which has been found highly uſeful on moiſt loamy ſoils, where the bottom is of the retentive clay-marl kind; and where other finer graſſes are apt to be overpowered by the natural herbage. It requires to be kept cloſely fed down; under which circumſtances it conſtitutes an excellent early ſheep feed. See GRASS, and GRASS *Land*.

DACTYLIS, in *Botany*, (from δακτυλος, a *finger*, in alluſion to the ſhape of its ſpikes.) Linn. Gen. 35. Schreb. 50. Willd. Sp. Pl. v. i. 407. Juſſ. 31. Claſs and order, *triandria digynia*. Nat. Ord. *Gramina*.

Gen. Ch. *Cal.* Glume of two valves, containing one or more florets, forming an oblong compreſſed ſpikelet; its valves unequal, pointed, keeled, convex, and broader on one ſide. *Cor.* Glume of two valves, the lowermoſt largeſt, concave, acute, pointed or awned; the other cloven, lanceolate. *Nectary* a pair of lanceolate, pointed ſcales, tumid at their baſe. *Stam.* Filaments three, capillary, longer than the corolla; anthers oblong, cloven at each end. *Piſt.* Germen ovate; ſtyles two, ſpreading; ſtigmas feathery. *Seeds* ſolitary, oblong, naked, with a furrow on one ſide, clothed for a while by the permanent corolla.

Eſſ. Ch. Calyx of two linear-oblong, compreſſed, keeled, unequal valves.

This genus of graſſes is not one of the beſt defined. It ought to have but a ſingle floret in each calyx, as in *D. ſtricta*, Engl. Bot. t. 380; *D. cynoſuroides*, Linn; and *D. patens*, Ait. H. Kew; which are genuine examples of it; but *D. glomerata*, Engl. Bot. t. 335, has three or four florets, and has thence been judged, by ſeveral botaniſts, not a good *Dactylis*. No one, however, has ſucceſsfully referred it to any other genus, nor is it adviſable to form a new one of this ſpecies alone, the ſtructure of its fructification being by no means ſufficiently diſtinct from the above-mentioned ſpecies. The *D. glomerata* thrives under the ſhade of trees. We have in the above article mentioned its agricultural properties; but we have no authority to recommend it for any agricultural purpoſe. If uſed for fodder, it muſt be cut while young and tender.

DACTYLONOMY, DACTYLONOMIA, from δακτυλος, *finger*, and νομος, *law*, the art of accounting, or numbering, by the fingers,

The rule is this; the left thumb is reckoned 1, the index

2,

2, and ſo on to the right thumb, which is the tenth, and of conſequence is denoted by the cypher o.

DACTYLS, in *Botany*, denotes the fruit of the palm-tree, more uſually called *dates*.

DACTYLUS, in *Antiquity*, a ſort of dance among the Greeks, chiefly performed, as Heſychius obſerves, by the athletæ.

Dactylus, in *Zoology*, a ſpecies of Pholas, in the claſs of *Vermes Teſtacea*. See Pholas.—Alſo, a ſpecies of *Voluta*, in the ſame claſs. See Voluta.

Dactylus *Idæus*, in *Natural Hiſtory*, a name given by many authors to the belemnites; ſuppoſed erroneouſly by many to be the *lyncurius* of the ancients.

DADACARDIM, in *Geography*, a town of Aſiatic Turkey, in the province of Diarbekir; 60 miles S. of Diarbek.

DADAI, a town of Aſiatic Turkey, in the province of Natolia, 40 miles E. S. E. of Amaſieh.

DADARI, a town of Hindooſtan, in the country of Delhi; 52 miles W. of Delhi.

DADASTANA, in *Ancient Geography*, a town of Aſia Minor, in Bithynia, at nearly an equal diſtance between Ancyra and Nice; where, according to Zoſimus, the emperor Jovian died Feb. 17, A. D. 364. It ſeparates Bithynia from Galatia, according to Arminianus Marcellinus.

DADDALA, a place of Aſia Minor, in Lycia. Ptol.

DADDI, Bernardo, in *Biography*, a painter, native of Arezzo, who was the ſcholar of Spinello, and became a member of the company of painters at Florence, in 1355. He painted the chapels of S. Lorenzo and S. Stefano dé Pulci, together with other works in the church of Santa Croce in that city. Little elſe is known of him except that he died in 1380. Baldinucci.

Daddi, Cosimo, a Florentine painter of the 16th and 17th centuries, who was a diſciple of Batiſta Naldini, and was employed in many conſiderable works by the court of Tuſcany. Amongſt others he painted in the *Coriile* of the Villa of Petraja, the heroic actions of Goffredo Buglione at the taking of Jeruſalem. The churches of Florence likewiſe poſſeſs ſeveral altar-pieces of conſiderable merit by his hand, and he was much eſteemed for his portraits, which generally proved ſtriking likeneſſes. He died at an advanced age, in 1630, having had the honour to inſtruct Baldaſſare Franceſchini, called Il Volterrano, in the firſt rudiments of his art. Baldinucci.

DADELER, in *Geography*, a town of Aſiatic Turkey, in the province of Caramania; 12 miles N. of Cogni.

DADEN, a town of Germany, in the circle of Weſtphalia, and county of Sayn, near which are ſome mines of copper; 8 miles S. of Siegen.

DADES Promontorium, in *Ancient Geography*, a promontory in the ſouthern part of the iſle of Cyprus, between the promontory Curias to the weſt, and that of Pedalium to the eaſt. Ptol.

DADICÆ, a people who, according to Herodotus (l. viii. 66.) lived in the vicinity of Sogdiana; and who were armed like the Bactrians.

DADIVAN, in *Geography*, a plain of Perſia, about 4 or 5 leagues in circumference, between Schiras and Lar, covered with trees of oranges, citrons, and pomegranates, to which the Engliſh and Dutch merchants of Ormus generally retire in the ſummer.

DADLEWALLET, a town in Africa, in the kingdom of Kontu.

DADO, in *Architecture*, the middle of a pedeſtal, or that part comprehended between the baſe and the cornice. In the pedeſtals of the orders this part has nearly a cubical form, whence it derives its name *dado*, Italian, for die.

Dado, in *Biography*, a fictitious artiſt, to whom ſeveral excellent prints of the 16th century, marked with a die, have been attributed. Many connoiſſeurs, however, conſider theſe plates to have been the work of Niccolo Beatricetto. Heinecken.

DADOU, in *Geography*, a ſmall river of France, in the department of the Tarn. It has its ſource near Saint Salvy, and runs into the river Agout below Lavaur.

DADUBRA, Dadibra, or *Dadybras*, in *Ancient Geography*, an epiſcopal town of Aſia Minor, in Paphlagonia.

DADUCHI, in *Antiquity*, prieſts of Ceres. See Ceres.

That goddeſs, having loſt her daughter Proſerpine, ſay mythologiſts, began to make ſearch for her at the beginning of the night. In order to do this in the dark, ſhe lighted a torch, and thus ſet forth on her travels throughout the world: for which reaſon it is, that ſhe is always ſeen repreſented with a lighted torch in her hand.

On this account, and in commemoration of this pretended exploit, it became a cuſtom for the prieſts, at the feaſts and ſacrifices of this goddeſs, to run about in the temple, with torches, after this manner: one of them took a lighted torch from off the altar, and holding it with his hand, ran with it to a certain part of the temple, where he gave it to another, ſaying to him, *Tibi trado;* this ſecond ran after the like manner, to another part of the temple, and gave it to the third, and ſo of the reſt.

From this ceremony the prieſts became denominated *daduchi*, δαδουχοι, q. d. *torch bearers;* from δας, an unctuous and reſinous wood, as pine, fir, &c. whereof the ancients made torches; and εχω, *I have, I hold.*

The Athenians alſo gave the name daduchus to the high-prieſt of Hercules.

DÆARA, in *Ancient Geography*, a place of Aſia, near to Apamea and almoſt E. of it, and S.W. of Anthemuſias.

DÆDALA, in *Antiquity*, two feſtivals in Bœotia, one of which was obſerved annually by the Platæans at Alalcomenus, where was the largeſt grove in all Bœotia. Here they aſſembled, and expoſing to the open air pieces of ſodden fleſh, carefully obſerved whither the crows that came to feed upon them took their flight, and then hewed down all thoſe trees on which any of them alighted, and formed them into ſtatues, which by the ancient Greeks were called *dædala*, δαιδαλα.

The other ſolemnity was by far the greateſt and moſt remarkable of the two, being celebrated only once in ſixty years, in commemoration of the exile of the Platæans, which laſted that number of years. For the ceremonies obſerved in it, ſee Pauſan. p. 302. in Bœot. and Pott. Archæol. Græc. lib. ii. cap. 20.

Dædala, in *Ancient Geography*, a country of India, the inhabitants of which abandoned it, and fled for ſhelter to the mountains, on the approach of Alexander the Great. The ſituation of this country, and alſo that of Acedera, which was deſerted in the ſame manner, are not preciſely aſcertained. Ptolemy places a town of this name on this ſide of the Ganges, in the country of the Caſpirians; lat. 30° 30′. —Alſo, a town of the iſland of Crete. Steph. Byz.—Alſo, a mountain of Lycia.—Alſo, a caſtle, according to Livy and Mela, or, as Pliny ſays, a town, of Aſia Minor, in Caria, ſituated in the northern part of the gulf of Glaucus, N. of Cape Cria, about lat. 36° 50′ or 55′. Stephanus Byzantius ſays, that Dædalus, being ſtung by a reptile, died

of the wound, and that this town, which was built in the place of his burial, took his name.

DÆDALEON Insulæ, two iſlands of Aſia, at the northern extremity of the gulf of Glaucus, on the coaſt of Caria.

DÆDALIA, a town of Italy, founded by Dædalus, according to Steph. Byz., who ſays that in his time it was called *Julia*.

DÆDALIUM, a place of Sicily on the ſouthern coaſt, S.E. of Agrigentum, and very near mount Ecnomus.

DÆDALUS, in *Fabulous Hiſtory*, the great grand-ſon of Erectheus, king of Athens, and grand-ſon of Eumolpus, or Eupalamus, or, as Ovid ſays, the ſon of Eupalamus, was eminently diſtinguiſhed as the moſt ingenious artiſt produced either in Athens or Greece. To him is aſcribed the invention of the axe, the ſaw, the plummet, the augre, and glue, and alſo of maſts and yards for ſhips. He alſo carved ſtatues with ſuch ſkill, that they ſeemed to be alive, and would move or fly from one place to another, unleſs they were chained. Having liberally educated Talus, called alſo Perdix, the ſon of his ſiſter, the ingenuity of his nephew, who is ſaid to have invented the turning-wheel, and other mechanical inſtruments, excited the jealouſy of Dædalus, and induced him to put Talus ſecretly to death. The murder being diſcovered, the Areopagus of Athens condemned Dædalus capitally, or, as Servius ſays, ſentenced him to perpetual exile. But whatever was the nature of his ſentence, he withdrew from Athens in diſguiſe, and retired with his ſon Icarus to Crete, where he was favourably received by king Minos. During his retreat in this iſland, he is ſaid to have conſtructed the famous labyrinth at Gnoſſus; and as he aſſiſted Paſiphae, the wife of Minos, in her licentious amours, he and his ſon were confined in this labyrinth; and finding no way of eſcape, he made wings for himſelf and Icarus with wax and the feathers of birds, and faſtening theſe wings to their ſhoulders, Dædalus flew out of Crete into Sicily, but Icarus, diſregarding his father's advice, and indulging the pride and wantonneſs of youth, ſoared too high, ſo that the ſun melted the wax that faſtened his wings, and he fell into the ſea, which, according to Ovid (Triſt. 1.), has from this circumſtance been called the Icarian ſea. From his plaſtic powers Lucretius deduces an epithet, which he applies to the earth, in order to deſcribe its vernal vegetation:

"—— Tibi ſuaves, *Dædala* tellus
Summittit flores."

DÆDIS, among the Greeks, a ſolemn feſtival that laſted three days, during all which time δαδες, or *torches*, were kept burning, which gave occaſion to the name.. The firſt was in commemoration of the pains of Latona, when ſhe was delivered of Apollo; the ſecond was in honour of the birth of Glycon, and the gods; and the third in memory of the marriage of Podelirius and the mother of Alexander.

DAELIKER, Johan Rudolph, in *Biography*, a portrait-painter of ſome eminence, who was born at Berlin in 1694. He afterwards ſettled in Switzerland, and died at Schaffhauſen in 1769. J. J. Hard has engraved from this artiſt a portrait of Johan Geſner, M.D.; and another of Johan Caſper Landoff, conſul of Zurich. Heineçken.

DÆMON, Δαιμων, a name the ancients gave to certain ſpirits, or genii, which they ſay appeared to men, either to do them ſervice, or to hurt them.

The Greek word, δαιμων, is derived (according to Plato, in his Cratylus, p. 398. ed. Serrani, vol. i.) from δαημων, *knowing*, or *intelligent*; but according to others from δαιομαι, *to diſtribute*. See the Scholiaſt on Homer, Il. i. ver. 222. Euſebius (Præp. Evang. l. iv. c. 5.) deduces dæmons from δειμαινειν, *to fill men with terror*; and as in the Greek language ε is often changed into α, we have thus the origin of δαιμων, *dæmon*, denoting any inviſible being that is an object of fear. Either of theſe derivations agrees with the office aſcribed to dæmons by the ancient heathens, as the ſpirits entruſted with the inſpection and government of mankind. For, according to the philoſophers, dæmons held a middle rank between the celeſtial gods and men on earth, and carried on all intercourſe between them; conveying the addreſſes of men to the gods, and the divine benefits to men. Plutarch de Defect. Orac. p. 415, *et ſeq.* Platon. Sympoſ. p. 202. tom. iii. ed. Serrani. Apuleius de Deo. Socrat. p. 674. 677. ed Delph. Iamblichus de Myſter. Auguſt. de Civ. Dei.

It was the opinion of many, that the celeſtial divinities did not themſelves interpoſe in human affairs, but committed the entire adminiſtration of the government of this lower world to theſe ſubaltern deities. "Neque enim pro majeſtate deum cœleſtium fuerit, hæ curare." Apuleius de Deo Socratis, p. 677. "Cuncta cœleſtium voluntate, numine & authoritate, ſed dæmonum obſequio, & operâ, & miniſterio fieri arbitrandum eſt." Id. p. 675. Hence they became the objects of divine worſhip. "If idols are nothing," ſays Celſus (apud Origen. cont. Celſ. lib. viii. p. 393.), "what harm can there be to join in the public feſtivals? If they are dæmons, then it is certain that they are gods, in whom we are to confide, and to whom we ſhould offer ſacrifices and prayers, to render them propitious."

Several of the heathen philoſophers held, that there were ſeveral kinds of dæmons; that ſome of them were ſpiritual ſubſtances of a more noble origin than the human race, and that others had once been men. Apuleius de Deo Socratis, p. 684. 690. Ammonius apud Plutarch. de Defect. Orac. p. 431. tom. ii. ed. 1624. Plato in Timæo, p. 41, 42. 69. 71. 75.

Thoſe who maintain the former of the above-mentioned opinions, allege that the primary gods, whoſe exiſtence was conſidered as prior to the creation of man, and whoſe original is always connected with the formation of the earth, the elements, and the heavenly bodies, are frequently ſtyled dæmons by the ancient Greek writers, and more eſpecially by Homer (Il. i. v. 222.); who, as Plutarch (de Orac.) obſerves, indifferently uſes theſe two words, ſometimes calling the gods dæmons, and the dæmons gods; and indeed he applies both terms in the ſame ſentence to one deity. (Il. xvii. v. 98.) The proſe writers alſo uſe the term dæmon in the ſame ſenſe. Thus, Xenophon (Memorab. l. i. c. 4. l. iv. c. 3.) calls him the dæmon, who is able to diſcern and regulate all things, both at hand and at the greateſt diſtance, in the ſame moment, and with the utmoſt care; and who ſhews himſelf to be unwearied, perfect, incorruptible, adminiſtering quicker than thought, and without error. The advocates of this opinion further obſerve, that the ſupreme deity of the Pagans is called the greateſt dæmon; to which argument it has been replied, that notwithſtanding the magnificent titles by which the Heathens deſcribe their ſupreme deity, they yet repreſent him as having a father and mother, a grand-father and grand-mother, and being of the ſame kindred with the other gods of whom he was chief. See Homer's deſcription of Jupiter in Iliad. i. v. 398. and Lucian. Deor. Dialog. apud Oper. vol. i. The other Heathen writers, and Heſiod in particular in his Theogony, give a

ſimilar

ſimilar repreſentation of Jupiter; aſcribing to him the prerogatives, titles, and epithets of their ſupreme natural divinity; and at the ſame time clothing him with the weakneſſes, vices, and all the properties of a human being: ſo that he ſuſtained the two characters of a natural and of a hero-god. According to the Pagan ſyſtem of theology, deified human ſpirits appear to have been aſſociated with and to have repreſented the natural gods, and they were both called by the ſame names. The ſun, æther, or air, or whatever other part of nature was eſteemed the ſupreme deity of Pagans, was called in Egypt Oſiris, in Chaldæa and Phœnicia, Bel or Baal; and in many other countries, Jupiter: and it is univerſally known, that Jupiter, Bel, and Oſiris, had once been mortal men, who were ſuppoſed to be advanced after death to a deified ſtate. For the ſame reaſons, therefore, for which the chief Heathen numen was called Oſiris, or Bel, or Jupiter, he might be called a dæmon; ſuppoſing the word to denote a deified human ſpirit; and it is ſaid, that under this laſt character he was principally regarded by the common people. It has been ſaid, however, that no deciſive evidence can be produced in order to prove, that religious honours were ever paid to any deceaſed man, under the names of Bel, the ſupreme deity of the Chaldæans, or Oſiris, the numen of the Egyptians, or that ſuch worſhip was ever paid to a human ſpirit, under the name of Jupiter: and, indeed, it is certain that the Heathens worſhipped many gods that had never been men. The Heathens, it is ſaid, never conſidered any part of nature as their ſupreme deity; the Egyptians worſhipped the ſun and moon under the names of Oſiris and Iſis, and never paid any religious honours to hero-gods; and under the name Bel, who is ſaid by Beroſus to have formed the ſtars and the ſun, the Chaldæans worſhipped what had never been a man; as did alſo the Greeks, under the appellation of Jupiter.

It is farther urged by thoſe who maintain the ſuperior rank and nature of dæmons, that they are deſcribed as beings placed between the gods and men. But, on the other hand, it is argued, that this deſcription reſpects not their nature but their office, as mediators between men and the celeſtial gods, and therefore agrees with ſuch human ſpirits as were thought to be advanced to the office of dæmons. Jamblichus (apud Stob. Eclog. Phyſic. lib. i.) ſays, that good men were recompenſed at death by being converted into angels and angelical ſouls, meaning the ſame as dæmons; and it is allowed by the learned, that Jamblichus, Hierocles, Simplicius, and others, uſe the word dæmons and angels indiſcriminately. Hierocles ſays expreſsly (In Carm. Pythag.), that the middle kinds of beings were called indifferently angels, or dæmons, or heroes; and as the latter were human ſpirits, it is preſumed that the former belonged to the ſame claſs. Philo ſays (De Gigantibus), that ſouls, dæmons, and angels, are only different names, but imply one and the ſame ſubſtance; and in another place (De Somn.) he affirms, that Moſes called thoſe *angels*, whom the other philoſophers ſtyled *dæmons*. It is farther argued, on the one ſide, that dæmons are expreſsly diſtinguiſhed from heroes, who were the departed ſouls of men; and on the other, that dæmons were advanced to a rank and ſtation ſuperior to that of heroes, and that this difference occaſioned the diſtinction. Accordingly thoſe who adopt this opinion contend, that thoſe dæmons who were the more immediate objects of the eſtabliſhed worſhip amongſt the ancient nations were human ſpirits, ſuch as were believed to become dæmons or deities after their departure from their bodies. Plutarch teaches (Vit. Romul.), "that according to a divine nature and juſtice, the ſouls of virtuous men are advanced to the rank of dæmons; and that from dæmons, if they are properly purified, they are exalted into gods, not by any political inſtitution, but according to right reaſon." In his book (De Defect. Orac.) he ſpeaks of human ſouls as commencing firſt heroes, then dæmons, and afterwards advanced to a more ſublime degree. He adds (De Iſ. et Oſir.), "that Iſis and Oſiris were, for their virtue, changed from good dæmons into gods, as were Hercules and Bacchus afterwards, receiving the united honours of both gods and dæmons." Theſe ſentiments of Plutarch are confirmed by other writers, as Diodorus Siculus, and Pauſanias in Corinthiac. l. ii. c. 10. Heſiod, and other poets, who have recorded the ancient hiſtory or traditions, on which the public faith and worſhip were founded, aſſert that the men of the golden age, who were ſuppoſed to be very good, became dæmons after death, and diſpenſers of good things to mankind.

This account of dæmons is fully confirmed by the other writings of the ancient heathens; and many paſſages have been cited from theſe wri ings by ſeveral learned men, particularly by Mr. Joſ. Mede, and Dr. Sykes, in which dæmons muſt have the ſame meaning as in Heſiod. It is not pretended, that the heathens did not acknowledge and worſhip celeſtial or natural gods; for the deſcription of dæmons as the more *immediate* objects of worſhip of itſelf implies, that there were *ultimate* objects of it, who could be no other than thoſe celeſtial gods, whoſe agents and miniſters the former were ſuppoſed to be. Moreover, it is ſuppoſed that ſome dæmons, or ſubaltern deities, either celeſtial or terreſtrial, were acknowledged and worſhipped in the nations to which the inquiry extends, and particularly among thoſe that were in the moſt civilized and poliſhed ſtate, and even in moſt of thoſe nations that were reckoned barbarous. Among the nations poliſhed by learning we may reckon the Chaldæans, Babylonians, Syrians, Phœnicians, Egyptians, Greeks, Romans, and alſo ſuch Arabians as bordered upon India and Egypt. That in theſe nations divine honours were paid to dead men and women is ſtrenuouſly maintained by Mr. Farmer, whoſe reſearches on this ſubject have been very ample and various. Philo of Byblus, who tranſlated the hiſtory of Sanchoniathon from the Phœnician language into Greek, has given in his preface to it, the following extract from his author "The moſt ancient of the barbarians, eſpecially the Phœnicians and Egyptians, from whom other people derived this cuſtom, accounted thoſe the GREATEST GODS, who had found out things moſt neceſſary and uſeful in life, and had been benefactors to mankind. Theſe they worſhipped as gods; and, applying their temples to this uſe, they conſecrated to their names pillars and ſtatues of wood, which the Phœnicians held in high veneration, and inſtituted the moſt ſolemn feſtivals in their honour. More eſpecially did they give the names of their kings to the mundane elements, and to other things to which they attributed divinity. For phyſical beings alone, ſuch as the ſun, moon, planets, and elements, and things of the ſame kind, did they acknowledge to be ſtrictly and properly gods. So that ſome of their gods were MORTAL, and others IMMORTAL." Hence it is deduced, that the Phœnicians and other ancient nations, worſhipped ſuch men as had been benefactors to the human race. Moreover, Euſebius, who has preſerved part of Philo's tranſlation in his Præp. Evang. l. i., teſtifies, that, even to his time, deified men and women were the gods worſhipped by all people, and in all cities and countries. It is farther maintained by the learned writer now cited, that heroes and gods of earthly origin were worſhipped by the Egyptians. Hermes Triſmegiſtus (*vid.* Auguſt. Civ. Dei,

l. xxviii. c. 26.), acknowledged, that the gods of Egypt were dead men; that the art of making gods was invented in this country; and that human ſouls were worſhipped as dæmons in every city. Herodotus, who had viſited Egypt, and who had taken pains in informing himſelf concerning the religion of that country, records ſeveral inſtances of the worſhip of human ſpirits in that country; though they ſeem to have been overlooked by Dr. Blackwell, (Letters on Mythology, p. 209.) and Jablonſki, (Pantheon Egypt. tom. 2. Prolegom. p. 37.) who affirmed, upon the ſuppoſed authority of this hiſtorian, that the Egyptians paid no religious honours to any gods of earthly extract. Herodotus has alſo recorded ſeveral facts, which ſerve to ſhew, that ſome at leaſt of all the different orders of Egyptian gods were no other than men and women deified. From Diodorus Siculus we learn, that the Egyptians, beſides the ſun and moon, whom they called the *firſt* and *eternal gods*, acknowledged ſuch as *were taken from the earth*; ſeveral of whom, he ſays, *had been kings of Egypt*, and *bore the ſame names with the celeſtial gods*, (p. 14. 17. Ed. Weſſel.) He particularly ſpecifies the eight great gods of Egypt, *Sol*, *Saturn*, *Rhea*, *Jupiter*, (called alſo *Ammon Juno*, *Vulcan*, *Veſta*, and *Mercury*). Iſis and Oſiris, the two principal divinities in Egypt, were, according to Diodorus, king and queen of Egypt; and he informs us, that Oſiris conquered the moſt diſtant nations; that he deified his parents; and that he was himſelf deified in his turn, and had a third part of the lands appropriated to maintain his worſhip; and that after his death he received equal honour with that paid to the celeſtial gods. (p. 24.) From Plutarch (Iſ. et Oſir.) we learn, that the prieſts affirmed, that the bodies of their gods, except ſuch as were incorruptible and immortal, lay buried with them; and he gives us at large the hiſtory of the parentage of Iſis and Oſiris, their birth, their kindred, their exploits, and their death. Mr. Farmer has appealed to ſeveral other authorities, ſuch as thoſe of Plato, Lucian, Maximus Tyrius, Varro, Apuleius, and Lucan, in proof of the fact, that the worſhip of human ſpirits prevailed in Egypt. Upon the whole he concludes, that the Phœnicians and Egyptians, though they acknowledged elementary and ſidereal deities, and aſſerted more eſpecially the divinity of the ſun and moon, did alſo worſhip human ſpirits; and that the Egyptians worſhipped them under the diſtinct characters of heroes, dæmons, and gods. It farther appears, ſays this ingenious writer, that both the Phœnicians and Egyptians accounted their princes and eminent benefactors as *the greateſt gods*. The twelve great gods of Egypt, in particular, as well as the Cabiri of Phœnicia and the eaſtern nations, were dead men deified. He infers from the teſtimonies which he has adduced, that deified men were the *immediate* objects of the public eſtabliſhed worſhip in Egypt, as they alſo were in Phœnicia. He proceeds to ſhew, that the cuſtom of deifying human ſpirits prevailed among the Aſſyrians, Chaldæans, and Babylonians. As the religion of Aſſyria and Babylon was derived from Egypt, which was probably the caſe, the former muſt have been in a great meaſure the ſame with that of the latter, which conſiſted, in part, in the worſhip of human ſpirits. The Chaldæan idolatry, called alſo the *Sabian*, conſiſted very much, at leaſt originally, in the worſhip of the ſun, moon, and ſtars, which were conceived to be ſeverally animated by a ſoul, as the human body is; and, probably, they were alſo thought to be inhabited by the ſpirits of illuſtrious men. The chief god of the Babylonians was *Bel*, called by the Greeks *Belus*, anſwering to the Hebrew *Baal*, and to the Syrian *Beel*, and ſignifying *lord*. This term might therefore be applied to the true God; but it is commonly given in Scripture to thoſe fictitious deities, who were falſely ſuppoſed to have dominion over mankind. Some have ſuppoſed that Bel, who was worſhipped at Babylon, was the creator of heaven and earth, as the true God; but as the Babylonians had been for many ages before the time of Alexander, when Beroſus, who has particularly mentioned Bel as having framed the world, &c., was the prieſt of Belus, were groſs idolaters, they were not likely to worſhip the creator of heaven and earth; and ſome circumſtances are related concerning this Belus, which are altogether inconſiſtent with this high denomination and character. Bel, indeed, was a name or title given to ſeveral princes; and more eſpecially to the founder of the Babylonian empire. If he be, as ſome have ſuppoſed, the Nimrod of the Bible, he was ranked amongſt the gods by the Perſians, who ſucceeded to his empire; whence we may infer, that he was firſt worſhipped at Babylon; and Euſebius informs us, that Belus, the firſt king of the Aſſyrians, was deified after his death. It is not to be inferred from the account given of Belus, that the term *Bel* was never explained phyſically, and applied to the ſun, by learned men, as Oſiris alſo ſometimes was; for the ancients gave the names of their deified kings to the heavenly bodies. But the temple of Babylon was erected in honour of a man who founded the Babylonian empire, agreeably to the cuſtom of the Heathens in the like caſes. And this Belus was the god whom the Babylonians principally worſhipped. (See Baal, Baalim, and Babylon.) The Aſſyrians and Babylonians had ſeveral other gods of mortal origin, and it appears upon the whole, that dead men and women were the more immediate objects of the public devotion at Babylon, and were indeed honoured as their greateſt gods. From the teſtimony of Lucian (De Dea Syr.) it appears, that the gods of Syria were of two ſorts; the one viſible, particularly the ſun and moon; the other inviſible, that is, human ſpirits, or ſuch deities as correſponded to the idea which the Greeks had formed concerning thoſe objects of worſhip that belonged to the human race, and were repreſented by ſtatues; and we have ſufficient reaſon for believing, that the Syrians deified dead men and women.

Mr. Farmer has traced at large the mythology of the barbarous nations, and cited a great number of teſtimonies and facts in order to ſhew that the worſhip of human ſpirits prevailed among the Scythians, the Maſſagetes, the Getes, the Goths, the Germans, the Perſians, the Arabians, and the inhabitants of Meroe. This is alſo the caſe with regard to ſeveral barbarian nations in Africa, the Celtes both of Aſia and Europe, and ſeveral nations of Aſia. But for particulars we muſt refer to the author himſelf.

It is well known, and univerſally allowed, that the natural gods, the ſun and moon in particular, were adored by the Greeks, as well as by the barbarians. It muſt alſo be admitted, that the Greeks worſhipped the firſt founders of ſtates and cities; thoſe who died in defence of their country; and ſuch as were greatly diſtinguiſhed by their talents and exploits. But it is altogether unneceſſary, in ſo plain a caſe, to produce the various proofs of the deification of men in Greece, which occurs continually in Herodotus, Pauſanias, Plutarch, and other Greek writers. The law ordained, that the gods, the dæmons, and the heroes, ſhould be worſhipped according to their reſpective ranks. Mr. Farmer is of opinion, that the twelve great gods of Greece, or as they are ſometimes called, the gods of the greater nations, were of human extraction. In proof of this opinion, he alleges the following arguments. 1. The Greeks derived their religion from Phœnicia and Egypt; eſpecially from the latter. 2. The teſtimony of Herodotus, who was,

without

without doubt, well acquainted with the Grecian objects of worſhip. This hiſtorian informs us (l. i. c. 131.) that the reaſon why the Perſians did not erect temples, altars, and images, to the gods (which the Greeks were known to do) "was, in his opinion, their not believing, as the Greeks did, that the gods are of the race of men." The ſtatues of the gods, in human form, ſays our author, were a proof of their having been men. The Greeks acknowledged the ſame natural gods as the Perſians did; but in Perſia they worſhipped the natural gods themſelves, directly and immediately; whereas, in Greece, the more immediate objects of the public worſhip were deified human ſpirits, to whom the adminiſtration of the government of this lower world was thought to be committed. And as theſe preſidents over nature did, as it were, intercept and engroſs the public devotion, Herodotus might juſtly ſay, in general terms, that the Greeks believed their gods were of human origin. And as Herodotus is here ſpeaking of the principal objects of Grecian worſhip, or of thoſe to whom the title of gods eminently belonged, who had temples, chapels, images, and altars, erected in their honour: he muſt therefore include the 12 great gods of Greece, and conſequently affirm, that they were dead men and women deified. 3. That the gods of the greater nations were deified mortals is a point partly eſtabliſhed by the "Sacred Hiſtory of Euhemerus of Meſſina." Euhemerus relates, that in one of his voyages, undertaken by order of Caſſander, king of Macedonia, he came to an iſland called Panchaia, and there found, in the temple of the Triphilian Jupiter, an authentic regiſter of the births and deaths of the gods, ſeveral of which are ſpecified by name, and mentioned by Diodorus Siculus. in a fragment preſerved by Euſebius. (Diod. Sic. Fragm. ad Weſſel. Euſeb. Præp. Evang. l. ii. c. 2. Cicero de Nat. Deor. l. i. c. 42.) The deſign of this "Sacred Hiſtory" was to ſhew, that the gods were to be regarded as mortal men. This hiſtory has been ſanctioned by the moſt reſpectable writers of antiquity: it was tranſlated into Latin, and approved by Ennius, Cicero, Diodorous Siculus, Euſebius, St. Auſtin, Lactantius, Minucius Felix, and Arnobius. But Euhemerus, it has been ſaid, was branded as an atheiſt: and this circumſtance has been urged to diſcredit the truth of his doctrine concerning the humanity of the gods. To this objection it has been replied, that no man was deemed an atheiſt by the heathens, if he worſhipped any gods who intereſted themſelves in the affairs of mankind, though they were only ſuch as had been men. So far, indeed, was the deification of men from implying atheiſm, that it rather preſuppoſed the exiſtence of the natural gods, with whom the deified men were aſſociated, and from whom they derived their power and authority. Hence it has been inferred that Euhemerus was not ranked among the atheiſts merely for aſſerting, that thoſe worſhipped by the people as gods had once been men. The charge againſt Euhemerus was his believing, that there were no gods, or none who take care of mankind. (Ælian. Var. Hiſt. l. ii. c. 31. Plut. de Placit. Phil. l. i. c. 7.) This charge, however, might be founded on his rejection of the received notion of the popular gods, juſt as Socrates, for a ſimilar reaſon, was deemed an atheiſt; and accordingly Sextus Empiricus informs us (Adv. Phyſicos, l. ix. c. 2. § 17.) that he repreſented their pretended deification as the mere effect of the pride and policy of princes and great men, in order to procure a higher veneration for their perſons, and a more ready ſubmiſſion to their authority. Moreover, Plutarch grounds the charge of atheiſm againſt him, not upon his aſſerting that the gods had been men, but upon his maintaining that they were nothing more than men long ſince dead. To this purpoſe Clemens Alexandrinus (Cohort. ad Gentes, tom. 1.) ſays, that Euhemerus and others were called atheiſts, "becauſe they had the ſagacity to diſcover the error of other men concerning the gods;" that is, they clearly ſaw they were not real divinities. The only plauſible objection, it is ſaid, againſt the hiſtory of Euhemerus, is that which Plutarch has urged, *viz.* that no one beſides this hiſtorian had ever ſeen the iſland of Panchaia. The exiſtence of this iſland, however, has been acknowledged by others, as Pomponius Mela, Diodorus Siculus, and Ptolemy Euergetes. Upon the whole it may be obſerved, that if the doctrine of Euhemerus, charged by Plutarch with ſpreading atheiſm through the world, and impugning the exiſtence of all the received gods without diſtinction, whom he deſcribed merely as ancient generals, admirals, and kings, be true, then even the great gods of Greece were men and women, who were, without any reaſon, ſuppoſed to become gods after death. Beſides, from a particular enumeration of the ſeveral Grecian deities, and an examination of their reſpective hiſtory, and of the character and attributes aſcribed to them, it is inferred that the origin of each of them was human. This was the caſe with reſpect to Jupiter, and of courſe as to the other gods and goddeſſes, who were of the ſame family, and of whom he was chief. In regard to the Greeks, it is concluded, that however they might acknowledge the natural gods, yet the dead men and women, whom they deified, were the more immediate and principal objects of their public worſhip. As the Romans derived their religion from Greece, Ægypt, and the Eaſt, it is natural to imagine that there ſhould be a conformity between their objects of worſhip, and thoſe of the other nations, in which dead men and women were deified. Accordingly we find that Æneas, from whom the Romans claimed deſcent, brought from Troy into Italy his houſehold gods, who were the ſouls of his departed anceſtors, and the great gods, who probably were the Samothracian deities, ſtyled "Cabiri," or great and powerful divinities, natives of Phœnicia. Hence it has been inferred, that, both in the country he had left, and among his own deſcendants in Italy, gods of human origin were worſhipped, and repreſented by ſacred images. Among other laws reſpecting religion, Numa ordained the following: "Let all honour the ancient gods of heaven, and thoſe whoſe merits have carried them thither: ſuch as Hercules, Bacchus, Æſculapius, Caſtor, Pollux, and Quirinus. (Cicero de Legibus, l. ii. c. 8.) To theſe ſix more may be added in later times, who are univerſally allowed to have been men, but who were eminently diſtinguiſhed from many other heroes, by being admitted into the community of the celeſtial or olympian gods. Numa required both theſe orders of deities to be worſhipped by the people: and hence it appears that the Romans acknowledged mortal gods. The law of Numa became a law of the 12 Tables, and remained in force in all ſucceeding times; whence it follows, that human ſpirits were, in every age, worſhipped at Rome, and even were the principal objects of the eſtabliſhed worſhip in that city; for the ancient gods of heaven, ſpoken of in the laws of the 12 Tables, were no other than the following 12 ſuperior gods of the Romans:

Juno, Veſta, Minerva, Ceres, Diana, Venus, Mars,
Mercurius, Jovis, Neptunus, Vulcanus, Apollo.

And theſe were the ſame with the 12 ſuperior gods of the Greeks, who were no other than deified men and women. Varro, the moſt learned of all the Romans, aſſerted, as St. Auguſtine informs us, that one would be at a loſs to find, in

the writings of the ancients, *gods* who had not been men. Cicero contends, (Tuſc. Quæſt. l. 1. c. 12.) "that the whole heaven was almoſt entirely filled with the human race; that even gods of the ſuperior order, or gods of the greater nations, were originally natives of this lower world, &c." (See alſo Cicero De Nat. Deor. l. i. c. 42.) Cicero's teſtimony is confirmed by St. Auſtin (Civ. Dei, l. viii. c. 26. c. 5.), who ſays, "You cannot find, or can hardly find, in all the writings of the Heathens, any gods but ſuch as had been men; nevertheleſs, to all of them they pay divine honours, as if they had never belonged to the human race." It was upon the principles of the ancient theology that the Roman people deified their emperors; nor was this cuſtom of deifying great princes an innovation of the Romans, but it was an old ſuperſtition, which prevailed to ſuch a degree, that even the Chriſtian emperors permitted themſelves to be addreſſed, "as gods adored by the nations, to whom the world preferred their public and private vows." It has been farther argued, that the worſhip of human ſpirits prevailed among the heathens, from various teſtimonies of the ancients, and from certain uncontroverted facts. The heathen poets, whatever are the titles with which they dignify the objects of their eſtabliſhed worſhip, do nevertheleſs record their birth, parentage, and kindred, and aſcribe to them thoſe paſſions, external forms, and various properties, which belong to human nature, and which ſubſiſt among mankind. (See Cicer. de Natur. Deor. l. i. c. 16. l. ii. c. 28. Tuſcul. Diſput. l. i. c. 26.) The worſhip appointed by the laws was conformable to the poetic theology, and founded upon it. Moreover, the painters and ſculptors convey to us the ſame ideas of the heathen deities as the poets, for they repreſent them under human figures, both male and female.

If an appeal be made to the opinions of the philoſophers, concerning the gods, they will be found to have been infinitely various. Nevertheleſs, we may deduce from their teſtimony what were the objects of national worſhip, and this affords ſufficient evidence of the general worſhip of human ſpirits. Indeed, all the different ſects of the philoſophers eſtabliſh this fact. The heathen hiſtorians not only bear teſtimony to the worſhip of human ſpirits in particular countries, but furniſh general proofs of the prevalence of this worſhip among the ancient heathens. (See Diod. Sic. Fragm. tom. ii. p. 633. ed. Weſſel. Polyb. Hiſt. l. vii. p. 512. ed. Caſaub.) The learned Bryant (ſee Anal. Anc. Mythol. vol. i. p. 454, &c.), whilſt he allows, that the Pagan gods were not only ſuppoſed by Chriſtian writers to have been deified mortals, who were worſhipped in the countries where they died, but that this was the opinion of the heathens themſelves, the very people by whom theſe gods were honoured; yet contends that this was a miſtake; and that moſt of the deified perſonages, mentioned by the Greek writers, never exiſted, but were mere titles of the deity, the ſun. This hypotheſis reſts principally upon two grounds; one of them being etymological deduction, which is, in various caſes, precarious and unſatisfactory; and the other, the writings of the Greeks, whoſe teſtimony he himſelf has taken pains to diſparage.

If we examine the opinion of the Jews concerning the Heathen Gods, we ſhall find that the writers of the Old Teſtament, in particular, though they knew that the Pagans believed in ſidereal and elemental deities, yet properly deſcribe their gods as *dead* perſons, becauſe it was to ſuch that the public worſhip was more immediately directed. In deſcribing the Heathen gods as dead perſons, they conſider them as what they *really were*, not what they were *conceived to be* by their worſhippers, for theſe regarded them as men advanced to divine power and dominion. (See Deut. xxvi. 14. Pſ. cvi. 28, compared with Numb. xxv. 1, 2, 3. Iſ. viii. 19.) In contradiſtinction from theſe, the ancient prophets called Jehovah the only *living* God. (See Deut. v. 26. Joſh. iii. 10. 1 Sam xvii. 26. 2 Kings, xix. 4. Jerem. x. 10. Dan. vi. 26, &c. &c.) The Jews, who were the authors of the Septuagint verſion, ſtyle the Heathen gods dæmons. (Deut. xxxii. 17. Pſ. xcv. 6. Pſ. cvi. 37.) The Chriſtian fathers are very generally agreed in maintaining that all the Heathen deities had been men and women; ſo that it is needleſs to multiply citations from their writings to this purpoſe This, as Mr. Bryant allows, was the opinion of Clemens, Euſebius, Cyril, Tertullian, Athenagoras, Epiphanius, Lactantius, Arnobius, Julius Firmicus, and others; among whom we may reckon Cyprian, Minucius Felix, and St. Auſtin.

The opinion and teſtimony of the fathers ſeem to be of great weight in the determination of this queſtion. They were bred up in the heathen religion, or lived in the times when it flouriſhed; and therefore were as competent judges as the Heathens themſelves could be. After critical examination they confidently pronounced the objects of national worſhip to be human ſpirits. They ſupported this opinon by arguments more than by the authority or conceſſions of the Heathens. And ſo clear and cogent were their reaſonings, that idolaters deſerted the worſhip of their falſe gods, and adored only the Creator of heaven and earth.

The teſtimonies already adduced, in order to prove that all the Heathen gods (except the deified parts and powers of nature) had been men, are confirmed by indiſputable facts, and particularly by the nature of the worſhip paid to the heathen deities. If no argument can be drawn from the ſacrifices which were offered them; yet their images, columns, ſhrines, reliques, altars, or grave-ſtones; and temples (which were their ſepulchres) afford ſufficient proofs, that the objects of public worſhip were ſuch dead men and women as ſuperſtition deified. Even funeral rites were performed in their honour. As a juſt idea of the heathen gods is a matter of no ſmall importance in its reference to conſiſtent views of religion, and a ſatisfactory defence of the Scripture, we have extended this article beyond the uſual limits aſſigned to ſubjects of this nature. By the account above given of the pagan gods, we are enabled to vindicate the cenſure paſſed upon them in the ſacred writings. As to the parts and powers of nature which the heathen world deified, they are repreſented in ſcripture as the creatures of God's power, and the paſſive inſtruments of his decrees: nor can we forbear obſerving, that, at a time when the world was univerſally regarded as animated and divine, and the elements and the heavenly bodies were thought to poſſeſs an internal power to exert themſelves in all their admirable effects, Moſes diſcovered, publiſhed, and, by ſuitable miracles, confirmed the oppoſite doctrine. This doctrine, ſo perfectly agreeable to the principles of modern philoſophy, and ſo remote from the ſentiments and philoſophy of his age, affords a ſtrong preſumption of his having received it by immediate revelation. As to the other gods of paganiſm, whether they were ſuch human ſouls as became dæmons, or created ſpirits of a ſuperior order, as ſome apprehend; the ſcripture (we conceive) gives us ſuch a view of them as is inconſiſtent with their inſpiring prophecies or working miracles. The ſacred writers ſeem conſtantly to repreſent theſe gods as utterly impotent and inſignificant; either as having no real exiſtence, or no more power than if they did not exiſt. They call them "vanities," or things of no value or efficacy, and this degrading repreſentation is extended to all of them without exception. (See Deut.

xxxii. 21. 1 Kings, xvi. 13, 26. Jerem. viii. 19, x. 8. xiv. 22. xviii. 15. 1 Sam. xii. 21. Pſ. xxxi. 6. xcvi. 5. Job, xiii. 4. Iſaiah, xli. See alſo Levit. xix. 4. 1 Chron. xvi. 26. Ezek. xxx. 13, and compare 1 Kings, xviii. 27. Iſ. xlv. 5.) The apoſtles of Chriſt uſe the ſame language concerning them with that of the ancient prophets. (1 Cor. viii. 4. x. 19.) The heathens, indeed, aſcribed oracles, prophecies, and prodigies to their dæmons; and on their favour the good or evil ſtate of men's lives was thought to depend: and this perſuaſion was the ground of their worſhip. Hence it appears, that the proper point in diſpute between idolaters and the prophets of the true God was, whether that perſuaſion was ſupported by facts. The meſſengers of God challenge idolaters to juſtify their worſhip of idols, and the idol gods themſelves to give proof of their divinity by a diſplay of knowledge, or by ſome exertion of power, ſuch as was either hurtful or beneficial to mankind; and even admit that, by ſuch a diſplay of their power or knowledge, the heathen deities would have eſtabliſhed their claim to divinity, and their title to the homage of mankind. (See Iſaiah, xli. 21, 24.) Their utter impotence appears to be the only reaſon of the Scripture's remonſtrating againſt paying them homage. Theſe circumſtances are frequently repeated and juſtified by facts. (See Jerem. x. 3, 5, 15. Iſ. xliii. 8. xliv. 7. xlv. 16, 20. xlvi. 5. xlviii. 3. 1 Cor. viii. 4. x. 19. xii. 2. 1 Theſſ. i. 9. Dan. iv. 7. v. 7. 1 Kings, xviii.)

It has been aſſerted, and ſtrenuouſly maintained by ſome writers of approved talents and learning, that the ſyſtem of pagan idolatry was ſupported by miracles and prophecies, performed and delivered, not by the fictitious deities of the heathens, but by "devils," or, wicked dæmons of a higher order than mankind, who perſonated the gods, lurked within their conſecrated images and ſtatues, inſpired the vates, animated the fibres of the entrails of victims, governed the flight of birds, guided the lots, framed the oracles, and exerted themſelves to the utmoſt in promoting idolatry, in order to involve men in the guilt of it, to draw all adoration to themſelves, to ſecure proper food and nouriſhment from the evil ſteams and blood of the victims which were offered to them, and hereby to ſtrengthen themſelves for the enjoyment of their luſtful pleaſures with boys and women. Theſe wicked ſpirits, it has been aſſerted, were, properly ſpeaking, the gods of the heathens, rather than thoſe imaginary beings whom they ſeemed to themſelves to worſhip. In ſupport of theſe aſſertions an appeal has been made to the writings of the fathers, and the authority of ſcripture; and it muſt be allowed that extravagant opinions of this kind are clearly contained in the writings of the fathers. (Juſt. Mart. Apol. p. 113. ed Thirlbii. Tertullian de Anima, c. lvii. Minucius Felix, c. xxvii. Cyprian. de Idolor. Van. p. 206. Arnob. cont. Gent. l. i. 26. Lactant. de Orig. Error. l. ii. c. 16. de verâ Sapient. l. viii. c. 16. Euſeb. Præp. Evang. l. v. c. 4. Auguſt. de Civ. Dei. l. viii. c. 16. See alſo Middleton's Free Enquiry, p. 66, 70, 77, and Mede's Works, p. 680, 681.) The Fathers, however, though they ſometimes taught or allowed, that pagan idolatry was ſupported by oracles and miracles, do nevertheleſs on other occaſions confeſs, or clearly intimate, that paganiſm had no other ſupport than human craft and impoſture. (Origen cont. Celſum. Euſeb. Præp. Evang. l. iv. c. 1, 2, 3. Clem. Alexand. Strom. Arnob. l. vi. Lactant. l. ii. See Fontenelle's Hiſt. of Oracles, c. ix. and Clerici Hiſt. Eccles. prolegom.) We have already ſuggeſted the improbability that the Scriptures ſhould aſſert or allow that idolatry was ſupported by the miraculous interpoſition of any wicked ſpirits; whether they did or did not counterfeit the ſouls of men deceaſed: and the ſubject, as it is peculiarly intereſting to the biblical critic, will be again reſumed for farther diſcuſſion.

Dæmon is often uſed, in a general ſenſe, as equivalent to a *deity*; and is accordingly applied to *fate* or *fortune*, or whatever elſe was regarded as a god; yet thoſe dæmons, who were the more immediate objects of divine worſhip amongſt the heathens, as Mr. Farmer maintains, and as we have already ſtated his ſentiments and reaſoning, were human ſpirits.

The word dæmon is uſed indifferently in a good and in a bad ſenſe. In the former ſenſe it was very commonly uſed amongſt the ancient heathens, "We muſt not," ſays Menander, "think any dæmon to be evil, hurtful to good life, but every god to be good." Plato (Cratyl. tom. 1. p. 398. ed. Serrani) commends Heſiod and the other poets, who affirmed, that whenever any good man died "he became a dæmon." He elſewhere (de Republ. tom. ii. l. v. p. 468.) ſpeaks to the ſame purpoſe. "All thoſe who die valiantly in war are of Heſiod's golden generation, and become dæmons; and we ought for ever to worſhip and adore their ſepulchres, as the ſepulchres of dæmons" He affirms the ſame concerning all who were judged excellently good in life, in whatever manner they die. The common or conſtant uſe of dæmon in the earlieſt ages, in a good ſenſe, unleſs when κακος, or ſome ſimilar epithet, is joined with it, is owing, ſays Mr. Farmer, to its being applied at firſt to the deified ſouls of good men; and if the firſt dæmons were all good, as Dr. Sykes aſſerts, it is becauſe the firſt men (whoſe ſouls they were), the men of the golden age, were all good: becauſe the heathens thought that the ſeparated ſpirits of good and bad men became reſpectively good and bad dæmons. Nevertheleſs, thoſe are certainly miſtaken who affirm, that dæmon never ſignifies an evil being till after the times of Chriſt. Pythagoras held dæmons who ſent diſeaſes to men and cattle. (Diogen. Laert. Vit. Pythagor. p. 514. ed Amſtel.) Zaleucus in his preface to his laws (apud Stobæum. Serm. 42.) ſuppoſes that an evil dæmon might be preſent with a man, "to influence him to injuſtice." The dæmons of Empedocles were evil ſpirits, and exiles from heaven. (Plutarch Περι του μη δειν δανειζεσθαι.) And in his life of Dion (p. 958.) he ſays, "It was the opinion of the ancients, that evil and miſchievous dæmons, out of envy and hatred to good men, oppoſe whatever they do. Scarcely did any opinion more generally prevail in ancient times than this, *viz.* that as the departed ſouls of good men became good dæmons, ſo the departed ſouls of bad men became evil dæmons. See Chalcid. in Platon. Tim. cap. 135. p. 330.

Accordingly δαιμονιος frequently occurs in ancient writers as a term of reproach as well as of praiſe; whatever may be the opinion we adopt with regard to the nature and rank of dæmons. It has been very generally ſuppoſed, that dæmons, and particularly the bad dæmons, were ſpirits of a celeſtial origin; and this application of the term frequently occurs both among the heathens and in the ſcriptures; and more eſpecially in the writings of the Chriſtian fathers. When no bad quality is aſcribed to the dæmon, or dæmons that are mentioned, and nothing is affirmed concerning them which implies it, the acceptation of the term in Pagan writers is generally favourable. The Jews, and as ſome ſay, the ſacred writers, and alſo the Chriſtian fathers, commonly uſed the term in a bad ſenſe. But Mr. Farmer maintains, that, whether the term dæmon be uſed in a good or bad ſenſe, there is no ſufficient reaſon for reſtricting it to ſpirits of a higher order than mankind. As the ſouls of many good men,

men, he ſays, were thought to become good dæmons after death, ſo it was a prevailing opinion that the departed ſouls of many bad men became bad dæmons. Thales, Pythagoras, Plato, and the Stoics, as we learn from Plutarch (De Placit. Philoſ. l. i. c. 8.) repreſented "heroes as ſouls ſeparated from their bodies, and as being good or bad according to their reſpective characters." No notion, he adds, was more prevalent in the Heathen world, from the earlieſt ages, than that of the power of ghoſts to haunt and torment mankind, particularly the ghoſts of thoſe who died a violent death; and hence he inclines to believe that the doctrine of the philoſophers concerning evil men's becoming evil dæmons after death was the creed of the vulgar. From the Heathens the ſame or ſimilar opinions paſſed to the Jews, whoſe doctors taught "that the ſouls of the damned are for ſome time changed into devils, in order to be employed in tormenting mankind." (See Calmet's Dictionary, Art. *Dæmon*; Theophylact cited by Grotius in Matt. viii. 28.) Joſephus ſays expreſsly (De Bell. Jud. l. vii. c. vi. § 3.) "that dæmons were the ſpirits of wicked men." Aſmodeus (who is often deſcribed as the prince of evil ſpirits, and reckoned the very ſame as Sammael and Beelzebub) is repreſented by the Jews as having for his mother Nahemah, the ſiſter of Tubal-Cain. Some of them taught that dæmons were the offspring of Sammael (the prince of dæmons), and Eve, before Adam knew her. (See Calmet, *ubi ſupra.* Vandale de Idolat. Buxtorf's Lexic. Chald. Talmud. Baſnage's Hiſt. of the Jews, b. iv. c. 11.)

It is not eaſy to aſcertain, whether dæmon is uſed in a good or bad ſenſe in the LXX. If we could determine this point, we might infer how the term ſhould be underſtood in the New Teſtament, the writers of which have adopted the ſtyle and diction of the LXX. That it was uſed, at leaſt generally, in a bad ſenſe, ſeems to be probable for the following reaſons. Some of the Heathens themſelves inferred from the actions aſcribed to their gods, and the rites by which they were appeaſed, that they were not gods, but evil dæmons. (Plut. de Iſ. Oſir. De Defect. Orac. Compare Porphyr. de Abſtin. l. ii. § 36, 37. 42.) The Jews who wrote in the Greek language uſe dæmon in a bad ſenſe, particularly Joſephus and the tranſlator of Tobit, ch. iii. 8. vi. 17. Grotius (in Matth. iv. 14.) thought that the Helleniſts uſed δαιμων in an ill ſenſe, as the Hebrews did Baal; though both originally indifferent in their ſignification. Moreover the New Teſtament does certainly, on ſome occaſions, by dæmons mean evil ſpirits (Matth. x. 34. James, ii. 19.); and therefore the word may have the ſame meaning when it is applied to the heathen gods. Whatever notion we entertain concerning dæmons, in their reference to poſſeſſion, whether we ſuppoſe them to be ghoſts of wicked men deceaſed, or lapſed angels, it is plain they were conceived to be malignant ſpirits. They are exhibited as the cauſes of the moſt dreadful calamities to the unhappy perſons whom they poſſeſs, dumbneſs, deafneſs, palſy, madneſs, epilepſy, and ſimilar diſorders. They are frequently called πνευματα ακαθαρτα, unclean ſpirits, ſometimes πνευματα πονηρα, malign ſpirits. They are repreſented as conſcious that they are doomed to miſery and torments, though their puniſhment be for a while ſuſpended. It has been generally thought that by *dæmons* we are to underſtand *devils*, in the Septuagint verſion of the Old Teſtament. Accordingly the Iſraelites are charged by Moſes (Deut. xxxii. 17.) with the aggravated idolatry of ſacrificing unto *devils* (ſchedim), whom he calls "new gods that came newly up, whom they knew not, and their fathers feared not;" and the pſalmiſt (Pſ. cvi. 37.) reproaches them in ſimilar terms; "Yea, they ſacrificed their ſons and daughters unto devils" (ſchedim); and in another place (Pſ. xcvi. 5.) it is ſaid "all the gods of the nations are idols." In theſe three paſſages the term uſed by the Septuagint is δαιμονια. If all the pagan gods were devils, ſays Mr. Farmer, why are the *Schedim* diſtinguiſhed from their other gods? Why are they called new to the Iſraelites, who had of old worſhipped the pagan deities? (Gen. xxxv. 2, 4. Joſh. xxiv. 2.) Why is the worſhip of theſe *Schedim* mentioned as matter of peculiar reproach? And if theſe *Schedim* were devils, who have a real and extenſive power over mankind, why are they called *vanities* and *idols?* (Deut. xxxii. 2. Pſ. xcvi. 5. cvi. 36.) The word *ſchedim*, as this author ſays, is derived from a verb, which ſignifies to lay waſte, to deſtroy, and ought to have been rendered *the deſtroyers*. It expreſſes the ſuppoſed cruel nature and character of theſe falſe gods, who were thought to delight in, and who were accordingly worſhipped by, the deſtruction of the human ſpecies, and who required as appears from the context (Pſ. cvi. 38.) even "the blood of their ſons and daughters." Who the gods were that were worſhipped by human ſacrifices all hiſtory informs us; and ſo has the plaſmiſt in the moſt expreſs terms, "they ate the ſacrifices of the dead:" they were the great warriors who in their mortal ſtate delighted in the ſlaughter of the human race. This worſhip was new to the Iſraelites, as they had never practiſed it in Egypt or before they went into that country; but what they afterwards learned of the Canaanites. Accordingly the *ſchedim* are expreſsly called by the pſalmiſt (Pſ. cvi. 38.) "the idols of Canaan." What one circumſtance is there, adds our author, that can lead us to ſuppoſe that either Moſes or the Pſalmiſt, in the forecited paſſages, is ſpeaking of *devils*, in the common acceptation of that word? On the other hand, it is alleged that *ſchedim* is derived from a verb, which ſignifies to pour forth, to ſhed, to ſcatter abroad, and ought to be rendered *diſtributors*. Theſe were the idol gods of Canaan, *viz.* Baal, the ſun, moon, planets, and all the hoſts of heaven, as the ſcriptures repeatedly aſſure us; nor doth Moſes mention any other idol gods: whence, it is ſaid, it muſt be obvious to unprejudiced perſons, that the terms *ſchedim* in the Old Teſtament, and dæmons in the New, are applied to thoſe gods which had never been men, and cannot denote deified human ſpirits. (Fell's Dæmoniacs, p. 71.)

There is another paſſage in the Old Teſtament (Levit. xvii. 7.) in which our Engliſh tranſlators have introduced the word *devils*, "they ſhall no more offer their ſacrifices unto devils," לשעירם, to *ſeirim* or *ſchirim*, a word which ſignifies hairy beings, or goats. The learned Bochart has ſhewn, that the ſacred animals of Egypt were hairy, and that the goat in particular was worſhipped; ſo that, as the *ſchedim* were the idols of Canaan, the *ſeirim* were the idols of Egypt. That this was the caſe appears from another paſſage in which the ſame word occurs, *viz.* 2 Chron. xi. 15. But the word *ſeirim* (goats) no more ſignifies *devils* than any other word throughout the Bible. This prohibition of Moſes to the Iſraelites, after they had left Egypt implies, that they had, during their ſtay there, defiled themſelves with the particular ſpecies of idolatry here condemned. And the other paſſage, in which it is ſaid that Jeroboam "obtained him prieſts for the high places, and for the devils, and for the calves he had made," obviouſly denotes, that Jeroboam lately returned from Egypt, eſtabliſhed the worſhip of the deities of that country, which was eminently that of goats and calves, or at leaſt ſet up the images of theſe animals as ſymbols of the divinity. It could not refer to *devils*, in the ſenſe now given to the word, becauſe the Iſraelites are never charged by their prophets with ſo deteſtable a ſpecies of idolatry as the worſhip of devils; nor did the Egyptians, whoſe example Jeroboam copied, ever repreſent devils under the figure of goats and calves.

calves. Upon the whole Mr. Farmer concludes, that the authors of the Septuagint verſion muſt have known that the Heathen gods, which were the immediate objects of worſhip, and which are repeatedly called dæmons, and not devils, were deified men; and what he has offered on this head is much confirmed by what occurs in ſir Iſaac Newton's Chronology, p. 160, 161.

In the New Teſtament alſo the Heathen deities are called dæmons; though the Engliſh tranſlation tends to miſlead the reader by the uſe of the word devils inſtead of dæmons, which the original imports; and hence, as well as from ſome other collateral conſiderations, it has been inferred, that the Heathen deities were ſpirits of an order ſuperior to that of the human race, and alſo that they belonged to the claſs of wicked ſpirits. Thus we read in 1 Cor. x. 20, 21. "that the things which the Gentiles ſacrifice, they ſacrifice to *devils*, and not to God; and I would not that ye ſhould have fellowſhip with *devils*;—ye cannot drink the cup of the Lord, and the cup of *devils*; ye cannot be partakers of the Lord's table and the table of *devils*." The word here rendered *devils* is δαιμονια, or *dæmons*; but allowing this to be the caſe, it has been maintained that the word dæmon being uſed in an ill ſenſe, the dæmons here referred to were apoſtate angels. On the other hand, Mr. Mede and others are of opinion, that dæmons might have been taken in a good ſenſe; and it has been ſuppoſed that the apoſtle is deſcribing, in this paſſage, the objects of popular worſhip, and ſpeaking of the notion which the Heathens in general had of them; thus "they ſacrifice to dæmons," that is, to ſpirits whom they regard as real deities. But it has been ſaid, that if theſe dæmons were evil ſpirits, they might nevertheleſs have denoted deified men and women. How immoral were the characters, and how licentious was the worſhip, of thoſe gods that were certainly of human extract, ſuch as Jupiter, Venus, Bacchus, and many others? Oſiris or Serapis was the chief of evil dæmons (Plutarch, tom. ii. p. 362.) To theſe, it is ſaid, there may be a reference in 2 Cor. vi. 14—16; particularly in the expreſſion, "what concord hath Chriſt with Belial?" The Heathen dæmons might be called Belial, either becauſe they were of no uſe (deducing it from בלי, *nihil*, and יעל, which in Hiphil denotes *prodeſſe*, or becauſe ſo much wickedneſs entered into the idea which the pagans entertained of them. St. Paul, it is alleged, was not unacquainted with the Greek learning, and it may be preſumed that he could not be ignorant of the ordinary ſignification of dæmons amongſt the Greeks. Nay, it is farther affirmed by Mr. Farmer, that he did know, that the Greeks by this word expreſſed gods taken from among men. After preaching to the Athenians concerning the reſurrection and glory of Jeſus Chriſt, they repreſented him as "a ſetter forth of ſtrange dæmons or gods;" (Acts, xvii. 18, 22.) which, as our tranſlators have intimated, could not mean *devils*, in the ordinary acceptation of the term, but muſt denote *deified men*; the Athenians imagining that St. Paul was recommending a new deity, who had once been a man. It cannot be ſuppoſed that in his addreſs to the Athenians, whom he wiſhed to conciliate, and not to irritate, when he calls them δεισιδαιμονεστερους, or very devout towards dæmons or the gods, he ſhould brand them as worſhippers of devils; an affirmation of that kind not being true, nor likely to be underſtood by the Athenians in that ſenſe. In another paſſage (1 Tim. xiv. 1.) St. Paul, foretelling the apoſtacy of ſome profeſſing Chriſtians from the purity of the original faith, ſpecifies, among ſeveral other inſtances, this very remarkable one, "their giving heed to doctrines" (not of *devils* but) "concerning dæmons." Here the apoſtle evidently refers to the worſhip of *Saints* practiſed by idolatrous Chriſtians; as biſhop Warburton allows (Serm. vol. iii. p. 302.) though not in perfect conſiſtency with another declaration (Serm. vol. ii. p. 70.) "that the ſacred writers never uſe the word *dæmons*, but they always mean Satan and his angels." The meaning of the apoſtle may be inferred from this paſſage, which ſhews that by the word *dæmons* he did not mean *devils*, but beatified or deified human ſpirits.

The apoſtle James ſays (ch. ii. 19.), "The devils" (in the original, the dæmons) "believe and tremble." Here, ſays Dr. Campbell, the apoſtle means the ſpirits of wicked men deceaſed; and he further obſerves, that in this epiſtle, the epithet δαιμονιωδης is accordingly uſed in a bad ſenſe, (ch. iii. 15.), where that wiſdom which produceth envy and contention is ſtyled earthly, ſenſual, deviliſh or dæmonian. Mr Farmer ſuggeſts, that this paſſage of St. James is taken from one in the book of Job (xxvi. 5.), the words of which he tranſlates, "the giants tremble under the waters (or in *the abyſs*), *together with their* hoſt or fellow-inhabitants." The word רְפָאִים, he ſays, ſometimes ſignifies the ghoſts of the dead in general. (Pſ. lxxxviii. 10. Iſ. xxvi. 14.) In other paſſages it ſeems to denote the ghoſts of wicked men in particular, who are in a ſtate of perdition; and more eſpecially, perhaps, thoſe of the giants who periſhed by the flood, and thoſe who, like them, filled the earth with violence and terror. (Prov. ii. 18. ix. 18. xxi. 16. Iſ. xiv. 9.). Rephaim properly ſignifies giants in Gen. xiv. 5. Deut. ii. 11. 20. iii. 11. Joſh. xv. 8. xvii. 15. 2 Sam. xxi. 16. 18. 20. 22. 1 Chron. xx. 4. 6. 8. In the paſſage cited from Job, it is explained concerning giants, that is, their ghoſts in the Chaldee Paraphraſe, the Septuagint, the Latin Vulgate, and many modern verſions. In the phraſe "under the waters," Mr. Peters (Diſſ. on Job, p. 359.) and others, ſuppoſe that it refers to the waters with which the giants were overwhelmed at the flood. (See Mede Diſc. on this text, Works, p. 31.). This expreſſion, "under the waters," anſwers to the loweſt hell, or ſheol, in Deut. xxxii. 22. or that part of ſheol which is allotted to wicked ſouls. (See Peters on Job, ſect. 8. Windet, de Vitæ Functorum ſtatu, p. 204. 243.) Accordingly, Mr. Farmer apprehends, that the dæmons of St. James anſwer to thoſe departed ſouls in Job, whether you underſtand thereby the ghoſts of the wicked in general, or thoſe of the antediluvian giants in particular. From this paſſage he infers, that by dæmons in the New Teſtament we are ſometimes to underſtand the ghoſts of dead men. In another paſſage (Rev. ix. 20.), he ſuppoſes it can bear no other meaning; where St. John refers to the idolatries practiſed in the Romiſh church, which conſiſt in the worſhip of departed ſaints and ſenſeleſs idols, not of *devils*, as this word is now underſtood. In the ſequel of the revelation of St. John, he had a prophetic viſion of "the ſpirits of dæmons working miracles," which is referred by ſome to the miracles pretended to be wrought by departed ſaints, and in ſupport of their worſhip, and underſtood by others as a ſymbol or figurative repreſentation of the deceit and fraud practiſed by men of the temper and ſpirit of dæmons, in ſupporting their claims to a miraculous power. Another paſſage occurs in the book of Revelations (ch. xviii. 2.), in which the utter deſolation of Babylon is deſcribed: "It is become the habitation of dæmons;" *i.e.* a deſert; dæmons or evil ſpirits being ſuppoſed to frequent deſolate places, (compare the LXX. verſion of Iſ. xiii. 21; and ſee Vitringa on Rev. xviii. 2.)

Such as we have enumerated are the occaſions on which dæmons, not directly referring to poſſeſſions, occur in the

New Teſtament; from a diſtinct examination and illuſtration of which, Mr. Farmer concludes, that the term dæmons never means in them the devil and his angels; but that dæmons denoted the ghoſts of dead men; and that the word was uſed, as the ancients uſed it, ſometimes in a good, and at other times in a bad ſenſe. For the cuſtomary uſe of the term in its connection with poſſeſſions, ſee the article DÆMONIAC.

As to the meaning of the word dæmon in the fathers of the Chriſtian church, it is uſed by them in the ſame manner it was by the heathen philoſophers, eſpecially the latter Platoniſts; that is, ſometimes for departed human ſpirits, and at other times for ſuch ſpirits as had never inhabited human bodies. In the fathers, indeed, the word is more commonly taken in an evil ſenſe than in the ancient philoſophers; and it has been a very general opinion, that by dæmons they meant fallen angels, as well as the ſouls of dead men, both being objects of worſhip among the heathens. To this purpoſe, Lactantius ſays *(ubi infra)*, "Triſmegiſtus calls dæmons evil angels; ſo well was he acquainted with this, that they had been celeſtial beings, but were depraved, and ſo were become terreſtrial." He alſo affirms "that there are two ſorts of dæmons, the one celeſtial, the other terreſtrial; that the latter are the authors of the ill things that are done, whoſe prince is the devil, whom Triſmegiſtus calls the dæmonarch," (prince of dæmons.) Chryſoſtom (in Pſ. xli. tom. v. p. 137.) reckons it among the favours of Providence, that when the air is full of dæmons and adverſe powers we do not diſcern them; for the ſight of them might frighten us out of our wits, if not to death. Euſebius of Cæſarea (Præp. Evang. l. vii. c. 16.) ſuppoſed theſe ſpirits to be fallen angels; and he ſays, that when they had ſinned, and for their tranſgreſſion were expelled the heavenly abodes, many of them were thruſt into hell, called the abyſs, and confined there; others of them were ſuffered to dwell near the moon, and in the region of the air, &c.

Mr. Farmer, whilſt he allows that the heathens believed in the exiſtence of dæmons of a purely celeſtial nature, ſome of whom were evil ſpirits, denies that the heathens worſhipped any ſuch beings as we call fallen angels; and as to the opinion of the fathers, he obſerves, that they conſtantly maintain that Saturn, Jupiter, Serapis, Æſculapius, and all the heathen gods, had been mortal men; and that, therefore, they contradicted themſelves, when they aſſerted that they were a different order of beings. If they admitted that they had all been men, with what truth or conſiſtency could they call them fallen angels? Mr. Farmer conceives that the fathers borrowed this language from the Pagan philoſophers: and both urge, in ſupport of their aſſertion, that thoſe beings whom the heathen world worſhipped as gods were evil dæmons, the ſame arguments; ſuch as the actions aſcribed to the heathen gods, the rites appointed to placate them, and their oppoſition to the cauſe of true piety. Both taught that evil dæmons were ſpirits of a celeſtial origin, and that they were inſpirers and authors of prophecies and miracles. As the fathers had been educated in the ſchools of pagan philoſophy, they would naturally adopt the ſentiments and language of the philoſophers, and retain them after they embraced Chriſtianity. Nevertheleſs, attached as they were, by early education or habit, to the pagan ſyſtem of dæmonology, ſome of them maintained, and Juſtin Martyr in particular, that dæmons were the ſouls of dead men. This was alſo the caſe with regard to Athenagoras, Tatian, Tertullian, and others.

Beſides the two forementioned kinds of dæmons, the fathers, as well as the ancient philoſophers, held a third, *viz.* ſuch as ſprang from the congreſs of ſuperior beings with the daughters of men. In the theology of the ancients, theſe were the worſt kind of dæmons. (Tertullian's Apology, cap. 22. Lactantius, Div. Inſtitut. lib. ii. cap. 14. 15.) Tertullian here refers to "the ſons of God," in the hiſtory of Moſes (Gen. vi. 2.), who mixed with the daughters of men, and who were believed to be angels by Juſtin Martyr (Apolog. ii. p. 112.), Tertullian, and by almoſt all the fathers of the four firſt centuries, upon the authority of Joſephus (Antiq. i. 4.), Philo (vol. i. p. 263.), and the ancient editions of the Septuagint, which had ſubſtituted "the angels of God," inſtead of "the ſons of God."

Different orders of dæmons had different ſtations and employments aſſigned them by the ancients. Good dæmons were conſidered as the authors of good to mankind; evil dæmons brought innumerable evils both upon men and beaſts. Amongſt evil dæmons there was a great diſtinction with reſpect to the office aſſigned them; ſome compelled men to wickedneſs, others ſtimulated them to madneſs. On the ſubject of this article, ſee, beſides the original writers already cited, Banier's Mythology, vol. i. b. v. Blackwell's Letters on Mythology. Mede's Works. Farmer's Diſſert. on Miracles. Eſſay on Dæmoniacs. Worſhip of Human Spirits. Lardner's Works, vol. i. Bp. Newton's Works, vol. iv. diſſ. xv. See DÆMONIAC.

DÆMON, or *Genius of Socrates*, a ſort of preceptor or monitor, whoſe counſel and aſſiſtance he is ſaid to have experienced in the chief concerns and actions of his life. This genius ſuggeſted to him what courſe it was proper for him and others to avoid, and diverted him, and thoſe who regarded his advice, from the proſecution of enterpriſes which would have proved prejudicial, without ever prompting him to any particular action. Cicero (De Divin. l. i.) deſcribes this dæmon as "Divinum quoddam, quod dæmonum appellat, cui ſemper ipſe paruerit, nunquam impellenti, ſæpe revocanti." Plutarch and Apuleius have compoſed ſeparate treatiſes on this genius or dæmon of Socrates, in which they ſtate the ſentiments of the ancients concerning its exiſtence and nature. As the deity alone has a clear and unerring knowledge of futurity, thoſe who are the moſt ſagacious in diſcerning the courſe and iſſue of events, and their effect in contributing to the ſucceſs or miſcarriage of any enterpriſe, approach the moſt nearly to divinity, and ſeem, according to human judgment, to participate, in ſome degree, the counſels and deſigns, the foreſight and preſcience of the deity himſelf; although their knowledge of futurity is conjectural and precarious, whilſt his is certain and infallible. Socrates poſſeſſed a very conſiderable portion of this ſagacity, in the exerciſe of which he blended a juſt and penetrating judgment with the moſt conſummate prudence. Accordingly he might denominate this kind of ſagacity δαιμονιον, ſomething divine, adopting a ſort of equivocal expreſſion, and modeſtly declining to arrogate to himſelf the merit of his wiſdom in conjectures concerning futurity. The abbé Fraguier, in a diſſertation on this ſubject, printed in the fourth volume of the "Memoirs of the Academy of Belles Lettres," aſcribes the whole of what has been ſaid concerning the dæmon of Socrates, to the wiſdom and prudence of that philoſopher, which enabled him to foreſee many things which a perſon of inferior diſcernment would never have thought of; for prudence, ſays Cicero, is a kind of divination. If Socrates had not intended to decline aſſuming to himſelf the merit of an unerring judgment, by attributing it to a kind of inſtinct; and if he had pretended to any extraordinary gift ſuperior

a foreſt conſecrated to the Eumenides. Sophocles, according to Suidas, was born in this place.

COLONUS, an huſbandman, or villager, who was bound to pay yearly a certain tribute, or at certain times of the year, to plow ſome part of the lord's land; and from hence comes the word *clown*, who is called by the Dutch *boor*.

COLONY, Colonia, is properly a number of perſons of all ſexes and conditions, tranſported into a remote province, with a view of remaining there, and for the purpoſe of cultivating and inhabiting it; but among commercial nations, the term is uſed in a larger but leſs proper ſenſe, and applied to the temporary reſidence of merchants and agents in another country. The word colony originally ſignified no more than a *farm*, i. e. the habitation of a peaſant, *colonus*, with the quantity of land ſufficient for the ſupport of his family; "quantum colonus unus arare poterat." It is derived from the Latin word *colo*, I till or cultivate; hence *colonus*, a huſbandman, and *colonia*, a body of farmers, ſent to cultivate the ground in a diſtant country, and, by metonymy, the place itſelf. From the Latin the word has paſſed, with ſcarcely any alteration, into the modern languages of the weſt of Europe.

We may diſtinguiſh, generally, four kinds of colonies; *viz.* 1. Thoſe that ſerve to eaſe or diſcharge the inhabitants of a country, where the people are become too numerous, ſo that they cannot any longer conveniently ſubſiſt together. 2. Thoſe eſtabliſhed by victorious princes and people, in the middle of vanquiſhed nations, to keep them in awe and obedience. 3. Thoſe that are formed by emigrants, driven from their native country by oppreſſion and perſecution to ſeek a foreign ſettlement, and to ſubſiſt firſt by agriculture, and afterwards by commerce. 4. Thoſe that may be called "colonies of commerce;" becauſe trade is the ſole occaſion and object of them.

To the *firſt* claſs we may refer the colonization which took place in the earlier ages of the world, and which ſerved to diſſeminate the human race, firſt through the various regions of the eaſt, and afterwards through other more remote parts of the globe. At this early period colonization was of courſe more frequent than it is at preſent. The increaſe of a tribe beyond the limits of a comfortable ſubſiſtence upon the lands which were occupied, would be a ſufficient motive for inducing the younger members of the ſociety to remove from the proſpect or actual preſſure of want, to ſome unoccupied territory. Some authors, however, are of opinion that ſoon after the deluge, when the deſcendants of Noah became numerous, a diviſion of the ancient continent and its adjacent iſlands was made, probably by lot, among the heads of the ſeveral families. This opinion ſeems to be in ſome meaſure ſupported by the authority of Moſes, who ſays, (Gen. x.) on mentioning the children of Eber, that the name of one of them was "Peleg" (diviſion), for in his days was the earth divided." (See Dispersion.) However this be, the gradual extenſion of the habitations of mankind muſt have correſponded with their increaſe; and it ſeems to have been unreſtrained by claims made upon the uncultivated ſpots. But this unlimited right of diſperſion has long ſince ceaſed in moſt parts of the world; and hence it has become neceſſary for coloniſts, who ſeek new ſcenes for their labours, either to unite with the natives as friends, or to ſubdue them by conqueſt, if the colony is founded upon hoſtile principles. At a ſubſequent period, the different ſtates of ancient Greece, ſuch were Athens, Sparta, Corinth, and Argos, poſſeſſed territories of very limited extent; and the increaſe of population gave riſe to various emigrations from all thoſe ſtates. The colonies of the Dorians reſorted chiefly to Italy and Sicily, which, in the times preceding the foundation of Rome, were inhabited by barbarous and uncivilized nations; thoſe of the Ionians and Eolians, the two other great tribes of the Greeks, to Aſia Minor and the iſlands of the Ægean ſea, the inhabitants of which ſeem at that time to have been pretty much in the ſame ſtate as thoſe of Sicily and Italy. The emigrations now mentioned, and ſome others of a ſimilar nature, were undertaken by private individuals, with no authority from the government; and as they were generally directed towards diſtant and tranſmarine ſettlements, they retained but a ſlight connection with their original countries. The parent ſtate, indeed, conſidered the colony as a child, at all times entitled to great favour and aſſiſtance, and owing in return much gratitude and reſpect; but, moreover, conſidered it as an emancipated child over whom no direct authority or juriſdiction was claimed. The colony ſettled its own form of government, enacted its own laws, elected its own magiſtrates, and made peace or war with its neighbours as an independent ſtate, which had no occaſion to wait for the approbation or conſent of the parent city. The coloniſts, indeed, remembered the land of their fathers with filial affection and reſpect; they honoured its gods, by offerings of firſt-fruits to their temples; they retained a predilection for its cuſtoms and laws, as well as its religion and language; they yielded to its citizens the place of diſtinction at public games, and to its prieſts the holy honour of firſt inſpecting the entrails of ſacrifices. In war they generally followed the fortunes of the metropolis, as allies upon equal terms; but as they were perfectly independent, received no protection from her, and often equalled her in reſources, they always refuſed to come forward as auxiliaries, when unfair terms were propoſed. Thus, the Sicilian colonies refuſed to admit an Athenian army into their territories, for the purpoſe of reſting, on an expedition; and, in the Perſian war, the republic of Syracuſe, when intreated by the Lacedæmonians to aid the common cauſe, refuſed to ſend any aſſiſtance, unleſs their chief magiſtrate, Gelon, were allowed to command the united forces. Sometimes the parent country, conſcious of her ſuperiority and ſtrength, attempted to exact from the colonies, as matter of right, the uſual marks of filial attachment. Thus, Corinth was deſpiſed by her colony at Corcyra, for her inferiority of wealth and trade; and ſhe endeavoured to obtain by force, the uſual tokens of remembrance. The coloniſts appealed to Athens, who took their part, and retained them as uſeful allies, eſpecially during the Peloponneſian war. Potidæa, another Corinthian ſettlement, took the part of Athens, until her impolitic tyranny urged it to throw off the yoke, and appeal to Sparta and Corinth. After a long and ſevere ſtruggle, the Athenians were ſucceſsful; ſent new colonies to occupy the confiſcated and vacant lands; continued their oppreſſive government; and retained their dominion over Potidæa, until the invaſion of Philip. When the progreſs of Cyrus expoſed the Aſiatic colonies of Grecce to extreme danger, they in vain applied to Sparta for aſſiſtance; and, being ſoon conquered by the Perſian monarch, they remained in ſubjection, until the victories of Plateæ and Mycale reſtored them to freedom; but deſpairing of long maintaining their independence, they formed a ſtrict alliance with Athens, who availed herſelf of the opportunity of a general alarm, to propoſe an univerſal contribution from all her colonies and allies, for the great purpoſe of reſiſting the Perſian power. We might cite many other inſtances to exemplify the independence of the Grecian colonies on the ſtates from which they originated. Nevertheleſs, the benefits in point of civilization reſulting to barbarous countries from colonies of private adventurers, migrating

proof of the contrary doctrine, and the opinion of the Jews, however, reference has been made to the language of the Phariſees, when they objected to Chriſt's cure of dæmoniacs: "He caſteth out dæmons by Beelzebub (Gr. Beelzebul) the prince of dæmons." For the ſtatement and examination of this objection, ſee the article BEELZEBUB.

It has been ſaid, however, that the term dæmon bears a different meaning in the ſacred writings, from that which belonged to it in the profane; or, that our Saviour and his apoſtles uſed it in a ſenſe peculiar to themſelves. To this argument it has been replied, that as the ſacred writers have not particularly explained the ſenſe in which they uſe the word dæmon, we may naturally infer, that they uſe it in its common and ordinary ſignification; and that if they had aſſigned to it a new and peculiar meaning, we might have expected that they would have apprized us of it for the prevention of miſtakes. For the general ſenſe of theſe ages, concerning the ſubject under our preſent conſideration, we cannot refer to a more reſpectable authority than that of Juſtin Martyr, who was bred a heathen, and inſtructed in the principles of the heathen philoſophy; and who afterwards became a Chriſtian, and flouriſhed near the times of the apoſtles, or about the middle of the ſecond century. This learned writer affirms (Apol. l. i. al. 2. p. 65. Par. 1620), "That thoſe perſons who are ſeized and thrown down by the ſouls of the deceaſed, are ſuch as all men agree in calling dæmoniacs and mad." From the caſe of the poſſeſſed this father infers the permanency of the human ſoul after death; and yet he ſeems to have believed in dæmons of a different order from thoſe who were of the human ſpecies. Accordingly he calls the devil a dæmon (Cohort. ad Græc. p. 87. ed. Oxon.), and ſpeaks of the devil's deceiving our firſt parents. With regard to the language of the New Teſtament on this ſubject, it has been aſſerted that the evangeliſt John ſeems to intimate (ch. xiii. 2.) that the *devil* took poſſeſſion of Judas; whence it has been inferred that as this was the language of the vulgar, it ſhews that, in their eſtimation, Satan and his angels did occaſionally enter the bodies of men. In another place, (Acts, x. 38.) we read of perſons that were healed, "who were oppreſſed of the *devil*," or held in ſubjection to the devil: whence it has been concluded, that to be poſſeſſed of dæmons, for to perſons in this ſtate the apoſtle ſeems to refer, and to be held in ſubjection to Satan, were expreſſions of the ſame import in the eſtimation of the Jews. With reſpect to the teſtimony of Juſtin Martyr, an ingenious writer obſerves, that he is pleading the cauſe of Chriſtianity againſt the worſhippers of dæmons, and that he ſeems to be deſirous of placing the objects of their worſhip in the moſt humiliating and contemptible point of view: and therefore in the diſcuſſion of this queſtion, we ought to regard him as an advocate, and not as exerciſing the authority of a judge. Joſephus, ſays the ſame writer, was a Jew, who held the pagan ſyſtem in the ſame contempt with which it was regarded by the Chriſtians; and whilſt he availed himſelf of an opportunity for degrading the objects of pagan worſhip, his words may be ſuppoſed to intimate, not that the ſpirits of deceaſed perſons only entered the bodies of men, but that all thoſe ſpirits which, under the name of dæmons, were adored by the heathens, were merely the ſpirits of deceaſed perſons deified by ſuperſtition. Joſephus and Juſtin Martyr, as we have elſewhere obſerved, (ſee DÆMON) ſeem to favour the opinion that fallen angels ſometimes occupied the bodies of men; for, they mean by angels (Antiq. i. 4. Apolog. ii. 112.) the fallen angels, or thoſe who, in the New Teſtament, are called the devil and his angels. Hence it has been concluded, that the indwelling dæmons of the New Teſtament were fallen angels: and that Beelzebub and the dæmons comprehend the devil and his angels, as well as the ſpirits of wicked men deceaſed. It muſt be allowed, whatever may be the ſentiments which we may adopt on this ſubject, whether we ſuppoſe the devil and his angels to be real or fictitious beings; and however we may extend or limit, admit or deny, the reality of their power and agency, that poſſeſſions were actually aſcribed by many of the fathers, after the time of Juſtin Martyr, to fallen angels. For their conduct in this reſpect, Mr. Farmer endeavours to account by the following conſiderations. Several philoſophers taught that the heathen dæmons were evil ſpirits of a rank ſuperior to mankind; and that theſe dæmons perſonated the ſouls of the dead, gods, and genii, and procured themſelves to be worſhipped under their names. In this opinion many of the fathers had been educated, and others adopted it from an attachment to the principles of ſome of the learned Gentiles. Motives of policy might likewiſe lead them to repreſent poſſeſſing dæmons as ſpirits of a higher order than mankind. Thus, whilſt St. Chryſoſtom (De Lazaro Conc. 2. tom. i. p. 728.) admits, that dæmons in poſſeſſed perſons pretended, that they were the ſouls of ſuch and ſuch a monk, he aſſerts that the devil perſonated the ghoſts of thoſe who had ſuffered a violent death, and thus cauſed men to think, that they became dæmons, that he might deſtroy the honour of the martyrs. By ſuch repreſentations they not only preſerved the credit of the Chriſtian martyrs, but contributed to diſgrace paganiſm, whilſt they repreſented its gods as devils, who perſonated theſe gods, and paſſed under their names. This view of the pagan gods ſerved alſo to diſparage the prophecies and miracles aſcribed to them by their worſhippers, and the reality of which was too haſtily allowed by the fathers. Mr. Farmer cites a number of paſſages, from which he infers that the fathers doubted or diſbelieved the reality of poſſeſſions, though they aſſerted it in their popular diſcourſes.

In the tranſlation of the New Teſtament in vulgar uſe, we frequently read of perſons *having* or *being poſſeſſed by a devil* or *devils*, and of Chriſt's *caſting out devils*. But the Scripture never deſcribes more than one evil ſpirit by the word devil; and never, (ſays Mr. Farmer), repreſents, any perſons as poſſeſſed by the *devil*, or by *devils*, not even in a ſingle inſtance, notwithſtanding the great frequency with which the evangeliſts ſpeak on the ſubject of poſſeſſions. In all the inſtances in which the term devil occurs in the Engliſh tranſlation of the New Teſtament, the original word is *dæmons* (δαιμονες, δαιμονια, δαιμονιζομενοι) and not that from whence comes the Engliſh word *devil* (διαβολος.)

In deſcribing perſons poſſeſſed the word δαιμων occurs only three times in the New Teſtament; once in each of the three goſpels, Matthew, Mark, and Luke; and in theſe three places it refers to the ſame poſſeſſion, *viz.* that of the furious man in the country of the Gadarenes, who haunted the ſepulchres. There does not, however, ſeem to be any material difference in this appellation from that of the diminutive δαιμονιον, which is alſo uſed by Luke in relation to the ſame dæmoniac. This term δαιμονιον occurs above fifty times, in reference to poſſeſſions real or ſuppoſed, and δαιμονιζομαι thirteen times. Whereas, it has been ſaid, the word διαβολος, *devil*, is never applied to poſſeſſion. The paſſage in the Acts in which thoſe "oppreſſed by the devil" are mentioned, and which we have already cited, ought to have been excepted.

It has, indeed, been generally apprehended, that dæmons and their prince are the ſame ſpirits with the devil and his angels. To which purpoſe it has been alleged, that Satan and Beelzebub are names for the ſame perſon; for when Chriſt was reproached with caſting out dæmons by

the aſſiſtance of the prince of dæmons, he replied, "How can Satan caſt out Satan?" (Matth. xii. 26. Mark, iii. 26. Luke xi. 18.) If Satan, it is ſaid, who is conſidered as the ſame perſon with the devil, (Rev. ix. 12. compare Matt. iv. 1. with Mark, i. 12.) was the prince of thoſe dæmons who were caſt out by Chriſt, then dæmons are the ſame ſpirits as the devil's angels. On this ſuppoſition there can be no other difference between dæmons and the devil, than that which ſubſiſts between a prince and his ſubjects, who both partake of one common nature, though the prince, as preſiding over the reſt, hath a peculiar name of his own. To this objection Dr. Sykes, who maintained that dæmons and their prince were a different order of ſpirits from the devil and his angels, never replied: and Dr. Lardner ſeems to admit its force; for he ſays, (Caſe of the Dæmoniacs, &c. Works, vol. i. p. 448.) "The devil is often called Satan and Beelzebub." For an abſtract of Mr. Farmer's reaſoning on this ſubject, ſee the article BEELZEBUB. See alſo DEVIL and SATAN.

Whether there ever were any real dæmoniacs, is a queſtion that will be conſidered under the article DÆMONIACAL *Poſſeſſion*.

In the Romiſh church, there is a particular office for the exorciſm of dæmoniacs.

DÆMONIACS are alſo a party or branch of the Anabaptiſts, whoſe diſtinguiſhing tenet it is, that the devils ſhall be ſaved at the end of the world.

DÆMONIACAL POSSESSION. Whether we allow that reputed dæmoniacs were really poſſeſſed by dæmons or not, it muſt be acknowledged that they are ranked in the New Teſtament amongſt thoſe who ſuffered the moſt grievous diſtempers. (See Matt. iv. 24. viii. 16, 17.) Hence it may be inferred, that poſſeſſions are comprehended under infirmities and ſickneſſes; and if they had not been included under diſeaſes, the mention of them would not have been omitted in Matt. xi. 5; conſequently, poſſeſſions imply ſome diſorder or diſtemper in the human frame, from whatever cauſe it might proceed. It muſt alſo be admitted, that the miracle, wrought upon the demoniacs, of the reality of which there can be no doubt, is often deſcribed in the ſame terms as that wrought upon the diſeaſed; and theſe terms are ſuch as neceſſarily imply their having previouſly laboured under a real diſtemper, (ſee Matt. iv. 24. viii. 16, 17. xv. 28. xvii. 16, 18. Luke, vi. 18. vii. 21. viii. 2. ix. 42. Acts, v. 16.) Whenever a miracle wrought upon a dæmoniac is deſcribed, the evangeliſt ſays indifferently, Chriſt expelled the dæmon, or that he healed the dæmoniac; ſo that a real diſorder was cured, whenever Chriſt is repreſented as ejecting a dæmon. Amongſt the Greeks and Romans alſo, as well as amongſt the Jews, thoſe perſons who were thought to be poſſeſſed, ſuffered grievous diſtempers. Hence we may infer, that dæmoniacs were afflicted with certain diſtempers, whether the poſſeſſion of dæmons was the real or reputed cauſe of them. Moreover, an opinion ſeems to have very generally prevailed, both amongſt the Heathens and the Jews, that evil ſpirits or dæmons, (whether fallen angels or ſouls of bad men) were the inſtruments or authors of many afflictions and calamities to mankind. Madneſs, or diſtraction, is one evil often aſcribed to them. Forms of ſpeech to this purpoſe were very common. The nations bordering upon Judæa, as well as others, join inſanity and poſſeſſion together. In the plays of Æſchylus, of Sophocles, of Euripides, and of Plautus, from which we may judge what opinions prevailed in common life, thoſe who are ſpoken of as poſſeſſed are all either madmen, or perſonate ſuch. Beſides madneſs, the ancients alſo aſcribed epilepſy to poſſeſſion; eſteeming this diſorder ſacred on account of the entrance of dæmons into the bodies of thoſe who ſuffered under it. Mr. Farmer is of opinion that all the dæmoniacs ſpoken of in the New Teſtament were either madmen or epileptics. Poſſeſſion, he ſays, referring to John, x. 20, 21, may be conſidered as the cauſe, and madneſs as the ſuppoſed effect; or madneſs was the evidence of poſſeſſion.

The language of this paſſage is obviouſly grounded on the connection ſuppoſed to ſubſiſt between poſſeſſion and inſanity. (See alſo John viii. 48, 49. 51, 52. vii. 20.) Melancholy, as well as raving madneſs, was aſcribed by the Jews to dæmons. (See Matt. xviii. 11. Luke vii. 33. See alſo the account of the Gadarene dæmoniacs in Matt. viii. 28. Mark v. 2. Luke viii. 27.) With regard to epileptics, it is obſerved by the ſame writer, that if their diſtemper was by the ancients aſcribed to poſſeſſion, it was becauſe it was attended with a deprivation of the underſtanding, or loſs of ſenſe, and with the ſigns of phrenſy. (See Matt. xvii. 25. Mark ix. 18. Luke ix. 33.) On the other hand, Dr. Lardner contends, "that all thoſe ſaid to have evil ſpirits were not diſcompoſed in their minds," in proof of which he refers to the caſe of the epileptic youth above-mentioned, that recorded in Mark i. 23. 26. Luke iv. 33., and the two inſtances mentioned by St. Matthew (ix. 32.) and Matt. xii. 22. Luke xi. 14. In ſupport of his hypotheſis he alſo appeals to paralytic caſes; whereas Mr. Farmer maintains that paralytics are never ſpoken of in the goſpel as dæmoniacs; and that the goſpel expreſsly diſtinguiſhes palſies from poſſeſſions. (Matt. iv. 24.) With regard to two other paſſages, cited by Dr. Lardner, in one of which a woman is ſpoken of whom "Satan bound" (Luke xiii. 11. 16.), and in the other all diſeaſed perſons are deſcribed as "oppreſſed by the devil" (Acts x. 38), Mr. F. obſerves, that a diſtinction ſhould be made between diſorders which the Jews conſidered as *inflicted* by evil ſpirits, and ſuch as they aſcribed to evil ſpirits *poſſeſſing* mankind. Epileptics, it is ſaid, were by the Greeks and Latins called lunatics; but the evangeliſts, as well as the ancients, diſtinguiſhed between dæmoniacs and lunatics, the former being maniacs, and the latter epileptics, the fits of whoſe diſeaſes were ſuppoſed conſtantly to return with every new and full moon. Accordingly Galen ſays, "the moon governs the periods of epileptic caſes." However, many reputed the ſame perſon to be both a dæmoniac and a lunatic; a dæmoniac, becauſe they referred the epilepſy to the poſſeſſion of dæmons, and a lunatic, becauſe the fits of this diſorder were thought to keep lunar periods. While ſome aſſerted the natural influence of the moon upon this diſorder; others taught, that the patients were more ſubject to the incurſions of dæmons at the changes of this planet than at any other time. Such, perhaps, was the caſe of the youth deſcribed in the goſpel; for his father repreſents him both as lunatic and ſore vexed with a dæmon; or he might have been what ſome modern phyſicians call "epileptic mad." (Mead, p. 46, 47.) The ancient Chriſtian writers are ſaid to deſcribe dæmoniacs as perſons diſordered in their mind; and conſidered them as mad, melancholy, or epileptic perſons. (See Mr. Joſ. Mede, p. 30. Wetſtein, vol. i. p. 283.)

Some writers have aſſerted, that there were no dæmoniacs, whether poſſeſſions be ſuppoſed to be real or imaginary, or not ſo many amongſt any other people as the Jews; nor amongſt them, but about our Saviour's time. Hence unbelievers have taken occaſion to triumph; and have conceived unfounded prejudices againſt the goſpel, repreſenting it as ſomewhat extraordinary, that the devil ſhould exert his power at the appearance of his judge and avenger, rather than at any other time, when he might do it with greater hopes of impunity; and contumelioufly aſking, whether or not we can regard

Chriſt as the Saviour of mankind, if he gave the devil new powers to deſtroy them? In accounting for this ſuppoſed fact, they have ſuggeſted a variety of arguments. A greater liberty and power, ſay ſome of them, might be allowed the evil ſpirits, in the age of Chriſt than in any other, on account of "the intimate relation that dæmoniacal poſſeſſions have to the doctrine of redemption." (Warburton's Serm. vol. iii. p. 229.) The biſhop alſo (p. 217.) concurs with Dr. Macknight, (Truth of the Goſpel Hiſtory, p. 169.) Stillingfleet (Orig. Sacr. p. 166.), in alleging other weighty reaſons for this fact, ſuch as the glory that accrued to God, and the teſtimony that was borne to Jeſus, when Satan was caſt out by a divine power. The learned Stillingfleet, indeed, is at a loſs to determine, whether frequent poſſeſſions, at and after the time of Chriſt, were owing to the malice of the devil, in order to *diſparage* the miracles of our Saviour, or to the providence of God, in order to *augment* his glory. Dr. Jortin thought that Providence ſuffered evil ſpirits to exert their malignant powers ſo much at that time to give a check to Sadduceiſm among the Jews, and to Epicurean atheiſm among the Gentiles. (Rem. on Eccl. Hiſt. vol. i. p. 14.) In another place (vol. ii. p. 17, 18.) he ſays, that Chriſt cured poſſeſſed perſons, in order to ſhew that he came to deſtroy the empire of Satan, and to remove all ſuſpicion of a confederacy with evil ſpirits. Theſe ſpirits, ſays biſhop Newton (Works, vol. iv. p. 302.), had at the time of our Saviour's appearance a particular reaſon for exerting their power and malice, in oppoſition to the firſt erection and eſtabliſhment of the kingdom of God; and they might be permitted to exert them to the utmoſt, in order more effectually to diſplay the ſuperior power and goodneſs of him whom God had ſent into the world, to render their defeat more conſpicuous, and to gain the greater credit to him and his diſciples. But it has been ſaid, that this reaſoning accounts for a fact, *viz.* God's permitting or forcing the devil to take poſſeſſion of men's bodies at the time of Chriſt, and at no other, which has no foundation to ſupport it. It ſhould be conſidered, however, that, many ages before the birth of Chriſt, and in other countries beſides Judæa, men aſcribed their diſeaſes in general to ſpirits. The account of dæmoniacs occurs, as we have already ſhewn, in the writings of more ancient and later dramatic poets, of hiſtorians, of phyſicians, and of philoſophers. The eſtabliſhed theology of the heathen world, from its firſt riſe to its final overthrow, reſted upon the baſis of dæmoniſm. With regard to the Jews, Joſephus informs us (Antiq. l. viii. c. 2. § 5.), that the method of exorciſm preſcribed by Solomon, "prevailed or ſucceeded greatly among them down to his time." The very exiſtence of exorciſts, both before and after the time of Chriſt, and the general prevalence of magic arts among this people, as well as among the Gentiles, are a full proof that a belief of frequent poſſeſſions was common to both; and, indeed, the ſcripture itſelf furniſhes abundant evidence, that the doctrine of poſſeſſions was prior to the Chriſtian era. (See Matt. xv. 21, 22. xvii. 15. Mark vii. 24. ix. 17. Luke ix. 39. Acts xvi. 16, 18. xix. 3.) It is obſervable, that the enemies of Chriſt never reproach him with introducing dæmons into Judæa, where they were not new or extraordinary, and occaſioned no ſurpriſe, merely for the ſake of diſplaying his power over them; nor on this account accuſe him of acting in concert with them, which, nevertheleſs, it would have been natural for them to do, if poſſeſſions had never been heard of till the time of Chriſt, and then only in Judæa. Some perſons have aſſerted, that the devil's tyranny expired, which is contradicted by numberleſs facts of real or ſuppoſed poſſeſſions, as well as revived, at the coming of Chriſt. Moreover, the dæmoniacs of the New Teſtament are the ſame ſort of perſons with thoſe mentioned in other writings, and, therefore, it is reaſonable to aſcribe the diſorders expreſſed by them, or pertaining to them, to the ſame or ſimilar cauſes.

Thoſe who deny the *reality* of poſſeſſions argue, that in the ages of ignorance and ſuperſtition, the credulous part of mankind were eaſily perſuaded to believe, that maniacs and epileptics were really poſſeſſed by dæmons; but that thoſe who conſulted their reaſon, and gained an inſight into nature, pronounced what commonly paſſed for dæmoniacal poſſeſſions, to be mere natural diſorders. The divine Hippocrates wrote his book, Περι Ἱερης Νοσου, to ſhew, that the epilepſy has nothing in it ſupernatural, more than any other diſtemper; and to expoſe the ignorance and impiety of thoſe who aſcribed it to the immediate agency of the gods, and accordingly undertook to cure it by expiations and charms. Amongſt many other conſiderations which he has urged to prove that epileptical diſtempers owe their riſe to natural cauſes, he obſerves, (De Morbo Sacro, p. 307. ed. Foeſii) "that goats are remarkably ſubject to the epilepſy; and, on diſſecting the head, the brain is found to be overcharged with a rheum of a very bad ſmell, a plain proof, he adds, that the animal is diſeaſed, not poſſeſſed by a deity."

Celſus (lib. iii. c. 18.) when treating of the ſeveral kinds of madneſs, takes no notice of dæmoniacal poſſeſſion, and aſcribes them to different cauſes. Plotinus, a Platonic philoſopher of the third century, ſpeaks of thoſe who pretended to cure diſorders by expelling dæmons, "as admired only by the vulgar," while they were deſpiſed by men of ſenſe, who believed, "that all diſeaſes proceed from natural cauſes." We learn from Origen (in Matt. tom. xiii. vol. i. p. 311. Huet. vol. iii. p. 577. Bened.) that phyſicians, in his time, accounted in a natural way for diſorders imputed to dæmons, though he condemned them for ſo doing. Many other inſtances might be mentioned to the ſame purpoſe. Dr. Mead (Med. Sacr. c. ix. p. 66, 67.) alleges, that the circumſtances related of the goſpel dæmoniacs are ſymptoms of natural diſorders, and do not exceed the powers of phyſical cauſes. It has been further argued, that as the ſeveral diſorders, imputed to poſſeſſion, proceed from natural cauſes, they alſo yield to natural remedies, and each of them requires a peculiar proceſs. It has alſo been urged, particularly by Mr. Farmer, that the human ſyſtem, like that of nature in general, is ſubject to invariable laws, ſuch as no being but God can controul. Indeed, he ſays, the doctrine of dæmoniacal poſſeſſions is ſo manifeſtly repugnant to the perfections of God, to the wiſdom, equity, and goodneſs of the divine government, and to that fixed order of cauſes and effects which we diſcover in every part of nature, and particularly in the human ſyſtem, that few perhaps in this enlightened age would appear in its defence, were it not from an apprehenſion that it is ſupported by the authority of revelation. He alleges, however, that whether the doctrine of poſſeſſion be true or falſe, it was not originally founded on revelation; and that it never received the ſanction of any of the prophets of the Old or New Teſtament.

The Old Teſtament, it is ſaid, is ſilent on the ſubject of poſſeſſions, and cannot be employed to eſtabliſh their reality. When Saul is ſaid to be "troubled by an evil ſpirit from the Lord" (1 Sam. xvi. 14. xviii. 10.), it is ſufficient to obſerve, that the word ſpirit is often uſed to denote the temper and affections of the human mind, and that the Jews were accuſtomed to call all kinds of melancholy an evil ſpirit. Accordingly, Saul's diſorder was a deep melancholy; and it was cured by muſic. As to the writers of the New Teſtament, they were not the original authors of the doctrine of poſſeſſions. In Chaldæa, Egypt, Greece, and all other countries,

tries, the doctrine of dæmons generally prevailed from the earlieſt ages. From the Gentiles it was tranſmitted to the Jews, not at Babylon only, but in every other place of their diſperſion, and even in Judæa itſelf. But though this doctrine be not a diſcovery of revelation, it has been ſaid, that various expreſſions uſed by Chriſt and his apoſtles are thought by ſome to aſſert or imply the reality of poſſeſſions. We are told, that the people brought to Jeſus were ſuch as were *poſſeſſed and vexed with unclean* ſpirits; and that he *caſt out ſpirits with his word*. But perhaps theſe learned writers do not ſufficiently conſider, that the reality of poſſeſſions and diſpoſſeſſions was never taught by Chriſt and his apoſtles as a doctrine; and that they could not, with propriety, interpoſe their authority in eſtabliſhing the reality of poſſeſſions, conſidered as the ſecret cauſe of thoſe diſorders imputed to them; for the miraculous cure of theſe diſorders being a part of that evidence which was aſſigned for the conviction of unbelievers, we are to judge of the nature of the miracle in queſtion by reaſon alone, not by an authority which cannot be admitted previous to its performance. Beſides, as poſſeſſion by dæmons was anciently thought to produce ſome maniacal diſorder; and the expulſion or departure of dæmons was thought to effect a removal of the diſorder, or a recovery of the underſtanding; it hence came to paſs that poſſeſſions and diſpoſſeſſions were in common life uſed to expreſs thoſe outward and ſenſible ſymptoms they were thought to produce, or the *diſorder* and *cure* of reputed dæmoniacs. It is very common to give to an effect the name of the cauſe to which it is aſcribed. And whenever the ſuppoſed cauſe or author of any thing is put for the thing itſelf, the cauſe or author is not included. When Ceres, for example, ſtands for corn, and Bacchus for wine; corn and wine alone are intended. In like manner dæmoniacal poſſeſſion was uſed merely to expreſs madneſs, without taking the cauſe into the account. Joſephus (Bell. Jud. lib. ii. cap. 13. ſect. 4.) ſays, concerning certain demagogues, that "they perſuaded the multitude to be poſſeſſed *by dæmons*," when his whole meaning was, "That the people were worked up into *a phrenſy* by the artifices and eloquence of their leaders." Thus, amongſt the moderns, *lunacy*, which at firſt denoted that peculiar kind of phrenſy over which the moon was ſuppoſed to have an influence, is now uſed for phrenſy in general. Nor are the evangeliſts to be blamed for deſcribing the diſorder and cure of dæmoniacs in the popular language, that is, by poſſeſſions and diſpoſſeſſions; inaſmuch as they might adopt the popular language on this ſubject (as they certainly have done on other ſubjects, and all other perſons daily do) without deſigning to eſtabliſh the doctrine on which it was originally founded.

So far, ſay the anti-dæmoniſts, is the Chriſtian revelation from aſſerting the reality of dæmoniacal poſſeſſions, or repreſenting it as a part of that doctrine which they were immediately inſtructed and commiſſioned by Heaven to publiſh and confirm, that this doctrine is contradicted by revelation. It is inconſiſtent, they ſay, with the fundamental principle both of the Jewiſh and Chriſtian diſpenſations, with the proper evidence of miracles in general, and with the nature of that miracle in particular, which was performed upon dæmoniacs. What is the grand principle of the Jewiſh and Chriſtian diſpenſations, but that Jehovah is the one true God, the ſole Creator and Sovereign of the world, which he governs by fixed laws? Do not the Old and the New Teſtaments concur in referring to the immediate and miraculous agency of God alone, all effects which are contrary to that courſe and order of events, which he has eſtabliſhed? If then there be no ſovereign of nature but God, and no mediator between God and man but Chriſt, there can be no other ſuperior intelligences, who have any power over the laws of nature, or over the human ſyſtem in particular. Beſides, all the prophets of God, in every age, when profeſſedly delivering their meſſages to mankind, have with one voice proclaimed the utter impotence of dæmons, and hereby intirely ſubverted the doctrine of dæmoniacal poſſeſſions. Whoever, it is ſaid, the heathen dæmons or deities were, whether human or angelic ſpirits, they are all, without exception, branded in Scripture as being utterly void of all power to do either good or evil to mankind. See DÆMON and IDOL.

Did we not conſider, ſays an ingenious writer on this ſubject, how far prejudice is capable of perverting the underſtanding, it muſt ſeem incredible, that Chriſtians ſhould form their judgment of the ſentiments of the ſacred writers concerning poſſeſſions by their deſcriptions of dæmoniacs, rather than by their profeſſed doctrine concerning dæmons. If what all the prophets of God, under both Teſtaments, have taught us concerning the utter inability of dæmons or heathen deities to do either good or harm to mankind; if this doctrine be true, there never was, nor can be, a real dæmoniac.

The advocates of the *reality* of poſſeſſions have urged a variety of arguments in favour of their opinion. Theſe we ſhall now, in as brief and conciſe a manner as is conſiſtent with juſtice and candour, recite. If there was no agency of evil ſpirits in the time of our Saviour, it has been aſked, how came this opinion ſo generally to prevail, and why ſhould many perſons have thought themſelves to be poſſeſſed by evil ſpirits? To this argument it has been replied, that this is not the only inſtance in which unfounded notions have been very prevalent; and that the influence of dæmons in occaſioning mental and bodily diſorders had been acknowledged for a long time before our Saviour's appearance in the world. But notions of this kind had chiefly prevailed amongſt the vulgar and leaſt informed, and had been exploded, as groundleſs and fallacious, by perſons of ſuperior wiſdom, reflection, and experience. However, whilſt ſuch ſentiments prevailed, it was not unlikely, that ſome perſons, who were afflicted with grievous diſtempers, ſhould think themſelves haraſſed and tormented by evil ſpirits, and occaſionally ſpeak in conformity to their inward apprehenſions.

An appeal has been made to what is reported to have been ſaid and done by the dæmoniacs themſelves. Hence it has been concluded, that they were inſpired and aſſiſted by ſuperior agents, ſuch as dæmons are commonly ſuppoſed to be. Accordingly, it is pleaded, that the dæmoniacs knew, and proclaimed Jeſus to be the Meſſiah. (Luke, iv. 34. 41. Mark, i. 24. Matth. vii. 29.) How, it is ſaid, ſhould theſe perſons know Jeſus to be the Chriſt, if they were not under the influence of evil ſpirits of great knowledge as well as much power? Theſe dæmoniacs, it is ſaid, who were either epileptics or maniacs, with occaſional intervals of ſanity, had the ſame means of knowing Jeſus to be the Chriſt which others poſſeſſed. He was the object of univerſal attention; his fame had been propagated throughout all Judæa and the adjacent countries, and had excited a general perſuaſion that he was the Meſſiah. The dæmoniacs, before they were ſeized with their diſorder, and in their intervals of ſanity, might hear of the fame of Jeſus as the expected Meſſiah, for they had many opportunities for this purpoſe; and it is ſuggeſted, that they might adopt the common opinion concerning his character as the promiſed Meſſiah, and declare that opinion more eagerly than perſons of a cooler judgment: and this ſeems to be more probable, it is ſaid, than that infernal ſpirits ſhould freely and zealouſly aſſert the divine claims, and ſpread the glory of Jeſus as the Meſſiah.

Meſſiah. It has been further urged in ſupport of the reality of poſſeſſions, that Chriſt commanded the "devils (dæmons) not to diſcover him." (Mark, i. 23. 26. 34. iii. 12. Luke, iv. 33, 34, 35, 41.) To this argument it has been replied, that dæmoniacs were not only regarded by others, but generally conceived of themſelves, as ſpeaking and acting under the influence of the ſpirits by which they believed themſelves to be poſſeſſed, or as being thoſe very ſpirits. Hence the dæmon and dæmoniac were often confounded together; both being deſcribed under the ſame term, and the ſame act being referred indifferently to either. (See DÆMONIAC.) When the evangeliſts, therefore, tell us, "that Jeſus ſuffered not the *dæmons* to ſay, that they knew him to be the Meſſiah," they are to be underſtood of the *men* poſſeſſed by them. The ſame prohibition which he gave to the multitude, and to his own diſciples, he gave to them; becauſe their confident perſuaſion of his being the Meſſiah, and their gratitude to him for this miraculous relief, would prompt them to proclaim the high and honourable opinion which they entertained concerning him; and leſs guarded than others in their language and conduct, they would be more diſpoſed to publiſh their ſentiments. By checking their zeal, he might alſo wiſh to prevent any ſpecious pretence on the part of his enemies, that there was a ſecret agreement between him and thoſe evil ſpirits, who were judged to be ſo eager in applauding him. Some again have ſaid, that dæmoniacs could not be mere madmen, becauſe they argue with Chriſt in a very rational manner, and ſpeak to better purpoſe than the bulk of thoſe who were in their ſenſes. This aſſertion is chiefly founded upon the behaviour of the Gadarene dæmoniac: (Matt. viii. 28. Mark, v. 2. Luke, viii. 27.); and many reaſons have been ſtated by Mr. Farmer (Eſſ. on Dæmon. p. 260, &c.) in order to prove, that it did not warrant the ſuppoſition of his being directed and aſſiſted by ſuperior intelligences in all that he ſaid and did; but that it appears to be that of a madman according to the expreſs repreſentation of him in the hiſtory. In favour of the reality of poſſeſſions, it has been further alleged, that dæmoniacs exerted more than human ſtrength. (Mark, v. 3, 4.) To which it has been replied, that perſons in ſimilar circumſtances have at ſome ſeaſon exhibited uncommon ſtrength, and that the ancients were leſs ſkilful than the moderns in the methods of confining ſuch unhappy perſons. Another argument in proof of real poſſeſſions has been deduced from the deſtruction of the herd of ſwine which the dæmons are ſaid to have entered, and to have ſtimulated to inſtantaneous madneſs; which caſe has been conſidered as a deciſive evidence of the power of dæmons, both over the human and brutal race, and ſuppoſed to have been purpoſely deſigned by Providence, to convince us of this principle, and to refute the oppoſite opinion. (Matth. viii. 30. Mark, v. 11. Luke, viii. 32.) On the other hand, it has been alleged by Dr. Sykes and Dr. Lardner, that the ſwine were frighted by the two madmen, and ſo driven down the precipice into the ſea. Mr. Farmer, diſapproving the account of this fact given by theſe writers, as well as by the advocates of real poſſeſſion, maintains, that the men, if we take the words of the evangeliſts for our guide, neither drove, nor attempted to drive, the herd into the ſea. The hiſtory, he ſays, aſcribes the deſtruction of the ſwine, not to their being driven by the dæmoniacs, but to the entrance of dæmons into them, or to their being ſeized with the ſame diſorder from which the men were relieved, and which was thought to be cauſed by dæmons. Diſallowing the agency of dæmons, however, he ſuppoſes that the madneſs of the men was transferred to the ſwine by the immediate agency of God. This miraculous deſtruction of the ſwine he conſiders as a juſt puniſhment of the owners, who were probably Jews, and who were prohibited by the laws of Hyrcanus from keeping ſwine, and by the law of Moſes from partaking of their fleſh as food; and in this view of it, the miracle itſelf performed by Chriſt under a divine commiſſion, ſerved to manifeſt his regard to the law of God. The deſtruction of the ſwine ſerved alſo to aſcertain the *reality*, and to ſpread the *fame* of the miracle wrought upon the dæmoniacs. It was alſo adapted for correcting the falſe notions, concerning the power of dæmons, which were entertained in that age, as well by Jews as Gentiles, by both of whom Gadara was inhabited. Beſides, this miracle prevented ſeveral great inconveniencies that would otherwiſe have attended the miniſtry of Chriſt: *e. g.* the loſs ſuſtained by the Gadarenes prevented both Jews and Gentiles in thoſe parts from applying to Chriſt merely for the temporal benefit of his miracles, which was not their proper object, and which could not be diſpenſed to the Gentiles without increaſing the prejudices of the Jews; the behaviour of the Gadarenes in intreating Chriſt to depart out of their coaſts, ſeems to ſhew how indiſpoſed they were at that time to receive the ſpiritual bleſſings of the goſpel, and thus vindicates our Saviour in declining all familiarity with them; and the miracle, performed at the period of our Lord's higheſt popularity, ſtruck an awe upon the minds of the Jews, and in ſo doing prevented their raiſing tumults in his favour, as they were inclined to do, and their following him merely from worldly motives. With regard to this miracle, it may be further obſerved, that, though the diſpenſation of the goſpel, as a diſpenſation of mercy, was confirmed chiefly by miracles of mercy, it was nevertheleſs neceſſary that there ſhould be ſome examples of ſeverity, to check preſumption, and to warn men of the danger of rejecting a prophet, who was eminently the meſſenger of God's love, but at the ſame time the appointed miniſter of his juſtice.

After all, the moſt popular, the moſt plauſible, and the moſt perſuaſive argument in favour of real poſſeſſions is deduced from the language of Chriſt and his apoſtles, in performing and recording the cure of dæmoniacs, or in deſcribing the caſe of theſe unhappy perſons. From ſeveral paſſages of the New Teſtament, in which the mention of dæmons or dæmoniacs occurs, it has been inferred, that our Saviour and his apoſtles entertained and countenanced the doctrine of real poſſeſſions. If it was an error, the inſpired teachers of the goſpel, it is ſaid, muſt have known it, and ought therefore to have rectified it, inſtead of knowingly confirming the people in the belief of it. "It is impoſſible for me," ſays Dr. Campbell, "to deny the exiſtence of poſſeſſing dæmons, without admitting that the ſacred hiſtorians were either deceived themſelves in regard to them, or intended to deceive their readers. Nay, if they were faithful hiſtorians, this reflection, I am afraid, will ſtrike ſtill deeper." It is allowed, on the other hand, that our Lord and his apoſtles did uſe the common language of the age and country in which they lived on the ſubject of dæmoniacs, and that this language was originally founded on the ſuppoſition of the reality of dæmoniacal poſſeſſions. But, it is ſaid, that by uſing this language, they did not give their ſanction to the opinion from which it took its riſe. As neither the opinion nor the language originated with Chriſt and his apoſtles, they incur blame, if this ſhould be the caſe, merely for not departing from accuſtomed modes of expreſſion on this ſubject, and recurring to the uſe of new language concerning it. As they never aſſert the doctrine of poſſeſſions, but are thought, by thoſe whoſe ſentiments we are now ſtating, to have taught doctrines that militate againſt and ſubvert it, they muſt contradict themſelves, if by uſing the

common

common language with reſpect to dæmoniacs, they intended to countenance the opinion on which it was firſt grounded.

But it is maintained, that merely from the manner in which they ſpeak of reputed dæmoniacs, none can juſtly infer, that they deſigned to aſſert the reality of dæmoniacal poſſeſſions. Dr. Sykes and many others have obſerved, in reference to this ſubject, that it is cuſtomary with all perſons, and with the ſacred writers in particular, and with our Saviour himſelf, to uſe the language of the vulgar, though known and admitted to have been originally grounded on a falſe philoſophy. This kind of condeſcenſion and accommodation has been cuſtomary in a variety of caſes, that occur in common life; and it would argue an indecorous affectation and pedantry to abandon ordinary modes of expreſſion, eſtabliſhed by long and general uſage. When the ſacred writers, therefore, adopt the vulgar phraſeology, though grounded on an erroneous hypotheſis, we are not warranted in concluding, merely from this circumſtance, that they give their ſanction to ſuch an hypotheſis, or that they make themſelves reſponſible for its truth or falſehood; any more than the naturaliſt does, when he adopts vulgar expreſſions, and ſays, "the dew falls," "the ſun riſes, ſets, runs his race, or is eclipſed." Why then, it is ſaid, might they not adopt the common language, with reſpect to poſſeſſion, conſidered as the cauſe of a bodily diſorder? Can you infer their belief of poſſeſſions from their ſaying, that ſome "had dæmons," or "a ſpirit of Apollo," any more than you can learn a man's ſyſtem of philoſophy, from his ſaying, that his friend hath "St. Anthony's fire," or from his affirming that the ſun "riſes" and "ſets" every day? Moreover, Jews and Heathens, and even the ancient prophets, when ſpeaking of poſſeſſions, or on ſimilar ſubjects, adopt the common phraſeology, when they did not intend to countenance the opinion on which it was originally grounded; why, it is ſaid, might not this be the caſe with regard to Chriſt and his apoſtles? It is allowed, that, in ſome caſes, our Saviour and his apoſtles do uſe ſuch expreſſions, even on the ſubject under conſideration, as they could not deſign to have underſtood in a literal ſenſe, or in their fulleſt import. Thus, when they ſay, that one perſon was poſſeſſed by "ſeven dæmons" (Luke, viii. 2.), and another by "a legion" (Mark, v. 15.), is it not more natural to ſuppoſe, that they adopted the phraſeology of the Jews, in the ſame general ſenſe, than that they determined, by the aid of inſpiration, the preciſe number of dæmons, by which each of them was poſſeſſed? It was a very common opinion among the Jews, though not peculiar to them, that evil ſpirits frequent deſolate places, and this opinion is alluded to in the New Teſtament, (ſee Matt. xii. 43. Luke, xi. 24. Rev. xviii. 2.); but ſhall we repreſent him, who poſſeſſed all the treaſures of wiſdom and knowledge, as entertaining and ſanctioning this vulgar notion, becauſe he alludes to it, for the purpoſe of uſeful inſtruction, in his addreſs to the Jews? When he ſays on one occaſion, "Come out, thou unclean ſpirit" (Mark, v. 8.), and on another, "Thou dumb and deaf ſpirit, I charge thee come out of him" (Mark, ix. 25.); ſhall we hence infer, that he believed ſpirits to be dumb, deaf, and unclean? In another place (Luke, x. 18.), our Lord cannot be underſtood literally, when he declares, "I beheld Satan as lightning fall from heaven;" by which expreſſion he informs us, that he had a prophetic view of the ſudden overthrow of ſuperſtition and idolatry, (uſually deſcribed as the kingdom of Satan, or an adverſary,) or of the ſpeedy prevalence of true religion over every "oppoſing power." Hence, and from ſimilar inſtances, it is inferred, that merely from their deſcribing dæmoniacs in the common popular language, we are not warranted in concluding certainly, that either Chriſt or his apoſtles entertained the opinion to which that language owed its riſe. Dr. Lardner is of opinion, that the evangeliſts, at the time of writing their hiſtories, believed real poſſeſſions; but Mr. Farmer obſerves, that this can no more be inferred concerning *them*, from their mode of recording, than it can be inferred concerning *Chriſt*, from his manner of performing, the cure of dæmoniacs. It is further added, that Chriſt and his apoſtles had ſufficient reaſon for adopting the common phraſeology with reſpect to dæmoniacs, (ſuppoſing that they did not approve the hypotheſis on which it was grounded,) becauſe it was employed to deſcribe the real caſe of theſe perſons, the ſymptoms of their diſorder, and their cure. If we advert to the manner in which Chriſt performed cures upon the dæmoniacs, when he commanded the dæmons to come out, theſe commands, it is ſaid, manifeſtly ſuppoſe, that the beings to whom they are addreſſed are capable of obeying them, and that Chriſt expected them to obey him from a conviction and awe of his divine authority. But to this it is replied, that it was no unuſual thing with our Saviour to addreſs the elements, and other objects equally inſenſible, as agents endowed with reaſon and liberty. To the dead Jeſus ſaid, "Ariſe." He "rebuked the winds and the ſea," (Matt. viii. 26.) ſaying, "Peace, be ſtill." (Mark, iv. 39.) And he "rebuked a fever, and it left" the patient. (Luke, iv. 39.)

It is alleged further, in anſwer to the objection above ſtated, that the firſt publiſhers of the goſpel do not appear to have had any warrant for changing the vulgar language, in deſcribing the caſe of dæmoniacs; or that they were divinely commiſſioned to inſtruct mankind in the ſecret cauſes of the diſtempers which they were empowered to cure, and to rectify any phyſical miſtakes concerning them; nor, indeed, could they be commiſſioned for this purpoſe: for the miracles wrought on the dæmoniacs were deſigned for the conviction of unbelievers; and therefore their nature was to be determined by the teſt of reaſon alone, *before* men believed, *i. e.* before they could admit the authority of their performers, or pay any deference to their judgment.

The oppoſers of the common hypotheſis concerning poſſeſſions have pleaded, in vindication of Chriſt and his apoſtles for always uſing language conformable to that hypotheſis, that the prejudices of mankind in favour of the power of dæmons were very ſtrong, and almoſt invincible; and that if they had begun with an attack upon theſe prejudices, it would have prevented the converſion of multitudes, and led them to conceive of the firſt publiſhers of the goſpel as infidels and Sadducees. And it ſhould chiefly be conſidered, that their inſtructions did not directly extend to this caſe, nor could properly extend to it; the cure of dæmoniacs being a part of that evidence of the goſpel, which muſt for ever be judged of by reaſon alone.

The advocates of real poſſeſſions have further urged a conſideration of great moment, even in the eſtimation of ſome perſons who have adopted the contrary hypotheſis; and this is, that if their opinion be an error, Chriſt and his apoſtles ought to have corrected it; becauſe it was a very *dangerous* error, and the ſupport of much ſuperſtition and idolatry. This mode of reaſoning, it is argued on the other hand, indicates great preſumption, and ſeems to preſcribe to the wiſdom of God what he ought to do, and what kind and degree of inſtruction and evidence he ought to afford for correcting error, and promoting the belief of the truth. It is ſaid, however, that the firſt publiſhers of the goſpel have, in the moſt proper manner, rectified the dangerous errors that prevailed with regard to dæmons, and in ſo doing ſufficiently ſecured the intereſts of true piety. This they have done

done by their doctrine and by their miracles. As many idolatrous and ſuperſtitious practices have been grounded on a belief of the power of dæmons, the prophets of God under the New Teſtament, as well as thoſe under the Old, have openly taught, what their miracles intimated, the utter inability of theſe ſpirits to do any good or evil to mankind. Biſhop Warburton, and ſome others, have ſuggeſted, that an explicit declaration of Jeſus or his apoſtles concerning poſſeſſions would have neceſſarily determined the judgment of Chriſtians. But, ſuch was the power of prejudice, and ſo rooted the error which prevailed, that a declaration of this kind might have been as ineffectual as it was improper. They have done, however, more than this; they have repreſented all dæmons without diſtinction as mere fictions of the human imagination, and demonſtrated their nullity, and their total inability to produce any ſingle effect. In rectifying the miſtaken conceptions of mankind concerning dæmons, they have contributed to deſtroy, not one error only, but the whole fabric of Gentile idolatry and ſuperſtition. This was an object which their commiſſion comprehended, and indeed was one principal intention of it. This was one end for which our Saviour appeared in the world. This was one of the diſtinguiſhing characteriſtics that pertained to him as the Meſſiah. He was announced previouſly to his advent, and he was expected by the Jews, as the deſtroyer of dæmons; and ſo deciſive was this evidence of his divine miſſion, and of its grand object, that he himſelf appeals to it, and reaſons from it in proof of his being a divine Meſſenger and Saviour. "If I caſt out dæmons (ſays he) by the Spirit of God, then is the kingdom of God come unto you" (Matt. xii. 28.); *i. e.* If I reſtore dæmoniacs to their right mind by a divine power, the kingdom of the Meſſiah is certainly erected amongſt you. Not ſatisfying himſelf with verbally denying the power of dæmons, he declares it to have been the deſign, he adduces it as an evidence, of his miſſion from God, that he ſhould actually expoſe their impotence, and evince to mankind the folly of thoſe apprehenſions which were entertained concerning them. The ejection of dæmons, truly explained, affords one of thoſe auguſt diſplays and convincing proofs of the character of Chriſt as a Meſſiah and Redeemer, which were deſigned to recommend him to the veneration of mankind in all ages of the world.

DÆMONOLOGY. See DÆMON and IDOLATRY.

DÆMONOMANIA, in the *Pathology* of the older phyſicians, ſignifies that ſpecies of inſanity or delirium, whether real or pretended, which was attributed to the agency of the devil, or of dæmons, on the bodies of the individuals ſuppoſed to be poſſeſſed, or to hold communication with them.

It is unneceſſary, at the preſent day, to enter into arguments, with a view to confute the opinions that prevailed, in the ages of ignorance and ſuperſtition, reſpecting the effects and phenomena of dæmonical poſſeſſion. See DÆMONIAC. It muſt now be generally allowed, that all thoſe phenomena are explicable upon more obvious and ſatisfactory principles: and our wonder is excited, when we obſerve the minds of ſuch enlightened men, as Frederic Hoffmann, ſo far influenced by the vulgar prejudices of his age, as to contend for the reality of ſuch poſſeſſions, and to conſider the following circumſtances as proofs of their actual occurrence, namely, horrible noiſes, indecent geſticulations, and other unuſual corporeal motions, as well as convulſions without any previous diſeaſe, blaſphemous and obſcene language, predictions of future events; the knowledge of foreign tongues; extraordinary ſtrength, &c. (See Sauvage's Noſol. Method.) All theſe may be accounted for by a conſideration of phyſical and moral cauſes, of ordinary occurrence: and, therefore, we cannot but refer the different ſpecies of dæmonomania, deſcribed by noſologiſts, to one or other of the following ſources:

Firſt, they are inſtances of true inſanity, either mania or melancholy, or of the temporary delirium of intoxication. Such are the dæmonomania *fanatica* and dæmonomania *indica*, the fifth and ſeventh ſpecies of Sauvages. Noſol. Method. claſs viii. gen. 21. The hiſtory of fanaticiſm affords but too ample proofs of the madneſs of thoſe who have unhappily fallen under its influence. See FANATIC. Sauvages mentions a ſet of fanatics, who believed that the artillery, by which they were inhumanly ſlain in crowds, would, in conſequence of their religious zeal, play upon them with impunity. The dæmonomania *indica* is a temporary inſanity, induced by the uſe of an intoxicating herb, under the influence of which the Malays, in the iſland of Ceylon, run furiouſly through the ſtreets, armed with daggers, and ſtab indiſcriminately whomſoever they meet, crying, *amok*, or *kill*; whence this maniacal paroxyſm is termed by Europeans, "running a muck." See CEYLON.

Secondly, theſe ſuppoſed caſes of dæmoniacal poſſeſſion were, in other inſtances, the reſults of certain diſeaſes, falſely attributed by the by-ſtanders to the power of dæmons. Thus various convulſive ſymptoms, triſmus, and tetanus, diſtortions of the body, ſcreamings, delirium, &c. originating obviouſly from irritations in the bowels, or ſkin, or in the ſcalp, as from ſuppreſſed *plica polonica*, (Sauvages, ſp. 8. alſo ſp. 4. 6. and 9.) and ceaſing with the removal of thoſe irritations by cathartics, emetics, and other means, have been enumerated among the examples of dæmoniacal poſſeſſion, and attributed to the charms and incantations of witchcraft.

But, thirdly, other inſtances of dæmonomania, and thoſe amounting to no ſmall number of the recorded examples, were decidedly deceptions; the tricks of deſigning perſons, practiſing upon the credulity and ſuperſtition of the multitude. Such are the three firſt ſpecies of Sauvages: dæmonomania *ſagarum*, dæmonomania *vampiriſmus*, and dæmonomania *ſimulata*. The opinion that certain perſons, by a compact with dæmons, have obtained great powers over the lives and conditions of the reſt of the world, and the conſequent ſenſations, dreams and diſorders, ſuppoſed to be thus produced, has been propagated among the ignorant and credulous, and in darker ages even among the comparatively enlightened portion of mankind, in ſeveral ways. Theſe potent perſonages have, in ſome inſtances, effected their purpoſes, by exciting ſtrong impreſſions on the mind; the influence of which on the body cannot be queſtioned, by thoſe who are acquainted with the proceeding of the animal magnetizers, or the tractorizers, where the powerful aid of ſuperſtition was leſs employed. They have, at other times, employed certain narcotic drugs, which produce a great derangement of the nervous ſyſtem, a temporary delirium, much dreaming, or a pleaſurable ſort of intoxication, when the operation of the excited imagination itſelf, as well as of the wizzard upon it, was attributed to the power of his diabolical agency. In later times, the Meſmers and De Mainuducs have employed the former means of deranging the animal economy, *viz.* by exciting ſtrong impreſſions on the mind, without any pretenſions to diabolical powers; and dæmonomania, therefore, though not in fact, is by name, an obſolete diſeaſe. See Cullen Noſol. Method. gen. 66.

DÆRSTETTEN, or DARSTETTEN, in *Geography*, a ſmall town of Switzerland, or, as it is now ſtyled, of the Helvetic republic, ſituated in the canton of Berne in the diſtrict of Wimmis. It had anciently a celebrated monaſtery of

of Auguſtines, which in 1486 was incorporated with a monaſtery of the ſame order at Berne.

DÆSION, in *Chronology*, the Macedonian name for the Athenian month Antheſterion, which was the ſixth of their year, and anſwered to the latter part of our November, and beginning of December. See MONTH.

DÆSITIATÆ, in *Ancient Geography*, the name of a people placed by Strabo in Pannonia, and by Pliny in Dalmatia, whoſe chief was Baton or Bato.

DAFAR, DOFAR, or *Dolfar*, in *Geography*, a ſea-port town of Arabia Felix, in the province of Hadramaut, on the weſt coaſt of a bay in the Arabian ſea, to which it gives name, governed by a ſcheik, who is a ſovereign prince, and diſtant 160 miles E. N. E. from cape Fartach. The chief export from this town is the incenſe called olibanum, which is much inferior in quality and value to that of India.

DAFFNI, in *Biography*, an ancient architect, who, together with Peonius of Epheſus, fabricated the temple of Apollo at Miletus, a marble building of the Ionic order, and celebrated for its beauty and magnificence. Milizia Mem. degli Architetti.

DAFFODIL, in *Botany*. See NARCISSUS.

DAFFODIL, in *Gardening*, is a plant of the bulbous rooted flowery ornamental kind, for the borders, clumps, and other parts of pleaſure grounds. See NARCISSUS.

DAFFODIL, *Lily*. See AMARYLLIS and PANCRATIUM.

DAFFODIL, *Sea*. See PANCRATIUM.

DAFNE, in *Geography*, a river of European Turkey, in Bulgaria, which runs into the Urana between Marcenopoli and Varna.

DAFNE, in *Muſic*, the firſt melodrama, after the invention of recitative, that was performed to this new kind of narrative muſic. It was written by Rinuccini, author of the firſt great opera, Euridice, and ſet by Jacopo Peri and Giulio Caccini, and privately performed at Florence in 1600, previous to the public performance of Euridice, the firſt regular opera that was exhibited on a public ſtage in Italy, on the nuptials of Henry IV. of France with Mary of Medicis.

DAG, in *Agriculture*, a term ſignifying the dew hanging upon the graſs. It is chiefly applied when it remains long in the mornings upon the graſs-lands.

DAGANA, in *Ancient Geography*, *Thana-war*, a maritime town in the ſouthern part of the iſland of Taprobana, which, according to Ptolemy, was conſecrated to the moon.

D'AGAR, JACQUES, in *Biography*, a painter born at Paris in the year 1640. He became the diſciple of Ferdinand Vouet, and acquired under that maſter ſome ſkill in hiſtory-painting.

He however principally confined himſelf to portrait, and attained ſuch reputation that he was invited to the court of Denmark, where he enjoyed the favour of Chriſtian V. and of his ſucceſſor Frederick IV. He reſided ſome time in London, from whence he returned with conſiderable wealth to Copenhagen, and there died in 1716.

D'Agar deſigned with conſiderable elegance, and his tone of colouring is pleaſing and lively. His own portrait by himſelf is in the gallery of eminent painters at Florence. Pilkington.

DAGEBULLER KOEG, in *Geography*, a conſiderable tract of land, gained from the ſea in that part of Denmark which is called the duchy of Sleſwick, belonging to the Prefecture of Tundern in the iſland of Fohr. See KOEG.

DAGELET, a name given by Perouſe to an iſland about 20 leagues diſtant from the coaſt of Corea, from the aſtronomer who firſt diſcovered it. It ſcarcely exceeds three leagues in circumference, is very ſteep, and covered from its ſummit to the water's edge with the fineſt trees. A rampart of bare rock almoſt as perpendicular as a wall entirely ſurrounds it, with the exception of ſeven ſmall ſandy creeks where it is poſſible to land. On this iſland are ſome huts, which neither formed a village nor were ſurrounded by any appearance of cultivation. Hence it is probable that the ſhipwrights of Corea came hither in ſummer with their proviſions, to build boats, which they ſell upon the continent. In the creeks of the iſland ſeveral boats were obſerved upon the ſtocks, conſtructed exactly on the Chineſe model. The N. E. point of the iſland lies on N. lat. 37° 25′. and E. long. 129° 2′. from Paris.

DAGENHAM, a village of Eſſex, in England, on the banks of the river Thames, is remarkable for a ſingular inundation, which happened near it in the winter of the year 1707. By an unuſual ſwell of tide, and a violent wind ſetting up the river with it, a moſt deſtructive *breach* was made in its banks. A ſmall ſluice had been made for draining the land-floods, which being neglected, on the firſt aſſault of the tides, blew up; by which an opening was formed in places 20 feet deep, and 300 feet wide. Through this extenſive channel the influx of waters was ſo great, that upwards of 1000 acres of rich land were overflowed on the levels of Havermy and Dagenham; and the valuable ſoil of nearly 120 acres was carried into the Thames: by which a large ſand-bank was formed, reaching almoſt half way acroſs the river. The danger thence ariſing to its navigation occaſioned an application to parliament for aid to effectually repair the breach, and a ſmall tax was laid on veſſels entering the port of London for defraying the expence. After an ineffectual attempt had been made under the direction of Mr. Boſwell, a contract was entered into with captain Perry, who had been employed under the czar Peter in erecting the city of Veronitz on the river Don. The work was commenced under this gentleman in April 1718. Previouſly to this period, freſh inroads had been made by the tide; and the breach rendered much worſe. After various expedients captain Perry ſucceeded in effecting his purpoſe, but not before the works had been three times nearly waſhed away by the rapidity of the tides. The original contract for this important work was 25,000*l.*; but before its completion, it appeared that 40,472*l.* 18*s.* 8½*d.* had been expended. Of this ſum 15,000*l.* more were afterwards voted by Parliament. Yet this left a minus to the able engineer of almoſt five hundred pounds. Thus was he ungenerouſly left to defray part of the expence, after five years of exertion, anxiety, and care.

A pool ſtill is left, as a memorial of the event, within the embankment, and near it a ſmall houſe, ſupported by the ſubſcription of gentlemen, who form fiſhing parties here during the ſummer months.

While the men were digging in the works, an extenſive ſtratum of various kinds of rotten trees, with a very little intermixture of earth, was diſcovered beneath the ſurface. Among theſe were oak, hornbeam, hazel, willow, and yew; which latter were in an undecayed ſtate. In this foſſil ſtratum, called *moorlogg*, ſeveral ſtags' horns were alſo found lying on the ſurface.

It is a fact worthy of obſervation, that when this breach happened a vaſt inundation alſo took place on the weſtern coaſt; by which all the moors of Somerſetſhire, in the vicinity of Bridgewater, were completely overflowed; much valuable land irrecoverably loſt, and a new channel formed in the bed of Huntſpil river. See Perry's Account of the ſtopping of Dagenham Breach, 8vo. 1721.

DAGERORT, or DAGEROTH, a ſmall town on the extremity of the weſtern promontory of the iſland of Dago in the Baltic, remarkable for a light-houſe which ſtands

about three miles from the ſea, on a mountain computed to be 22 fathoms in perpendicular height.

DAGESTAN, Daghestan, or *Dagiſtan*, a province of Aſia, ſituated on the weſt coaſt of the Caſpian ſea, between the rivers Terek and Kur, or Circaſſia and the province of Schirvan, inhabited by Tartars, and included in the government of Caucaſus. This province includes four ſmall ſtates; the firſt of theſe is the territory of the Schamchal, or Schabaal, ſtretching about 14 German miles along the ſhore of the Caſpian ſea, from the river Kura-Koiſu, a branch of the Koiſu, called the dry Koiſu, becauſe it is deſtitute of water except when the ſnow diſſolves in the mountains, to the rivulet Uruſai-Bulak or Ruſſian Spring, and is in breadth from ſeven to eight German miles. The plain is moſtly in tillage, and being well watered by rivers and brooks that deſcend from the neighbouring mountains, produces corn. In this plain there are only ſheds for cattle; the dwellings of the inhabitants being ſituated in the mountains, which are covered with woods, ſteep and interſected by many narrow glens. The capital is Tarki, ſituated on the declivity of the mountain towards the plain, and ſaid to contain about 10,000 inhabitants, among whom are many Armenian and Georgian merchants: another leſs conſiderable town, called Buinacki or Boinak, is ſituated on a rivulet of the ſame name, where it iſſues from the mountains. The ſecond ſtate is the territory of the Uzmey, between the Uruſai-Bulak and the little Darbach, which is for the moſt part mountainous, about 8 German miles in length, along the coaſt, and equally broad. It is watered by three pretty conſiderable rivers, the Chamraſeni, the great Buam, and the great Darbach, which are divided into ſmall canals for the purpoſe of navigation, and alſo by ſeveral brooks. This tract of country produces abundance of wood and corn, and is well inhabited. The Uzmey reſides in Baſchli, a ſmall town ſeated on the brook of the ſame name, at the diſtance of four German miles from the Caſpian ſea. On the rivulet Jntſché lies the town of Ottemiſch, and many villages are ſituated on the mountains. Along the banks of the Buam the inhabitants are Kaidaks; on the Darbach, Karakaidaks; and between the mouths of the great Buam and Darbach, Bereközes. The third ſtate is the territory of Derbent or Derbend, which is of inconſiderable extent, being only four German miles in length on the ſea-coaſt, and extending from $1\frac{1}{2}$ to 2 miles inland, and owes its importance ſolely to the advantageous ſituation of the city of Derbend. The Darbach and Rubas form the northern and ſouthern boundaries; between which rivers lies a broad and partly marſhy level, interſected by many ſmall brooks, and interſperſed with beautiful and well cultivated corn-fields. For an account of Derbend, ſee Derbend. The fourth ſtate is Tabaſſeran or Tabäſſaran, and lies between the Darbach and Rubas, towards their ſources, extending about ſix German miles inland from above the territory of Derbent, as far as the higheſt ridge of the Leſgian mountains, which is very rocky and woody. Reinegg⁹, in his "General Hiſtorico-topographical Deſcription of Caucaſus," &c. vol. i. eſtimates the ſtrength of the different tribes that inhabit Tabaſſeran, who beſides the Tartarian ſpeak another language peculiar to themſelves, at about 10,000 families; and according to him the reigning family have held the ſovereignty over the country for more than 600 years.

DAGGER, in *Military Language*, a ſhort ſword or poignard, about 14 inches long. This weapon is too frequently employed for the purpoſe of aſſaſſination, and in many parts of the world forms a part of the ordinary dreſs of ſome claſſes. The dagger is ſeen under various forms; in Italy, the *ſtiletto*, as it is there called, is ſmall and eaſily concealed; having generally a very ſmall handle, and a flat, or a triangular blade, grooved very deeply. In the ſouth of France, the *couteau* is more like that kind of knife uſed by our pork-butchers; in Spain, it is more on the Italian plan, and commonly worn in the waiſt, having a ſmall ornamented handle. We had a dagger lately in the Leverian Muſeum, that had appertained to a monk, who committed various murders, ſuppoſed with that inſtrument: it was concealed within the blade of a common table knife, in which it was retained, and could be drawn at pleaſure, by means of a ſpring in the handle. The Malays uſe daggers with ſerpentine blades; theſe are called *creeſſes*, and inflict a moſt deſperate wound; the extent of which, however, is rarely of moment, it being the cuſtom of thoſe people to ſtab into the thorax, between the collar-bone and the *æſophagus*, or gullet. The Perſians, as alſo the people of Aſia in general, conſider the dagger as a part of their full-dreſs, and wear ſometimes two or more of them in their waiſts. The handles of theſe are for the moſt part ornamented with inlaid gold, or with precious ſtones; and the ſheaths are covered with velvet, tipped with gold ornaments. The gripe is formed in a curious manner, conſiſting of two croſs bars, at about an inch aſunder, lying at right angles between two ſtilts, that communicate with the blade; which is of a triangular form, and nearly flat. Daggers are prohibited by ſtatute in this country, and happily are only to be ſeen upon the ſtage, or in muſeums, &c. The wiſdom of the legiſlature was in this eminently conſpicuous, ſince it obviated a train of ſerious miſchiefs naturally reſulting from the immediate readineſs of laying the hand on an offenſive weapon. Hence, although the law makes allowance for the fatal iſſue of ſudden quarrels, where a weapon is *in the hand* of him who deprives another of life, it wiſely exempts the dagger, as being, in itſelf, an indication of malice prepenſe, or of a criminal intention. In many parts of the continent, the lower claſſes decide all their controverſies with knives or daggers; in the uſe of which many exhibit conſummate ſkill: it is, indeed, conſidered there as much a ſcience as our exerciſe with the broad-ſword: trials of proweſs with blunt daggers, being a very common recreation.

DAGGIAL, the name given by the Mahometans to their falſe meſſiah or antichriſt, denoting a perſon with one eye and one eye-brow, who, as they pretend, will make his appearance at the end of the world, mounted on an aſs, in imitation of the true Meſſiah; but they further conceive, that Jeſus Chriſt, who is not yet dead, will then fight with him and put him to death.

DAGNO, in *Geography*, a town of European Turkey, in Albania, on the Drin; 15 miles S.E. of Seutari.

DAGO, Dagen, or *Dagho*, one of the ſmall iſlands of the Baltic ſea, in the bay of Riga, belonging to Ruſſia, lies nearly in the 59th degree of north latitude, and the 24th of eaſtern longitude, exactly oppoſite to another Ruſſian iſland called Oeſel, from which it is ſeparated by a ſmall ſtrait. It is diſtant from the main land upwards of 18, and in ſome places above 30 miles.

The iſland of Dago is of an oblong ſhape, having a promontory, which extends weſtward far into the ſea; a ſmaller one to the north-eaſt, another to the ſouth, and a fourth almoſt due eaſt. The others are leſs conſiderable. Each of the four principal ſides, which are not all quite equal, reaches in a ſtraight line from about 25 to 35, and along the ſhore, on account of its ſinuoſities, to at leaſt 48 miles. In regard to the main body of the iſland, the inhabitants reckon it in length from 30 to 36 miles, and 24 in breadth: but taking the promontories into the account, the right line from

from eaſt to weſt gives a breadth of 48 miles, and from ſouth to north a length of 36 miles. The weſtern promontory is about 18 miles long, and as many broad.

The paſſage from Livonia, the main land, to Dago is uſually either acroſs the iſland of Vorms, or paſſing by the little iſle of Hertholm ſouthward or northward. Many direct their courſe by the village of Vachterby, where a foreſt of alders, ſeen at a great diſtance, ſerves for a landmark. In ſummer time the paſſage is very ſafe acroſs the ſound, even in a ſmall boat: but numerous ſhallows, ſand-banks, and ſmall iſlands render the navigation about Dago ſomewhat perilous in ſtormy weather. Ships are often ſtranded here. At low water the ſand-banks reſemble iſlands: but after long weſterly winds they are overflowed.

No peſtilential diſeaſe was ever known to make any ravages at Dago. The population is ſo great that the eſtates are almoſt overburthened with vaſſals. In ſummer many of them go to the main land, and gain a livelihood by embanking, bricklaying, plaſtering, and frequently whole families are ſold. The landlords would derive no profit from their eſtates, if they were obliged to maintain their vaſſals, and as theſe cannot all live by agriculture, many turn their hands to various arts and handicrafts, in which they ſucceed uncommonly well. The majority of the country people are Eſthonians, though there are whole villages of Swediſh boors, Dago having been conquered, along with Livonia, by the Ruſſians from the Swedes, under Peter the Great.

The iſland of Dago is deficient neither in foreſts nor in ſtone. On the weſtern part is much ſand, but the ſouthern and eaſtern parts conſiſt of a blueiſh clay, and have therefore a fertile ſoil. A conſiderable quantity of good corn is produced, only the ſeed requires to be ſown ſomewhat early. Barley thrives well in rainy ſeaſons. The Swediſh counts De La Gardie were the principal proprietors in the iſlands, and four capital eſtates belong ſtill to one of their deſcendants, the counteſs Steinbock. Tooke's View of Ruſſia.

DAGOBERT I. in *Biography*, king of France, the only prince of that name that appears to have any claim to a place in this work, was ſon of Clotaire II., and born A. D. 602. At a very early age he was appointed, under the direction and aſſiſtance of the biſhop of Metz, and Pepin mayor of the palace, to the government of Auſtraſia. Upon the death of his father, in 628, he ſucceeded to the other parts of the kingdom, allowing, however, his younger brother a ſmall portion as his inheritance. Dagobert engaged in a war with the Sclavonians on the banks of the Danube, in which, at firſt, he was defeated, owing to the diſaffection of his own troops, but, at length, he became victorious, and repreſſed the incurſions of the Sclavonians. The Bulgarians put themſelves under his protection, and, through ſome apprehenſion of his own ſafety, he cruelly and infamouſly ordered 9000 of the people who looked to him for protection to be maſſacred. He extended his power, and the greatneſs of his fame gave him conſiderable influence among ſurrounding nations. His private life was, in the early part of his reign, truly exemplary; but he afterwards became extremely licentious, and, as he advanced in life, he hoped to atone for his miſdeeds by his zeal for the externals of religion, and by founding churches. Among theſe was St. Dennis, celebrated as the burial-place of the French monarchs. In this Dagobert was interred in the year 638. He has been praiſed by hiſtorians on account of his liberality to the church; but he better deſerves applauſe for collecting, reviſing, and making public the laws of his country. In religion, he partook of the bigotry of the times, and iſſued an order for all the Jews in his dominions to ſubmit to Chriſtian baptiſm. Moreri.

DAGOLASSOS, in *Ancient Geography*, a town of the Leſſer Armenia.

DAGON, in *Mythology*, one of the moſt celebrated divinities of the Philiſtines, commonly repreſented as a monſter, half man, and half fiſh; whence ſome have derived his name, the Hebrew word *dag* denoting a *fiſh*. According to Sanchoniathon the origin of this deity is very ancient, and he was the ſon of Cœlus, ſo called from the word *dagan*, which, in the Phœnician language, ſignifies *wheat*. As he was the inventor of the plough, and taught men the uſe of corn for bread, he was, after his death, ſurnamed Jupiter Agrotes, or the labourer; and being the inventor of agriculture, he was deified after his death. We have various conjectures concerning this divinity. According to ſome, he was Jupiter; according to others, Saturn. Others, again, repreſent him as Venus, or a female deity, alleging, that Venus was worſhipped under the form of a fiſh; and Diodorus Siculus relates, that, at Aſhulen, a famous city of the Philiſtines, Derceto, or Atergatis, (the ſame as Venus,) was worſhipped under the figure of a woman, whoſe extremities terminated in the tail of a fiſh. Some repreſented it as having the upper part of a human body, and as a fiſh from the waiſt downwards, while others gave it the form of a fiſh above, and a human figure from the thighs down; and others, again, made it altogether a fiſh. According to an ancient fable, Oannes, a kind of monſter, half man and half fiſh, roſe out of the Red ſea, and came to Babylon, and, having taught ſeveral arts, returned again into the ſea. Several of theſe animals are ſaid to have ariſen from this ſea in ſubſequent ages; one of which was called "Octagon," and hence, ſays Selden, was derived the appellation Dagon. Some have ſuppoſed that Dagon and Neptune were the ſame deity. Bochart conjectures, that Dagon was Japhet, the third ſon of Noah, and that he was made the god of the ſea, becauſe the lot aſſigned to him and his deſcendants included the iſlands, peninſulas, and countries beyond the ſea, or, according to Lactantius, the continent of Europe. Jurieu ſuggeſts, that Noah himſelf, who eſcaped from the deluge, was diſguiſed under the name of Dagon or Neptune. From the Scripture we learn, that when the Philiſtines had taken the ark of God from the Iſraelites, and brought it to the city of Aſhdod, or Azotus, or Azoth, as it was differently called, they placed it in the temple of Dagon, cloſe to the image of that deity; but when they afterwards entered the temple, they found the idol fallen on its face, with its head and hands broken off. The Philiſtines held this idol in great veneration; and erected in honour of it magnificent temples. His temple at Gaza muſt have been very large, ſince Sampſon, having pulled down the pillars that ſupported it, buried more than 3000 men in its ruins. This deity continued to have a temple at Aſhdod, during all the ages of idolatry, till the time of the Maccabees; for we read, that when the army, vanquiſhed by Jonathan, one of the Maccabees, fled to Azotus, and attempted to ſhelter themſelves in Beth-Dagon, or the temple of Dagon, Jonathan ſet fire to Azotus, and burned the temple, and all who fled into it. The head of Saul, as we learn from the book of Samuel, (1 Sam. ch. v.) was placed in one of the temples of this god, and his arms in that of Aſtaroth, whence we may infer that Dagon and Aſtaroth were diſtinct divinities. Banier's Mythology, vol. ii. p. 37. Milton's Par. Loſt, B. i.

DAGONVILLE, in *Geography*, a town of France, in the department of the Meuſe, and diſtrict of Commercy: 3 leagues E. of Bar-le-Duc.

DAGOTI, in *Biography*, ſee GAUTIER.

DAGOUA, in *Geography*, a town of Egypt on the

Nile, ſaid to be a harbour for thieves and pirates; 12 miles N. of Cairo.

DAGOUNG, or SHOEDAGON, *temple of*, ſituated about 2½ miles N. of Rangoon, the chief port of the Birman empire, is a grand building, more ornamented than that of Shoemadoe at Pegue, though not ſo high by 25 or 30 feet. The terrace on which it ſtands is a rocky eminence, conſiderably higher than the circumjacent country. It is aſcended by above 100 ſtone ſteps, now decayed. The ſituation renders it a conſpicuous object at the diſtance of many miles. The top and the whole of the ſpire are richly gilded, which, when the ſun ſhines, exhibit a ſingularly ſplendid appearance. Shoedagon, the name of this temple, which ſignifies golden Dagon, naturally reminds us of the houſe of Dagon, mentioned in Scripture, and the image of idolatry which bowed down before the holy ark. See DAGON.

DAGSBOROUGH, a poſt-town of America, in the county of Suſſex and ſtate of Delaware, ſituated on the N. W. bank of Peper's creek, a branch of Indian river, and containing 40 houſes: 19 miles from Broad-hill or Clowe's, and 127 S. from Philadelphia.

DAGUSSA, in *Ancient Geography*, a town of Aſia, placed by Ptolemy in the country called Melitana.

DAGYSA, in *Zoology*, a genus of the Molluſca tribe, of which only a ſingle ſpecies has hitherto been diſcovered, and which was taken by ſir Joſeph Banks and Dr. Solander in the Spaniſh ſea, as related by Hawkeſworth. Theſe curious animals are three inches long and one in breadth, and adhere to each other by the ſides. They have been deſcribed by ſome writers under the name of *Carcinum opalinum;* and by others are conſidered as appertaining to the Salpa genus. In the Gmelinian ſyſtem the Dagyſa genus is defined as having the body looſe, nayant, angular, tabular, and open at each extremity; and the ſpecies which is named *notata*, as having the body marked at one end with a brown ſpot.

DAHÆ, in *Ancient Geography*, a people who inhabited the territory lying to the eaſt of the Euxine ſea and of the Palus Mæotides, according to Strabo, who claſſes them among the Scythian Nomudes. They are mentioned by Virgil, and deſcribed as the "Indomitique Daæ." Servius (in loc.) ſays that they extended to the northern part of Perſia.

DAHALAC, or DAHHLAK, in *Geography*, the largeſt iſland in the Red ſea, near the coaſt of Abyſſinia. Its whole length from N. W. to S. E. is 37 miles, and its greateſt breadth 18. It is low and even, the ſoil of it is fixed gravel and white ſand, mixed with ſhells and other marine productions. In ſummer it is deſtitute of all ſorts of herbage, except a ſmall quantity of bent graſs, ſufficient to feed the few antelopes and goats that are on the iſland: of the laſt animal there is a beautiful ſpecies, ſmall, ſhort-haired, with thin black ſharp horns, having rings upon them, and very ſwift-footed. This iſland is in many places covered with large plantations of acacia trees: although it is in the neighbourhood of Abyſſinia, it does not partake of its ſeaſons; no rains falls here from the end of March till the beginning of October; but in the intermediate months, eſpecially December, January, and February, there are violent ſhowers that laſt 12 hours, deluge the iſland, and fill the ciſterns ſo as to ſerve for the enſuing ſummer; as the iſland has no hills or mountains, and conſequently no ſprings. Of theſe ciſterns for preſerving water, there are 370, all hewn out of the ſolid rock. Tradition ſays that they are the works of the Perſians; but Mr. Bruce ſuggeſts that they were more probably conſtructed by the firſt Ptolemies. After the fall of rains, the graſs immediately ſprings up; which ſerves to feed the goats that ſupply the inhabitants with milk, the chief article of their ſubſiſtence in winter, for they neither plough nor ſow. Their whole employment conſiſts in working the veſſels which trade to the different parts of the coaſt. The ſuſtenance of the poorer ſort is altogether ſhell and other fiſh. The women are very adventurous expert fiſhers. Theſe miſerable people, who live in the villages not frequented by barks from Arabia, ſubſiſt ſometimes for a whole year without taſting bread: and yet ſuch is their attachment to their native ſoil, that they prefer this barren and parched ſpot, deſtitute of almoſt all neceſſaries, eſpecially ſuch as are moſt eſſential, bread and water, to thoſe pleaſant and plentiful countries that lie on both ſides of them. People of the better ſort have a brown complexion, but thoſe of the common ſort, who are employed in fiſhing, are of a reddiſh hue, ſomewhat darker than the colour of new mahogany. Among them are alſo blacks, who come from Arkeeko and the Main; but theſe, upon marrying, become leſs black in the courſe of a generation. The inhabitants of Dahalac are a ſimple, timid, inoffenſive people, who carry no kind of hoſtile weapon. The iſland is ſalubrious, and yet none of the inhabitants ſeem to attain an age of more than 60 years.

The ſouthern cape of this iſland, called "Ras Shouke," which in Arabic ſignifies the Cape of Thorns, becauſe it has upon it a number of acacia-trees, is in N. lat. 15° 27′ 30″; and the northern cape, or "Ras Antalou," is in N. lat. 15° 54′; 30″; the longitude of the iſland is 39° 20′ E. The harbour of Dobelew is of a circular form, and ſufficiently defended from all winds, but its entrance is too narrow, and within it is full of rocks, conſiſting of ramifications of white coral intermixed with large black ſtones. Three miles S. W. of the harbour is the village, called Dobelew, conſiſting of about 80 houſes, built of calcinable ſtone, drawn from the ſea, and covered with bent graſs. The ſouth-weſt extremity of the village is in N. lat. 15° 42′ 22″. Irwee, a ſmaller village, lies at the diſtance of about four miles from Dobelew, and is ſituated in the centre of the iſland. In Dahalac there are 12 villages or towns, little different in ſize from Dobelew; each has a plantation of doom-trees round it, which furniſh the only manufacture in the iſland; the leaves of this tree, when dried, are of a gloſſy white, which may be eaſily miſtaken for ſattin; and of theſe are made baſkets, that are very neat and beautiful, and ſo well wrought, that they will contain water for 24 hours without leaking.

Dahalac depends upon Maſuah, and is conferred by a firman from the grand ſignior, on the baſha of Jidda, and from him on Metical Aga, then on the Naybe, and his ſervants. The revenue of the governor conſiſts of a goat brought to him monthly by each of the 12 villages. Every veſſel, that puts in there from Maſuah, pays him alſo a pound of coffee; and every one from Arabia, a dollar or pataka. No ſort of ſmall money is current at Dalahac, except Venetian glaſs-beads, old and new, of all ſizes and colours, broken and whole.

Notwithſtanding the preſent miſerable ſtate of this iſland, the pearl-fiſhery was very flouriſhing here under the Ptolemies; and long after, in the time of the caliphs, it produced a great revenue, and till the ſovereigns of Cairo began to withdraw themſelves from the dependency on the Porte, Dahalac was the principal iſland that furniſhed the pearl fiſhers, or divers. It was, indeed, the chief port for the fiſhery on the ſouthern part of the Red ſea, as Suakem was on the north; and the baſha of Maſuah paſſed part of every ſummer here, to avoid the heat at his place of reſidence on the continent. The fiſhery extended from Dahalac and its

iſlands nearly to lat. 20°. The inhabited iſlands furniſhed each a bark, and ſo many divers, and they were paid in wheat, flour, &c.; ſo that a few months employment furniſhed them with every thing neceſſary for the reſt of the year. The fiſhery was rented, in later times, to the baſha of Suakem. The pearls found here were of the largeſt ſize, and inferior to none in water or roundneſs. Tradition ſays, that this was excluſively the property of the Pharaohs, or the old kings of Egypt before Mahomet. In the ſame extent between Dahalac and Suakem, there was another very valuable fiſhery, that of tortoiſes, from which the fineſt ſhells of that kind were produced; and a great trade was carried on with the Eaſt Indies, (China eſpecially) at little expence, and with great profit. The animal itſelf was very plentiful between lat. 18° and 20°. In proceſs of time Dahalac became dependent on the baſha of Jidda, and he appointed an aga, or ſubaltern governor, who paid him a moderate ſum, and appropriated to himſelf the greater part of the proviſions and ſalary allowed for the pearl fiſhery. When the princes of Arabia became again free from the Turkiſh power, Dahalac, Maſuah, and Suakem, returned to their ancient maſters, to whom they are now ſubject, governed, indeed, by ſcheiks of their own country, and preſerving only the name of Turkiſh government, each being under the command of a robber and aſſaſſin.

The immenſe treaſures at the bottom of the Red ſea have been abandoned for near 200 years, though they were probably never richer than they are at preſent. A ſettlement upon the river Frat, in N. lat. 21° 28′, which has never yet belonged to any but wandering Arabs, might open to the Eaſt India company a market both for fine and coarſe goods from the ſouthern frontiers of Morocco to Congo and Angola, and ſet the commerce of pearls and tortoiſe-ſhell again on foot. The whole portion of the gulf from Suez, ſays Mr. Bruce, is in their charter; and 20 ſhips might be employed on the Red ſea, without any violation of territorial claims. At Dahalac they have neither horſes, dogs, ſheep, cows, nor any ſort of quadruped, except goats, aſſes, a few half-ſtarved camels, and antelopes, which laſt are very numerous. The inhabitants have no knowledge of fire-arms; and there are no dogs nor beaſts of prey in the iſland to kill them; ſome few, indeed, are caught in traps.

The language at Dahalac is that of the "Shepherds;" Arabic too is ſpoken by moſt of the inhabitants. From this iſland are ſeen the mountains of "Habeſh," running in an even ridge like a wall, parallel to the coaſt, and down to Suakem. Bruce's Travels, vol. i. B. i.

DAHHMAK, a town of Arabia, in the country of Yemen; 16 miles S.S.E. of Abu-Ariſch.

DAHL, Michael, in *Biography*, a painter, native of Stockholm, who at an early age came into England, being introduced into this country by an Engliſh merchant. Dahl afterwards travelled to Paris, and reſided there ſome time. He then viſited Italy, where he painted, amongſt others, the portrait of queen Chriſtina of Sweden. In 1688 we find Dahl returned to England, where he acquired ſome reputation as a portrait painter. He died in London in 1743 at the advanced age of 87 years. The following portraits are a few of thoſe engraved after this artiſt: Joſeph Addiſon, 1719, by Simon; queen Anne, by W. Faithorne; prince George of Denmark, by J. Simon; the duke of Marlborough, by ditto; the duke of Ormond, by ditto. Walpole.

Dahl, or Dal, in *Geography*. See Dal Elbe.

DAHLBERG, Eric, in *Biography*, a celebrated Swediſh general, whoſe talents and virtues led him to the higheſt diſtinctions in his country, was born in October, 1625. His education was very limited, but by dint of application, and with ſcarcely any aſſiſtance, he made a rapid progreſs in mathematics, a ſcience always of the laſt importance to thoſe who are deſtined for high military command. The elements of geometry he took great pains to apply to the art of fortification, and to his ſucceſs in this he was indebted for the rank to which he afterwards attained. In 1648 he was appointed engineer under Guſtavus Adolphus, and in 1656 he joined the army in Poland, and was appointed lieutenant-general-quarter-maſter of the main diviſion. During the moſt remarkable events of the war in Poland, he was the attendant, and probably chief adviſer of his ſovereign. In the following year, when the king found it neceſſary to tranſport his army to Denmark, Dahlberg was ſent to ſurvey the Great Belt, then frozen over, and in conſequence of his opinion his majeſty reſolved to march his army acroſs the ice, by which he ſpeedily made himſelf maſter of the whole country, to the very walls of Copenhagen. From this time he was employed in the moſt important offices, both as a military commander, and alſo in political miſſions. So much did he improve the ſtate, and augment the ſtrength of his country, that he has with great juſtice been ſtyled the Swediſh Vauban. In 1696 he was appointed governor of Livonia, which he defended when invaded by the Saxons in 1700. He died at Stockholm in 1703, in the ſeventy-eighth year of his age. He left behind him a work of great merit entitled "Suecia Antiqua Hodierna," in three vols. folio. This work conſiſts of plates only, and the drawings from which they were executed were almoſt all taken on the ſpot by Dahlberg himſelf. Gen. Biog.

DAHLEN, in *Geography*, a ſmall town of Saxony, in the circle of Meiſſen or Miſnia, with 916 inhabitants, belonging to the counts of Bunau, and remarkable for extenſive plantations of mulberry trees and large crops of the beſt madder.

DAHLIA, in *Botany*, (named by the late prof. Cavanilles in honour of Andrew Dahl, a Swediſh botaniſt, author of a little volume of botanical obſervations.) Cavan Ic. Plant. v. 1. 56. t. 80. (Georgina. Willd. Sp. Pl. v. 3. 2124.) Claſs and order, *ſyngeneſia polygamia-ſuperflua*. Nat. Ord. *Corymbiferæ*, Juſſ.

Gen. Ch. *Common Cal.* double; the outer of ſeveral leaves, ſix or ſeven, ovato-ſpatulate, reflexed; inner of one leaf cup-ſhaped, in ſeveral ovate ſegments. *Cor.* compound, radiant; florets of the centre perfect, with a tubular, ſtalked, five-cleft petal; thoſe of the radius fertile, with an ovate three-toothed petal, equal in number to the ſegments of the calyx. *Stam.* (in the perfect florets,) filaments five, broadeſt at the baſe, inſerted into the bottom of the petal; anthers united into a tube. *Piſt.* Germen ſomewhat ſpatulate, obſcurely triangular, notched at the top; ſtyle thread-ſhaped; ſtigmas ſomewhat ſpreading, pubeſcent. *Seeds* ſolitary, ſhaped like the germen. *Recept.* flat, chaffy; the ſcales large, the middle ones keeled, the reſt flat. *Down* none.

Eſſ. Ch. Calyx double; the outer of many leaves. Corolla radiant, its rays equal in number to the ſegments of the calyx; ovate, three-toothed. Receptacle chaffy. Stigmas downy. Seed-down none.

This genus comes very near Polymnia, and Dr. Sims has obſerved in one ſpecies, D. *coccinea*, Curt. Mag. t. 762, that the florets in the centre of the diſk are barren, thoſe in its circumference fertile, the radius being neuter or abortive, ſo that the genus, if all its ſpecies agreed in this reſpect, ſhould be referred, like Polymnia, to the order *Polygamia-neceſſaria*.

The

The ſpecies of Dahlia are ſeveral, all natives of mountainous parts of the Spaniſh ſettlements in South America. Their flowers are large and handſome, like thoſe of a ſunflower, but the rays moſtly red or purple like the China-aſter, and likewiſe variable in this reſpect. The herbage is coarſe and rank, with compound leaves. The moſt complete hiſtory of the genus is juſt given in the ſecond part of the Tranſactions of the Horticultural Society by Mr. Saliſbury, who recommends the cultivation of ſome ſpecies in poor gravelly ſoil, in the open ground, by which means they grow leſs luxuriantly, and flower earlier and more copiouſly.

DAHME, in *Geography*, a ſmall town of Saxony, in the principality of Querfurt, with 1964 inhabitants, and remarkable for its manufactures of linen and woollen cloth and worſted ſtockings. It has a royal palace, an infirmary, and an orphan-houſe. Its diſtrict contains 14 villages, and counts a population of 4162 individuals.

DAHMEC, a town of Aſia, in the country of Candahar; 28 miles S.W. of Candahar.

DAHN, a ſmall town of France, in the department of the Lower Rhine, chief place of a canton, in the diſtrict of Weiſſembourg. The place contains 608, and the canton 4892 inhabitants, diſperſed in fifteen communes on a territorial extent of 225 kiliometres. Dahn is 9 miles N.W. of Weiſſembourg.

DAHOMAY, Dauma, or, as it is ſometimes called, Fouin, an inland kingdom of Africa, ſituated N. of the Slave Coaſt, about 60 or 70 miles from the Atlantic, and extending 150 or 200 miles into the unknown interior of the country. It is ſaid to be bounded by Gaoga and Tombucto on the weſt, Bita on the north, Biafara on the eaſt, and the mountains of Guinea on the ſouth. It lies behind the maritime coaſt of Whidah, and is ſaid by Norris, in his "Memoirs of the reign of Boſſa Ahadee, king of Dahomy, &c." publiſhed in 1717, to have received its name from Tacoodonou, a chief of the Foy nation, early in the 17th century, who reduced Da, king of Ahomay, ripped open the belly of Da, and placed the body under the foundation of a palace, which he built in his newly acquired territory, as a memorial of his conqueſt. This he called Dahomy, from *Da*, the name of this unfortunate victim, and *homy*, belly; that is, a houſe built in Da's belly. Of this country very little was known, prior to the reign of Guadja Trudo, who ſucceeded Wacbaigah in 1708. Trudo was diſtinguiſhed by courage, generoſity, and magnanimity; and his memory continued to be held in ſuch veneration by the Dahomans, that they even ſwore by his name as the moſt ſolemn of all aſſeverations; but, notwithſtanding his ſplendid qualities, he appears to have entailed, by his ambition, laſting miſeries on his country. He was ſucceeded in 1732 by his ſon Boſſa Ahadee, who was raiſed to the throne by the two prime miniſters, to whom belongs the right of chuſing the future monarch, in preference to his brother Zingah. Zingah, preparing to aſſert his right, was ſeized, and it being unlawful to ſhed royal blood, he was ſewed up in a hammock, and thrown into the ſea. One of the firſt edicts of the new king was, that every man of the name of Boſſa throughout his dominions ſhould be put to death, as he thought it an inſult to majeſty, that any of his ſubjects ſhould bear his name. Another inſtance will be ſufficient to mark the character of this negro prince. When his father reduced the Whidahs, the greater part of the conquered nation deſerted their country, and ſettled in a neighbouring ſwamp, where they frequently haraſſed the Dahomans. Theſe refugees continued under a king; and on a diſpute between two brothers for the ſupreme power, Boſſa Ahadee, to improve this diviſion, patroniſed the younger, who engaged to become his tributary; and as a teſt of his fidelity, Boſſa required him, on the murder of his brother, to devour his heart; it is added, that this unnatural condition was fulfilled! During the long reign of this cruel and ferocious tyrant, Boſſa Ahadee, the country was haraſſed and waſted by wars, foreign and domeſtic, in which multitudes were ſlain; but nothing fills the mind with ſo much horror as the ſacrifices of human victims for the purpoſe of watering (according to the country expreſſion) the graves of the deceaſed royal family. Without ſuppoſing that the Dahoman monarchs can receive ſome pleaſure from the contemplation of the monuments of their vengeance and wanton cruelty, it is difficult to account for their paſſion for decorating the walls of their houſes and their apartments with the ſkulls and bones of the unhappy wretches who have periſhed by their hands. In the reign of Adahoonzou, the ſucceſſor of Boſſa Ahadee, after the ſlaughter of the priſoners whom he had taken in war, their ſkulls were ordered to be applied to the decoration of the royal walls. On one occaſion, a calculation having been made that 127 ſkulls were wanted for the completion of this extraordinary embelliſhment, the priſons were thrown open, and the requiſite number of devoted victims dragged forth from among the wretched captives, to be ſlaughtered in cold blood, for this helliſh purpoſe. Previouſly to their execution, they were informed that the heads brought home by the Agaow had not been found ſufficient to garniſh the palace, and that theirs were required to ſupply the deficiency. This act of barbarity was applauded by all preſent.

The capital of this kingdom, Abomey, lies in about N. lat. 9° 50′., and between 3° and 4° E. long. The country is fertile and luxuriant; the ſoil is a deep rich clay of a reddiſh colour, with a little ſand on the ſurface, except about Calmina, where it is more light and gravelly; but through the whole country, as far as it has been examined by Europeans, there is not found a ſtone as big as an egg. The country yields a plentiful ſupply of farinaceous vegetables, ſuch as maize, millet, kidney beans, called callavances, and a ſpecies of beans called ground beans. The Dahomans likewiſe cultivate yams, potatoes, the caſſada or manioc, the plantain, and the banana. Pine-apples, melons, oranges, limes, guavas, and other tropical fruits, are alſo abundant. Nor is it deſtitute of productions adapted for commerce and manufacture; ſuch as indigo, cotton, the ſugar-cane, tobacco, palm-oil, together with a variety of ſpices, particularly a ſpecies of pepper, ſimilar in flavour to the black pepper of the Eaſt Indies, and ſcarcely diſtinguiſhable from it. The Dahomans, like the other inhabitants of tropical climates, plant twice a-year, *viz.* at the vernal and autumnal equinoxes, after which the periodical rains fall. The language of the country, called by the Portugueſe "lingua geral," or general tongue, is ſpoken not only in Dahomy proper, but in Whydah, and the other dependent ſtates; and likewiſe in Mahee and ſeveral neighbouring places. With reſpect to the Dahoman religion, it conſiſts of a jumble of ſuperſtitious ceremonies, of which it is not poſſible to convey to the reader any intelligible and ſatisfactory account. The Portugueſe word "feitiço," or as the Engliſh pronounce it "fetiſh," ſignifying witchcraft, has been adopted by moſt of the maritime nations of Africa, as well as by the Europeans who trade thither. The term is now comprehenſive in its ſignification, and includes either the ſeveral objects of worſhip, ideal or corporeal, the act of worſhip itſelf, or the various amulets, charms, and ſuperſtitious mummery of the prieſts, or fetiſhmen, who abound in this country. They obſerve no ſabbath, unleſs their market days, which are conſidered as days of recreation, may be ſo called. Moſt of the ſavage nations have ſome confuſed ideas of a ſupreme intellectual Being, the maker of the univerſe; but theſe ideas not being eaſily

underſtood among a people unaccuſtomed to metaphyſical reaſoning, a variety of material and corporeal beings have been ſelected as objects of devotion, ſuch as the ſun, moon, living animals, trees, and other ſubſtances. The tiger is the fetiſh of Dahomy; the ſnake, that of Whydah. Among the amulets or charms, the principal is a ſcrap of parchment, containing a ſentence of the Koran, which the natives purchaſe from the moors who viſit this country. This they hang up in their apartments, which are likewiſe decorated with rude miſhapen images, tinged with blood, beſmeared with palm-oil, ſtuck with feathers, bedaubed with eggs, and other abſurd applications, of which a particular account would be both tedious and unprofitable.

As to the nature of the Dahoman government, it is the moſt perfect deſpotiſm that exiſts, perhaps, on the face of the earth; nevertheleſs, at particular times, the moſt licentious anarchy prevails; for, on the death of the king, till the appointment of his ſucceſſor, the government is diſſolved; and a horrid ſcene commences in the palace immediately on the king's deceaſe. His wives begin with demoliſhing the furniture of the houſe, the gold and ſilver ornaments and utenſils, the coral, and, in ſhort, every thing valuable that belonged either to themſelves or to the late king, and then murder one another. The policy of the country admits of no intermediate degree of ſubordination between king and ſlave; at leaſt in the royal preſence, when the prime miniſter is obliged to proſtrate himſelf with as much abject ſubmiſſion as the meaneſt ſubject: all acknowledging the right of the ſovereign to diſpoſe of their perſons and property at pleaſure. Beyond the precincts of the palace, indeed, the miniſters enjoy very eminent privileges, and are diſtinguiſhed by a variety of inſignia, and by the ſervile homage of their inferiors. One of the miniſters, peculiarly dreſſed and equipped, is always found in waiting at the king's gate; but is never allowed to enter till the monarch ſignifies his permiſſion by one of the women. On his entrance, he crawls into the royal preſence on his hands and knees, rubbing his head in the duſt, and uttering the moſt humiliating expreſſions. No perſon is permitted to ſit, even on the floor, in the king's preſence, except the women; and they muſt kiſs the earth, when they receive or deliver the king's meſſage. The king, and all his ſubjects, receive ſtrangers with the moſt remarkable courteſy; and every one ſalutes the ſovereign according to the faſhion of his own country, without being under the previous neceſſity of learning the court etiquette. White viſitors are always honoured with a glaſs of ſome cordial liquor, filled by the king himſelf; and the refuſal of it gives offence. When a ſubject receives a favour of this kind, he lies on his back, while the king holds the bottle to his mouth, and he is obliged to drink till the royal hand be withdrawn. The doctrine of paſſive obedience and non-reſiſtance is univerſal among the Dahomans, and the moſt oppreſſive mandates of the monarch are ſubmitted to without a murmur.

The king of Dahomy maintains a conſiderable ſtanding army, commanded by an agaow, or general, with ſeveral other ſubordinate military officers. The payment of theſe troops chiefly depends on the ſucceſs of the expeditions in which they are engaged, at the king's peremptory and irreſiſtable orders. On extraordinary occaſions, all the males, able to bear arms, are obliged to repair to the general's ſtandard; every "Caboceer" (formed from the Portugueſe, *cabecciro*, a head-man) marching at the head of his own people. The king himſelf ſometimes takes the field at the head of his troops; and, on peculiar emergencies, at the head of his women. For, within the different royal palaces in Dahomy, 3000 women, at leaſt, are immured: of theſe ſeveral hundreds are trained to the uſe of arms, under a female general and ſubordinate officers; and they go through their evolutions with as much expertneſs as the male ſoldiers. They have their large umbrellas, their flags, their drums, trumpets, flutes, and other muſical inſtruments. The flute, though ſimple, open at both extremities, and having a ſmall notch at the mouth end, is capable of producing very agreeable notes; and the king's women underſtand and practiſe the combination of the perfect concords, thirds, and fifths, and their little airs are not inelegant.

The chief part of the public revenue conſiſts of voluntary gifts, paid by the ſubjects at the time of the annual ceremonies, called the "Cuſtoms," when the Caboceers and traders attend, bringing their contributions, according to their reſpective circumſtances. Beſides theſe, a duty is levied on commerce, and ſomething ariſes from captives taken in war, all of whom that are carried to market being ſold on the king's account; but, as he pays a certain ſum to his troops for every priſoner, and as moſt of the captives are put to death, few are reſerved for ſale. The currency of this country conſiſts of the well-known ſhells called cowries, 1000 of which are reckoned equal to half a crown. All diſburſements from the king's houſe are made in bunches of ſtrung cowries, containing 2000 each, deducting $\frac{1}{40}$th part as a perquiſite to the king's women for piercing and ſtringing them. Of theſe diſburſements, a conſiderable part conſiſts of an annual tribute paid to a formidable neighbour, the king of Eyeo, ſituated north-eaſt from Dahomy. The king of Dahomy has ſeveral palaces, each occupying a piece of ground nearly a mile ſquare; that at Calmina, called "Simbamy," or a great houſe, is encompaſſed with a very ſubſtantial clay wall, of a quadrangular form, and about 20 feet high. In the middle of each ſide is a guard-houſe, with two centinels at the gate, and a guard of armed women and eunuchs within. On the thatched roofs of theſe guard-houſes, are ranged, on ſmall wooden ſtatues, many human ſkulls. Within are ſeveral large courts, ſurrounded by clay walls, and having in each of them a ſort of piazza or ſhed, formed of poſts about 7 feet high, at the diſtance of 12 or 14 feet from the wall; the intermediate ſpace is covered with a ſlanting thatched roof, ſupported by bamboo rafters. In the middle of the palace is a large building, of two ſtories, and about 30 or 40 feet high, ſo that the top of it is viſible from without. The receſſes of the palace are ſcarcely ever entered by men; and the female apartments are guarded from intruſion, with more than eaſtern jealouſy. The vulgar among the Dahomans affect to believe that their king does not eat; and, indeed, he does not eat in public, though he makes no ſcruple to drink. However, he entertains the whites with great hoſpitality, and with diſhes prepared by European cooks. The table-cloth, on ſuch occaſions, is a new piece of linen, cut off for the purpoſe; the diſhes are of pewter or earthen ware; and the knives and forks are ſilver-handled. The white men are ſeated on chairs; but the caboceers, and heir-apparent, are placed on the ground near the Europeans, who hand them ſome of the victuals; which they eat, as if by ſtealth, without knife or fork.

The dreſs of the men in Dahomy conſiſts of a pair of ſtriped or white cotton drawers, of the manufacture of the country, over which they wear a large ſquare cloth of the ſame, or of European manufacture. A piece of ſilk or velvet, 16 or 18 yards, forms cloth for a caboceer. The head is uſually covered with a beaver or felt hat; and the king, and alſo ſome of his miniſters often wear a gold or ſilver laced hat, with a feather; the arms and upper part of the body are generally naked; and the feet are always bare, none but the

ſovereign

ſovereign being permitted to wear ſandals. In the hand is uſually carried either a cutlaſs or wooden club; that of an officer of ſtate is ivory. Inferior caboceers carry a ſort of blunt ſabre, with a broad blade and wooden handle; warriors wear what is called a graſs-cloth, made in the country of the ſkin of palm-tree leaves, parted into ſmall threads, knotted and wove, and tinged with various dirty dyes, which is wrapped round the loins. They alſo wear a cartouch-box of their own manufacture, a powder-flaſk of calibaſh, with many groteſque ornaments and fetiſhes, which, together with the uncouth devices painted on their faces and bodies, give them a very fiend-like appearance. Every Dahoman man carries alſo a tobacco pouch, containing tobacco, a flint, ſteel, and tinder; together with one or two tobacco pipes, in a neat wooden caſe. The dreſs of the women conſiſts of a greater number of articles than that of the men. Their ornaments are beads and cowries, and rings of ſilver or baſer metal. Their ears are pierced, ſo as to admit a coral bead of the ſize of the little finger, or a portion of red ſealing-wax, or a piece of poliſhed oyſter-ſhell. Girls, before the age of puberty, wear nothing but a ſtring of beads or ſhells round the loins, and young women uſually expoſe the breaſts to view. The Dahomans are leſs addicted to the practice of *tattowing* the body than their neighbours; contenting themſelves with a perpendicular inciſion, which leaves a mark between the eye-brows.

Circumciſion is univerſally practiſed in Dahomay, but not at ſo early an age as among the Jews; and it is ſo indiſpenſible that the females do not admit the careſſes of the uncircumciſed. A certain operation, peculiar to this country, is likewiſe performed upon the women: "prolongatio artificialis labiorum pudendi, capellæ mamillis ſimillima." The Dahoman women do not admit the embraces of their huſbands during pregnancy, nor at the time of ſuckling, which continues two or three years, nor at the time of the catamenia; during which they retire to a part of the town allotted for their reception. The proſtitutes, licenſed by royal authority, are obliged to confine themſelves to a particular diſtrict, and are ſubject to an annual tax.

The general character of the Dahomans is marked by a mixture of ferocity and politeneſs. They are brave, hoſpitable, generous; and, where the tranſactions of their government allow, affable and communicative.

The annual ceremony, called "Cuſtoms," is uſually celebrated ſoon after Chriſtmas, on which occaſion the king leaves Calmina, where he generally reſides, and repairs to Abomey, his ancient capital, and the burial-place of his family. He then invites, by ſpecial meſſengers, called "half-heads," becauſe half of their heads is ſhaved, the European governors at Grigwee, to witneſs the ſolemnization of this feſtival. Each governor brings his annual preſent, conſiſting of various articles, in value amounting to about 50*l.* ſterling.

For this preſent the king returns more than an equivalent; ſuch as a young female ſlave, and one fine cotton cloth, entertaining his gueſts during their ſtay, with great liberality and kindneſs. On their journey thither they are accommodated at caravanſeras, provided for their convenience, and on their arrival at Abomey, they are received with a ſalute of cannon, and lodged in ſuitable apartments. The celebration of the "Cuſtoms" uſually continues about a month, during which there is ſome public exhibition every fourth, or market day, the intermediate days being employed in preparations. One of the market days is ſet apart for ſinging and dancing; the ſongs are extemporary, in praiſe of the monarch and his exploits, and the performers are rewarded according to the merit of their compoſitions. The bards alſo rehearſe the whole hiſtory of their country, which continues ſeveral days, during which they ſit at the king's gate. Another day is allotted for feaſting in the market-place, where tents are pitched for the accommodation of the king, caboceers, white viſitors, and embaſſadors from foreign ſtates. Various other ſcenes are exhibited during this carnival, which cloſes with a ſingular exhibition, on a ſtage erected and prepared for the purpoſe, of cowries ſtrung in bunches of 2000 each, pieces of brocade and other ſilks, ſtrings of coral, European and country cloths, Brazil tobacco, pipes, bottled liquors, and a variety of other articles. At an appointed time the king, with his caboceers and vaſſals, repair to the ſtage; and each perſon preſent ſelects a cloth according to his rank; and ſometimes a ſtring of coral is preſented to each. The king, then, throws a bunch of cowries over the fence that guards the ſtage among the multitude; the caboceers, and Europeans, following his example, toſs over all the goods, except a few bunches of cowries, which are reſerved for ſome of the favourite ſervants. The rabble, prepared for this ſport, contend for the ſeveral prizes. But, as an effuſion of blood commonly forms a part of a Dahoman exhibition, this ſcene is cloſed with the death of at leaſt one victim, who, together with ſeveral other animals, is thrown, bound, from the ſtage, to be murdered below.

The Dahomans diſplay great ingenuity, conſidering the rude ſimplicity of their tools, in their ſpecimens of art. Although their looms are very aukward machines, yet they manufacture cloths of cotton, held in high eſtimation among themſelves, and often purchaſed by the Europeans for counterpanes, at a high price. They likewiſe weave cloths of the palm-tree leaves, which they ſometimes dye, but more frequently wear in the natural colour, which is ſomewhat higher than that of nankeen. They likewiſe make neat mats of the ſame ſubſtance. The forges uſed by their ſmiths are of a very ſimple conſtruction; and yet they contrive to fabricate not only the neceſſary inſtruments of huſbandry, but carpenters' tools, cutlaſſes, ſpears, and other weapons. They have alſo braziers or ſilver-ſmiths, who make bracelets, handles for cutlaſſes, rings for the fingers, and other trinkets of braſs or ſilver, which they melt in crucibles of their own manufacture. They make likewiſe earthen pots, water jars, and other utenſils, of the ſame materials. The cookery of the Dahomans comprehends but a few diſhes; theſe, however, are excellent; of which black ſoup is the chief. This is made either of fleſh or fiſh, with a variety of mucilaginous vegetables, well ſeaſoned with pepper and ſalt, and enriched with palm-oil. An exquiſite flavour is given to this diſh by an ingredient made of the ſeeds of a tree, called in the country wild tamarind, ſomewhat reſembling thoſe of the cucumber. Their bread is made of maize or millet, ſometimes boiled into a ſtiff pudding, and ſometimes baked, either with or without leaven. They make alſo a very light white and delicate fermented bread of calavanſes, firſt ſtripped of the huſks, and a kind of paſte or flummery of fermented Indian corn, not unlike blanc-mange, though not ſo adheſive. The Dahomans are at all times very cleanly in their perſons, and particularly ſo with reſpect to their food, and the utenſils uſed in the kitchen and at table. A very good ſoup is manufactured in the country of palm-oil and pot-aſh.

From a remarkable ſpeech of Adahooneou to Mr. Abſon, when he was informed of what had paſſed in England on the ſubject of the ſlave-trade, we are led to infer that the Dahomans never go to war for the purpoſe of ſupplying European ſhips with ſlaves, and that they never ſell their wives and children for the ſake of procuring a few kegs of brandy. We cannot,

not, however, forbear lamenting the misery of those people, by whom a transportation into a distant country, accompanied with slavery, is considered as a situation to be envied. See "The History of Dahomy, an inland kingdom of Africa;" compiled from authentic Memoirs, with an Introduction and Notes. By Archibald Dalzel, formerly governor at Whydah, and now at Cape Coast Castle, 4to.

DAHRA, a small island in the Red sea, near the coast of Arabia; one league S.W. of Loheia.

DAHRIJE, a town of Egypt, situated on the Nile; 13 miles S.S.W. of Damietta.

DAIBOTH, in *Mythology*, an idol of the Japanese, in honour of whom they have erected many temples, to which numerous devotees and worshippers resort. The access to the chief temple of this deity lies through a kind of gateway, on either side of which are two monstrous figures with several arms, holding arrows, swords, and other offensive weapons. The idol is seated in the centre of the pagoda, on a table-altar, elevated above the ground. His height is such, that he touches the roof of the temple with his hand; and his bulk is so enormous, that his hands are more extended than the body of an ordinary man. This idol has the breasts and face of a woman, and black locks, which are crisped and woolly, like those of a negro. He is encompassed on all sides with gilded rays, on which are placed many images, representing the inferior idols of the Japanese. Others are placed on pedestals, and crowned with a nimbus or glory. The altar on which he rests is furnished with a profusion of lighted lamps. The temple is supported by wooden pillars, consisting of trees in their natural and unformed state, so as to give the building a romantic appearance. The frame-work is painted red, and near it is a chapel, externally varnished, in which the sacrifices are prepared, and where the people worship, except on the greater festivals.

DAIGREMONT, M. in *Biography*, a French engraver, who flourished towards the end of the 17th century. He was the disciple of Pierre le Pautre, and assisted J. Berrain in the Books of Ornaments, published in Paris. Besides these, we have by his hand some prints of architecture, and a set of Views of Versailles. At length he quitted the graver to engage in commercial pursuits. Heinecken.

DAIKOKU, in *Mythology*, a Japanese deity, whom the people regard as the source of all their riches. This idol is seated on a sack of rice, the oriental symbol of plenty, and holding in his hand a hammer, by every stroke of which he confers every kind of domestic convenience, gay habits, and great riches.

DAILE, in a ship, the trough wherein the water runs over the decks.

DAILLE', John, in *Biography*, a French protestant minister of considerable celebrity, was born in the year 1594. He was designed by his father for business, but his inclination being decidedly for books, he was inducted into the learned languages and philosophy by the most celebrated professors of the age and country in which he lived. In 1612 he undertook the education of the grandsons of M. du Plessis-Mornay. This he esteemed a most fortunate occurrence, as giving him the friendship and assistance of the grandfather, who frequently read with him books of the highest interest, and imparted to him those rich stores of learning and knowledge with which his own mind was imbued. Seven years did M. Daillé reside in the family of this excellent and venerable man, when he set out with his pupils on their travels. In Italy one of the young men died, and it was with difficulty that the tutor, by the aid of the excellent father Paul, was enabled to transmit the body to France, to be interred with his ancestors. From Italy he accompanied his surviving pupil to Switzerland, Germany, Flanders, Holland, and England, and returned to his native country in the year 1621. Shortly after, he engaged in the ministerial functions, under the patronage of M. du Plessis-Mornay, who in a very short time died in the arms of M. Daillé. He now engaged in revising and preparing memoirs of his friend, which had been collected by De Ligues, and which were afterwards published in two volumes. He was in 1625 elected minister of the church at Saumur, where he had scarcely been a year when he was called by the consistory of Paris to take charge of the church at Charenton. Here he spent the remainder of his life, and was regarded as one of the most excellent as well as judicious defenders of the Protestant cause. He died in the year 1670, at Paris, much esteemed by the Catholics, as well as by the Protestants, for his learning, abilities, integrity, moderation, and his polite and obliging manners. By his works he was distinguished among contemporary writers, as well for his candour, as for the strength of his arguments, and the clearness of his style. The principal works published by M. Daillé, and which we shall notice, are, 1. "De l'Usage des Peres," or "Concerning the right Use of the Fathers," which is characterized as "a very strong chain of arguments that form a moral demonstration against those who would have differences in religion to be decided by the authority of the fathers." 2. "An Apology for the reformed Churches," &c. in which he vindicated them from the charge of schism brought against them by the advocates of the Romish church; and, 3. "An Apology for the Synods of Alençon and Charenton." The first two were translated into the English and Latin languages, and enjoyed a very high reputation; the last gave rise to a bitter controversy, which injured the fame of all the parties engaged in it. Bayle. Moreri.

DAINUR, in *Geography*, a town of Persia, in the province of Irak-Agemi; 50 miles W. of Amadan.

DAJON, a town of Africa, in the country of Agonna.

DAIRA, in *Mythology*, one of the Oceanides, mother of Eleusis, by Mercury.

DAIRI, or Dairo, in the *History of Japan*, is the sovereign pontiff of the Japanese; or, according to Kæmpfer, the hereditary ecclesiastical monarch of Japan. In effect, the empire of Japan is at present under two sovereigns, *viz.* an ecclesiastical one, called the *dairo*, and a secular one, who bears the title of *kubo*. The last is the emperor, and the former the oracle of the religion of the country. See Japan.

DAIRIER, in *Rural Economy*, a name sometimes applied to the person who keeps a dairy, or a dairy-man.

DAIR-KARRAN, in *Geography*, a town of Asiatic Turkey, in the province of Kurdistan; 30 miles S.S.E. of Kerkuk.

DAIRY, in *Rural Economy*, a name sometimes applied to the different sorts of products of this kind, and sometimes to the place where milk, butter, and cheese, are laid up and preserved; hence these repositories are further distinguished into butter, cheese, and milk dairies, according as one or other of these articles constitutes the principal object of the dairy-farmer. It has been remarked by a late partial writer, that there are some sorts of grass lands that answer better in this management than others. It is not, he says, well decided, though general experience seems to favour the opinion, that the very fertile pasture lands may be more profitably applied to the purpose of grazing or fattening animals, than that of the dairy; but such as are not capable of bring-

ing the larger ſorts of cattle to a complete ſtate of fatneſs, and which uſually let from twenty to five-and-twenty ſhillings the acre, may be more profitably employed in this way. And that moſt of the low and more moiſt kinds of meadow lands, which, though the value may be high, as they do not ſucceed ſo well for the purpoſe of fattening, may be found highly uſeful under the dairy ſyſtem. The high, open, and expoſed uplands are always, he conceives, leſs proper for this ſort of practice, than thoſe which are ſituated lower, and which are more encloſed and warm. It is added, that in this buſineſs the nature of the paſtures and other ſorts of food which the farmer has at command, muſt chiefly direct him in the extent and kind of dairy which he is to purſue. Where the graſs lands are of the older kinds, and tolerably rich and fertile, butter ſhould probably, in general, he thinks, be the principal object; but where they have been more recently converted to the ſtate of ſward, and are of a more cool as well as leſs rich quality, cheeſe may be the moſt depended upon. It is, perhaps, ſays he, only under particular circumſtances and ſituations that the different methods or modes of dairying can be profitably and conveniently combined or carried on together. Some ſituations, however, admit of it with very conſiderable advantage.

It is an obſervation, ſanctioned by long experience in this ſort of management, in the midland diſtricts, that grounds which have been for a great length of time in the ſtate of paſture, are capable of affording milk which abound more in the oily principle, or that of cream, while thoſe which have been laid down to ſward for a ſhorter period, and are of a more moiſt, cold quality, are more productive in ſuch milk as has the caſeous or curdy material in a large proportion in compariſon to that of the cream. And which the practice of the Yorkſhire dairy-farmers ſtill further confirm, by being much in the habit of preſerving their old paſtures in their original ſtate, in conſequence of their finding that the milk which is produced from them is churned with much greater facility, and the butter capable of being kept in a better manner, than where ſuch naturally rich grounds are improved by tillage. It has been ſtated that much difficulty has been found, not only in the making, but the keeping of the butter, eſpecially in the warmer months, in thoſe caſes where the land had been broken up by tillage, and rendered more rich, by the application of manure, eſpecially that of the calcareous deſcription, where, while in the natural ſtate, there were not the ſmalleſt difficulties of this nature, the butter being of the fineſt quality. From which a concluſion is drawn, that old paſtures have in addition to the property of the oily or bituminous matter being ſupplied in larger proportion, that of rendering the butter more firm and waxy in its quality. It has likewiſe been noticed by an able writer, that in the highlands of Scotland the richneſs of the butter has been univerſally aſcribed to the cows feeding upon the old graſs in the remote glens; though it is hinted that this may partially depend on the manner in which it is made. In Cheſhire the inferior ſorts of paſture lands are likewiſe ſtated by the author of the "Six Months Tour" as being there found the moſt proper for the purpoſe of making cheeſe. However, though this may be the caſe in a certain degree, there cannot be any diſpute, but that excellent butter may be made in many ſituations, where the paſtures are comparatively new, and even where they have been but lately laid down to the ſtate of graſs; as well as that cheeſe of a good quality may be produced where the ground, uſed as paſtures, has been long in the ſtate of ſward or old herbage. Indeed later experience ſeems to have ſhewn that butter, equally good and rich in quality with that produced on the old fertile paſtures, has been afforded while the cows were foddered in the ſtalls on cut clover, rye-graſs, and other ſorts of green food.

The deterioration of land for the purpoſe of the cheeſe dairy, by the application of ſuch ſubſtances of the manure kind as have a tendency to render it more fertile, as by the uſe of dung, or ſheep feeding, &c.; is ſuppoſed by Mr. Rudge, in his Survey of Glouceſterſhire, to be probably owing to the introduction of ſuch plants as did not grow there before, or the deſtruction of ſome that did. "The cauſe does not," ſays he, "originate with the cow, but the herbage on which ſhe feeds. The ſame cow, on two paſtures ſeparated only by a hedge, will give milk of different qualities; from one ſhall be made fine, rich, and cloſe cheeſe; while from the other ſhall be made rank, "heaving," hollow, unpleaſant to the palate, and unfit for the market."

It is further ſtated on this curious and intereſting ſubject by the ſame writer, that "in the pariſh of Haresfield, two grounds adjoining each other were alternately uſed for the paſture of cows; while they were on one, excellent cheeſe was made, but on the other, it was difficult to make any tolerably good. The latter had been lately well dreſſed with manure which produced plants unfavourable to the dairy; and the dairy-woman herſelf remarked, that if the farmer continued to enrich the herbage with dung, ſhe muſt give up making." This ſuggeſts ſome circumſtances which ſhould be regarded in the regulation of cow paſtures, but which will be noticed in ſpeaking of dairy management. See DAIRYING.

It is ſuppoſed that, "among the plants which are uſeleſs or unfavourable to the making of good cheeſe, are the following; the white honey-ſuckle *(trifolium repens)*, the different kinds of crow-foot *(ranunculus)*, and wild garlic *(allium ampeloprafum)*, &c." The "white honey-ſuckle is brought forward by manure and ſheep-ſtock," and is "a proof of good land, at leaſt of land in a ſtate of high cultivation, and hence has a tendency to raiſe the quality of the milk and make the cheeſe heave." But that "all the ſpecies of crow-foot "crazeys," or "butter cups," except the ſweet wood crow-foot (as it is ſaid, found only in woods), are uſeleſs, if not noxious. However their bloſſoms may add to the beauty of the herbage, or give an apparent richneſs to the paſture, the milk is not," the writer ſays, "indebted to them for colour, as is ſometimes ſuppoſed, ſince the cows never crop them, if they can avoid it." See CRAZEY and CROW-FOOT.

The garlic, which is "common in ſome meadows, gives a diſagreeable flavour to butter and cheeſe; and it does not appear that cows much diſlike or refuſe eating it; perhaps in conſequence of its being ſo much blended with the graſs, they cannot help cropping a little." And in the autumn, "the decayed leaves, particularly of the aſh tree, communicate a rank and bitter taſte to milk; when theſe, therefore, cover the ground, it is adviſeable either to keep the cows in the yard, or, what is better, to rake the leaves off the paſture to the dungheap."

The poiſonous quality of the leaves of the yew tree ſhould conſtantly prevent its being grown in or even near to ſuch grounds as are uſed for cow paſtures.

It has been remarked by doctor Anderſon, that there is no ſet of experiments, which can be depended upon with any degree of certainty, whether the butter or cheeſe dairy is capable of affording the better profit to the farmer, in caſes where the management is equally judicious and proper. It is however ſuggeſted, that, in each caſe, the moſt valuable part of the milk is converted into an article of great uſe and importance as food; and that though the former may afford

a con-

a conſiderably higher price than the latter in the market, yet from the great difference in the quantity of the products, in the expence and trouble in the management, and in various other circumſtances, it would ſeem that the real advantages are nearly equal. It has been ſtated, he obſerves, previouſly to the late great riſe in the prices of theſe different articles, to amount, whether of butter and butter-milk, or of cheeſe and whey, to nearly four-pence half-penny for each gallon of milk; which at preſent is perhaps little leſs than from ſix-pence to ſix-pence half-penny or ſeven-pence. It is however ſuppoſed, that in the neighbourhood of large towns, and other places where the demand for butter is conſtantly extenſive, it may be more profitable to have a butter-dairy than one of the cheeſe kind. But in all caſes of this nature much muſt depend, in reſpect to profit and advantage, on the care and exactneſs of the management which is employed in conducting the buſineſs. See DAIRYING.

It has been ſuggeſted, in an intereſting paper in the fifth volume of "Letters and Papers of the Bath Agricultural Society," that when a dairy is eſtabliſhed, the undertaker may ſometimes think it his intereſt to obtain the greateſt poſſible quantity of produce, ſometimes it may be more beneficial for him to have it of the firſt quality, and at other times it may be neceſſary to have both theſe objects in view, the one or the other in a greater or leſs proportion; it is conſequently of importance that he ſhould know how he may accompliſh the one or the other of theſe purpoſes, in the eaſieſt and moſt direct manner. To be able to convert his milk to the higheſt poſſible profit in every caſe, he ought to be fully acquainted with every circumſtance reſpecting the manufacture of butter as well as of cheeſe; and it may in ſome caſes happen that a certain portion of that milk may be more advantageouſly made into butter than into cheeſe, while another portion of it would return more profit, if made into cheeſe. See DAIRYING.

In ſhort, the conſequence and the credit of the dairy muſt, under all circumſtances, principally depend on the neatneſs of the management which is purſued, every part being kept perfectly clean, ſweet, and in order, the floors being regularly rendered cool, by frequent waſhing with cold water, and the various utenſils well cleaned and ſcalded after every time of being uſed.

DAIRY-*Farm*, in *Agriculture*, is that ſort of farm which is chiefly of the graſs-land kind, conſiſting of meadow and paſture, with but little of the ground in the ſtate of tillage; in which the profit of the farmer principally depends upon the dairy. In Cheſhire, Glouceſterſhire, Wiltſhire, Buckinghamſhire, and ſome of the midland diſtricts, as well as in ſome parts of Eſſex, Cambridge, Suffolk, and the county of Dorſet, &c. there are extenſive farms of this nature. In moſt, if not all farms of this deſcription, there ſhould, however, always be a portion of the land under the ſtate of tillage, in order that a ſufficiency of grain, and ſtraw for litter, may be provided for the teams, and at the ſame time green cattle crops be raiſed in due proportion to the number of cows which are kept, as it has been lately ſhewn that in this way the dairy farmer may derive conſiderably more profit and advantage than in the uſual old method of management. See DAIRYING.

It is ſtated by Mr. Holland, that "the more general introduction of green crops, and of the practice of ſtall feeding for dairy cows, may certainly be reckoned among the moſt conſiderable improvements which have taken place of late years in the agriculture of Cheſhire. With the dairy-farmer," ſays he, "it is a principal object to increaſe the quantity of his milk, and to continue it as long as poſſible. This can in no way be more effectually done than by giving green food to his cattle; and he is informed by ſeveral intelligent farmers, that by this management the milk may be continued a month longer in the autumn than could be effected by truſting to the paſtures only for a ſupply of food." It is therefore conceived, that the importance of this circumſtance in a dairy diſtrict muſt be ſufficiently evident to every one who has in the leaſt degree attended to it. And the reſults of the ingenious experimental trials of Mr. C. Curwen in keeping milch cows in this way, with the view of affording milk in the winter ſeaſon, have placed the benefits to be derived from it in ſo clear a point of view, that there cannot be the leaſt difficulty or doubt concerning it. See DAIRYING.

DAIRY-*Houſe*, in *Rural Economy*, a building or place erected for the purpoſe of carrying on the buſineſs of dairying. Theſe ſorts of buildings ſhould conſtantly be ſituated and diſtributed in ſuch a manner, in reſpect to the other farm-offices, as that labour may be abridged as much as poſſible, and the greateſt poſſible convenience be obtained, while a due temperature is preſerved in them. The chief points to be aimed at, in order to accompliſh theſe objects, are thoſe, of having them ſufficiently near the ſheds or cow-ſtandings, that the milk may be readily conveyed to them; the form being ſuch as to combine well with the nature of the other erections; the door or entrance into the room deſtined for the milk, being made through that of the ſcalding room, which ſhould have the copper for heating water and other purpoſes placed in a ſhed without it, that the heat may be kept at as great a diſtance as poſſible from the milk, a cock being fixed in the bottom of it, for conveying the heated water through a trough or pipe acroſs the ſcalding room, in which another cock ſhould be fixed, for the convenience of waſhing ſmaller utenſils, paſſing the wall into the milk-leads, pans, trays, or coolers, that whenever they are required to be ſcalded, the boiling water may at once paſs through the whole range of them, or be detained at pleaſure in any one of them, ſo as to effect the buſineſs in the moſt complete and perfect manner, being afterwards taken off by a ſuitable drain made for the purpoſe. The paſſage for the water, through the wall of the dairy, ſhould be in a trough of ſufficient dimenſions to admit the diſcharging of a pailful of milk into it with perfect ſafety, having a hair ſieve ſo placed in it as that the whole of the milk of the cows may be made to paſs through it into the neceſſary trays or coolers in which it is to ſtand; as by this ſimple contrivance, the neceſſity of dirty men or boys entering the dairy-houſe is wholly prevented. There ſhould likewiſe be a trough, pipe, or ſome other ſimilar contrivance, for the purpoſe of conveying the waſte milk, whey, &c. from the dairy-houſe to the ciſterns for containing the waſh for the pigs. Theſe conveniences have many of them been ſuggeſted by Mr. Young in his excellent "Calendar of Huſbandry."

Where theſe buildings are intended to become objects of ornament, and expence is not regarded, ſituations ſhould be ſelected ſo as that the effects of them may be the moſt pleaſing and complete.

The regulation of temperature may be accompliſhed either on the plan ſuggeſted by doctor Anderſon, of having double walls and roofs; or by means of hollow walls; and for common purpoſes, by the walls having a vacuity left, of eight or ten inches in width, between the lath and plaſter, as ſuggeſted by Mr. London in his "Treatiſe on Country Reſidences." Where a ſpring, fountain, or *jet d'eau* can be ſo contrived as to break or burſt forth, in the centre of the principal room or apartment, it will not only afford a highly agreeable effect, but be of great convenience to the perſon who has the management of the buſineſs of the dairy.

In farm-dairies, it is neceſſary for the buildings to vary according

cording to the nature of the dairy buſineſs to be carried on in them, as whether they are uſed for butter, cheeſe, or milk; and the ſizes of them ſhould be regulated by the number of cows which are to be kept. In the Glouceſter dairy-houſes twenty feet by ſixteen are the uſual dimenſions for forty cows; and thirty feet by forty, for one hundred cows.

A well-conſtructed butter-dairy ſhould conſiſt of three rooms, or apartments; namely, a milk-room, a churning-room, with neceſſary apparatus; and a room for the different utenſils, and the cleaning and airing them in, when it may be requiſite.

The cheeſe-dairy ſhould in the ſame manner be conſtituted of three rooms; one for the reception of the milk; another for the ſcalding and preſſing of the cheeſe; and a third for the purpoſe of ſalting it in. And in addition, there ought to be a room for the ſtowing of the cheeſe, which may conveniently be a loft made over the dairy. It is frequently at a diſtance, which is inconvenient and troubleſome.

The milk-dairy only requires two good rooms, one for the reception of the milk; and another for the purpoſe of ſerving it out in, and that of ſcalding, cleaning, and airing the different utenſils.

It is utterly impoſſible to conduct the dairy buſineſs with propriety and due advantage, except where a place ſuitable for preſerving the milk, and for performing the various operations in, be firſt provided. In order that an equable temperature may prevail at all ſeaſons of the year in this ſort of building, a northern expoſure has been ſuggeſted as the moſt proper, and which ſhould be dry and near a ſpring or running water, that it may be rendered clean and ſweet at all periods without difficulty. And where it is ſo ſituated, as that the action of the ſun upon its roof and walls can be prevented by the ſhade of trees or buildings, it is a circumſtance of much importance to the ſucceſs of the buſineſs.

From the general difficulty of obtaining theſe different requiſites in the farm-houſe, it has been recommended that a detached building ſhould be erected or converted to the purpoſe. This need not, however, be the caſe where there is already a proper convenience, or an old erection that can be altered with facility, ſo as to anſwer the intention.

The plan which a writer, who has beſtowed much attention upon the ſubject, has propoſed, is, that it ſhould be conſtructed in a ſort of range of narrow buildings, as ſhewn in the ground plan at *fig.* 1. in *Plate* XII. of *Agriculture*, in which the middle diviſion, A, is the proper milk-houſe or room; that ſhewn at B, is intended to ſerve as a room for cleaning, and laying up the different neceſſary utenſils in; and that at C, is deſigned as a ſtore-room, in which the cured butter, and various other products, as well as the ſpare dairy utenſils, may be ſecurely kept, by being locked up. Near large towns it might alſo be employed as a place for keeping ice in, by being properly fitted up for the purpoſe. In cheeſe-dairies another room would be neceſſary for the purpoſe of ſalting and preſſing; which might be added at either end, as moſt convenient.

It is adviſed that the walls of the middle diviſion ſhould be conſtructed of brick, or ſtone and lime, all round on the inſide, but which need not be more in thickneſs than one brick in length, where that ſort of material is uſed, or one foot in the caſe of ſtone being employed; but the wall beyond this, which ſhould be full ſix feet in thickneſs, may be formed of ſod on the outſide, being well rammed with earth within, ſo as to fill up the ſpace between the two walls. The firſt or inſide wall of this compartment may be raiſed ſeven, eight, or more feet in height on the ſides upon which the roof may be reared, where a loft above is not wanted, the end walls being carried up to the full height of the roof. The beſt covering for the roof in this caſe, is ſuppoſed to be reed or thatch, which ſhould not be leſs than three feet in thickneſs, being carried downwards ſo as to cover the whole of the walls on each ſide; but where theſe materials are not in plenty, they need not be applied to quite ſo great a thickneſs. A wooden pipe ſhould be fixed through the roof, exactly above the middle of the building, having ſufficient length to riſe a foot or more above it, which may occaſionally ſerve as a ventilator. The top of it ſhould be covered ſo as to prevent rain from getting through it, having a valve ſo fixed in it, as to be capable of being opened or ſhut at pleaſure by means of a cord from below. There ſhould likewiſe be a window on one ſide for the admiſſion of light, which ſhould be conſtructed in the manner ſhewn at F G, *fig.* 2, in the ſection of the building. And this opening ſhould be cloſed by means of two glazed frames, one on the outſide at G, and the other on the inſide at F, which, together with the great thickneſs of the walls, the thatch of the roof, and of the buildings at the end, contributes to render the temperature of the room more equable at the different ſeaſons of the year, by more effectually preventing the influence of the external air upon it. The ſmall ſpaces or apartments ſhewn at R, S, are ſimply cavities formed in the thickneſs of the partition walls, which may be employed for any uſe that may be convenient; the double doors in the paſſages being deſigned wholly for cutting off more perfectly all communication between the external air and the milk-room, when either the great heat or exceſſive coldneſs of it may render it neceſſary. The thatch above theſe ſmall ſpaces, or rooms, ſhould come one foot lower within than in the milk-room, in order more fully to prevent all communication of air from the outer apartments at the place where the couples for the roof are placed. At periods when the ſtate of the air is temperate, the door at T may be generally left open to facilitate the entry to and from the milk-room, for common purpoſes. All the doors open as ſhewn by the dotted lines: and through each of theſe doors, as well as the outer doors of the rooms or apartments, B and C, an aperture or opening ſhould be made of about a foot ſquare, having a ſmall door exactly fitted to it, which can be opened and ſhut at pleaſure. Likewiſe over the whole of the inſide of each of theſe apartments, a piece of fine gauze ſhould be ſtretched, being covered with a fine netting of wire, ſo that when the air is temperate, and the wind blows in a proper direction, by opening theſe little doors, a draught or current of air may be carried through the whole of theſe buildings, which will keep them ſweet and dry, without admitting flies or other vermin. The whole of theſe apartments ſhould be neatly plaſtered, with lime on the inſide of the walls and ceiling. Likewiſe the apartment A, at leaſt, ſhould be paved with flat ſtones, which ſhould be raiſed ſix inches higher than the ſurface of the ground without, having ſlanting gutters made to convey away readily water or any other liquid which may be accidentally ſpilled. The walls quite round ſhould be lined with ſhelves of a convenient breadth, in ranges, one above another, on which the diſhes may be placed; and a large table ſhould ſtand in the middle, as ſhewn by the dotted lines in the plan; which, if made of ſtone, is the moſt cleanly and convenient of any ſort of material. Beneath it a piece of the pavement, about a foot in breadth, ſhould be raiſed ſix inches higher all round than the level of the floor, ſo as to form a ſort of trough or ciſtern within it for holding water. This trough or baſon ſhould be capable of being wholly emptied at pleaſure by means of a plug fixed in a hole which opens into and admits the water to be diſcharged into the common gutters.

The cleaning and repoſitory room ſhould be fitted up, by having

having ranges of ſhelves placed all round the walls, as well as tables and other neceſſary furniture put where they may be requiſite. In this the walls may be thinner than in the other caſe, and be wholly built of brick or ſtone, the thatch being likewiſe leſs thickly applied. There ſhould be ſet up in one corner a boiler, or cauldron, of ſufficient ſize for the dairy, for the purpoſe of heating the water for ſcalding the veſſels, being placed over a cloſe furnace, the flue of which ſhould be made to terminate in a chimney carried in a ſlanting manner over the door in the gable end above which it riſes, ſo as to afford a paſſage to diſcharge the ſmoke. This boiler is ſhewn at H, in *fig.* 1.

The third diviſion, or room, may be made uſe of for different purpoſes, as ſuggeſted above; but where ice is to be preſerved in it for the ſummer, which may often be found advantageous to the dairy, the walls ſhould be built in the ſame manner, and of the ſame materials, as thoſe in the firſt diviſion, or that marked A, as ſhewn by the dotted lines *i, k, l, m*; the thatch or reed being applied in the ſame thickneſs. And in this caſe there ſhould be firm poſts of wood placed in the floor, in the manner as ſhewn at *n, o, p, q*, ſo as to form a ſort of inner ſquare, with an open walk all round of two feet in breadth; wicker-work hurdles of a proper ſhape ſhould be placed within theſe poſts, being wholly compoſed of peeled wands, which have been previouſly dipped in coal-tar in a warm ſtate, in order to preſerve them from decay. The receptacle for containing the ice, being within this ſquare, is capable of being filled from the double doors at K L, by opening them at the time, and immediately cloſing them again, not to be reopened till the period of its being again neceſſary to fill it; the aperture between the doors being filled with ſtraw rammed ſo as to become firm, and thereby prevent the admiſſion of air. The ice ſhould be taken out as it may be wanted, by paſſing through the middle diviſion, or milk-houſe. Various advantages and conveniences, it is ſuppoſed, would attend this accommodation and contrivance, and the expence at the ſame time be but trifling. In this manner the products of the dairy would conſtantly be capable of being cooled to that degree, in the ſummer ſeaſon, which ſhould be found to give them their greateſt perfection. And the attentive and ingenious dairy-farmer would find ſuch an accommodation capable of other beneficial applications.

It is obvious that all the contrivances of this dairy-houſe, as deſcribed above, are ſolely intended to enable the careful dairy-farmer to preſerve his milk in a proper temperature in the ſummer as well as the winter ſeaſon, with the leaſt poſſible trouble and expence to himſelf; as it is well known, that any conſiderable variation in the degree of heat has a great tendency to derange the operations of the dairy, and conſequently to diminiſh the value of the products of it. It is found by experience, that if the heat be too great, the milk ſuddenly coagulates, without admitting of any ſeparation of the cream; and it becomes ſo ſuddenly ſour as to greatly injure every operation. While, on the contrary, when the milk is kept in too cold a temperature, the cream ſeparates from it in a ſlow manner, and with difficulty, acquiring a bitter diſagreeable taſte, the butter being ſcarcely able to be made to come at all; and when obtained, is of ſo pale a colour, ſo ſmall in quantity, ſo poor to the taſte, hard and brittle in its conſiſtence, and in every reſpect of ſo little value, as to bring a very low price at the market, in compariſon to what it would have produced had it been preſerved in a proper degree of warmth. In order, therefore, to avoid theſe different extremes as much as poſſible, the milk properly ſo called is, in this form of dairy-houſe, depoſited in the centre of the building, into which there is no direct acceſs immediately from the open air; nor even from the porch, except through double doors, one of which ſhould conſtantly be ſhut before the other is opened, whenever either the heat or coldneſs of the weather is exceſſive; but under other circumſtances, this precaution may be overlooked. The walls which encloſe this part of the building, being formed of ſuch a thickneſs, and of ſuch earthy materials, as well as the roof ſo thickly covered with thatch, as theſe ſubſtances are found to tranſmit heat and cold with leſs facility than any others, which can be eaſily had, conſequently a long continuance of either hot or cold weather could have no ſenſible effect in altering the temperature of this room or diviſion; and if it ſhould at any time acquire a ſmall degree of heat or cold more than was proper, and this were corrected by artificial means, it would retain that artificial temperature for a long time. Theſe are the principal objects deſigned to be acquired by this conſtruction of dairy-houſe.

The ingenious inventor further remarks, that from fifty to fifty-five degrees of heat on Fahrenheit's ſcale is about the average temperature that a building, conſtructed in the manner of the above, would naturally preſerve at all ſeaſons of the year in this climate, if not affected by external objects. But that, as the heat of the milk, if in conſiderable quantities, would tend in ſummer to alter the temperature of the air, there is no improbability but that it might in ſome caſes be raiſed in this way to a much higher degree than was proper. Therefore, as a convenient remedy for this inconvenience, the aſſiſtance of the ice-houſe has been had recourſe to, as by having a ſmall quantity of ice placed in the milk-room, when neceſſary, the heat may be quickly brought to the proper ſtate. In the two ſmall chambers adjoining the ice-houſe, or in the paſſage around it, the butter may be depoſited, and preſerved in a much cooler ſtate than even in the milk-room. Beſides this, other benefits may be derived from this additional diviſion of the building. It is likewiſe ſuggeſted, that if the cold ſhould ever become too great in the winter ſeaſon, it might be remedied either by means of a barrel of hot water, cloſely bunged up, being placed upon the table of the milk-houſe, and ſuffered to remain till it cools, or by having hot bricks laid down for the ſame purpoſe; which are much preferable to any kind of chaffing-diſh with burning embers in it, as preventing more certainly a bad taſte being communicated to the milk.

But dairy-houſes may be contrived and conſtructed on various other more ſimple and cheap forms; the ground plan and internal parts of one of which may be ſeen at *fig.* 3. in the ſame plate, in which A is the milk-houſe or room, the coolers for containing the milk being ſhewn at *a, a, a*; *b*, the ſlab for depoſiting the butter upon, when made up; *c, c, c*, the cocks for drawing off the milk from the coolers, one of which is ſo contrived as to ſerve two coolers, by having a ſhort piece of leaden pipe from the holes *o, o, o*, which are ſtopped by the plug *p*, made ſufficiently long to reach above the ſurface of the milk; *d*, a large cock, by means of which water can be thrown upon the floor, which is made to ſlope a little from that part; *e, e, e*, are likewiſe cocks fixed at the back parts of the coolers, for the purpoſe of letting in water; *f*, the door, which is latticed in the manner ſhewn at *fig.* 4; *g*, another door, which is commonly made uſe of, but which is made with pannels.

The churning-room is ſhewn at B, in which *h* is the fire-place; *k*, a boiler; and *l*, a large copper, which may be employed for the purpoſe of brewing.

The room for the purpoſe of airing and drying the different ſorts of dairy-utenſils is ſeen at C; and which may likewiſe

wiſe be made uſe of occaſionally as a laundry: over the whole of theſe rooms, apartments for lodging the ſervants may be made with much convenience, where they may be neceſſary.

At *fig.* 5. is given an inſide view of the milk-room of this dairy, at the end Q.

An ingenious dairy-farmer near Liverpool (Mr. Wakefield) has his dairy-houſe conſtructed on this plan, which he finds to anſwer well, and be convenient.

It has been obſerved by Mr. Marſhall, that the rooms of the Wiltſhire dairy-houſes have commonly outer doors, which often open under a ſort of pent-houſe, or incloſed lean-to ſhed; which he conſiders as convenient, and beneficial in affording ſhade and ſhelter, as well as a degree of coolneſs to the whole dairy building. And in particular caſes double doors are had recourſe to, the inſide one being cloſe-boarded, and that on the outſide open-paled, ſomewhat in the manner of a common gate; in this way air is not only freely admitted when the weather is cloſe and warm, but at the ſame time dogs, poultry, &c. guarded againſt. This he thinks an improvement which in all caſes would be of great advantage in the ſummer ſeaſon.

Another conſtruction of farm dairy-houſe which is found uſeful, is ſhewn at *figs.* 6 and 7, in the ſame plate.

Beſides theſe ſorts of dairies, there are others which are chiefly contrived as ornamental buildings, and at the ſame time to be employed for the purpoſe of preſerving milk and butter, in attachment to country reſidences. Theſe ſhould always be planned and contrived with proper taſte, according to the nature and ſituation of the particular place on which they are to be erected, and the circumſtances which regard their management; being careful that they have a ſufficient protection from too much heat in the ſummer ſeaſon.

At *figs.* 1 and 2, in *Plate* XIII. is repreſented an elegant dairy-houſe of this kind, taken from that of his grace the duke of Bedford's, at Woburn Abbey.

DAIRY-*Huſbandry*, is that kind of farm-management which principally relates to the buſineſs of dairying. It is a ſort of huſbandry which is practiſed in ſome of its branches in either a greater or leſs degree, in almoſt every diſtrict of the kingdom; though there are but few in which it has attained to any very high ſtate of excellence. So far as the buſineſs of cheeſe-making is concerned, Cheſhire, Glouceſterſhire, and Wiltſhire, in the ſouthern parts of the iſland, and Ayrſhire in the more northern, are the moſt diſtinguiſhed; while the counties of Eſſex, Cambridge, Dorſet, and Suffolk, are thoſe which are the moſt celebrated for the quality and quantity of their butter. In the northern part of the country, with the exception of the diſtrict noticed above, Mr. Donaldſon conſiders this ſort of huſbandry as ſtill but in its infancy. In order to the carrying on of this kind of huſbandry with full effect and advantage, a ſufficiency of room in the dairy-houſe, for the convenience of performing all the various operations without embarraſſment, in proportion to the number of cows, is eſſential. And beſides this, great knowledge and ſkill in the management, with much attention to cleanlineſs, are requiſite. It has been remarked by the writer already mentioned, that whoever has attended to the operations carried on in a well-conducted buſineſs of this nature, even for a ſhort time, muſt have been ſatisfied that ſkill was as requiſite in the perſon who directed, as attention and alertneſs in thoſe who executed them. In fact, he thinks, it muſt have been evident, that without a knowledge of the beſt modes proper to be adopted, under different circumſtances, and a regularity, method, and prompt attention to their execution, buſineſs of this kind muſt ſoon go into the utmoſt confuſion and diſorder.

In the moſt modern and improved manner of performing this ſort of buſineſs, much regard is likewiſe neceſſary in the farmer to the abundant cultivation of the moſt proper and uſeful kinds of crops of the green ſort, for the food of the cows. See DAIRYING.

DAIRY-*Leaſe*, in *Agriculture*, is that ſort of covenant or agreement under which lands in ſome diſtricts are let, for the purpoſe of being conducted under the dairy ſyſtem. Leaſes of this kind are common in Dorſetſhire and ſome other counties. See LEASE.

DAIRY-*Maid*, in *Rural Economy*, a name applied to the woman who has the chief management of a dairy. This ſort of perſon ſhould always be perfectly regular and ſteady, and at the ſame time fully converſant with all the various proceſſes which are neceſſary to be performed in managing the buſineſs. She is ſometimes denominated dairy-woman. See DAIRYING.

DAIRY-*Man*, a name frequently applied to ſuch men as have dairy-farms, or who are extenſively engaged in the dairy buſineſs.

DAIRY-*Utenſils*, are all ſuch kinds of implements as are employed in the operations of the dairy. It is adviſed by an excellent writer, that, from their uſe, they ſhould in general be made of wood. Though lately, ſome, from an affectation of a ſuperior degree of neatneſs and elegance, have had recourſe to veſſels which are formed of lead or of common earthen-ware, for different uſes in the dairy. But that, as the acid of the milk is found to be capable of decompoſing and diſſolving a portion of lead, braſs, or copper, and with theſe of forming a compound of a poiſonous nature, ſuch ſorts of veſſels muſt be highly pernicious in the buſineſs of the dairy, and of courſe ſhould be baniſhed from ſuch ſituations. And this is equally neceſſary with reſpect to any of the common ſorts of earthen-ware, which, from their being glazed with lead, and the glazing being ſoluble in this ſort of acid, are improper in the ſame degree. It is likewiſe ſuggeſted that caſt-iron has been recommended as a proper ſubſtitute for theſe; but as this metal is alſo ſoluble in the acid of milk, though the ſolution be not poiſonous, yet, as it may affect the taſte of the products of the dairy, and render their qualities different from what they would have naturally been, veſſels of this kind ſhould likewiſe be ſet aſide. In fact, excepting veſſels of true porcelain, or glaſs, which are much too expenſive, it is ſuppoſed there are none that can with propriety be ſubſtituted for wooden ones in this intention. It is obvious that neither china nor glaſs veſſels can ever come into general uſe for dairy purpoſes; nor is it neceſſary for the dairy-farmer to think of any other ſort of diſhes for his milk than thoſe of wood; as theſe, when properly managed, can be kept as clean and ſweet as is needful for ſuch veſſels. This circumſtance is indeed ſo well underſtood, that wooden dairy utenſils are almoſt in general uſe through the whole country, and can of courſe be readily procured in almoſt every ſituation, of ſuch qualities, forms, and conſtructions, as may be the moſt proper under the particular circumſtances of the caſes.

It has lately been found that ſlate is an uſeful material for the purpoſe of making milk coolers, and in ſome of the midland diſtricts the common flag ſlate has been employed in this way. The better ſorts would ſeem, however, to be the moſt proper.

The moſt material utenſils for the purpoſes of the dairy-farmer are milk-ſkeels or creaming-diſhes, milk-pails, milk-cowls or coolers, milk-ſtrainers or ſieves, cheeſe-ladders, lading-diſhes, ſkimming-diſhes, churns, cheeſe-vats and cheeſe-preſſes; the expences of which muſt evidently vary

in

in different ſituations, but in the county of Glouceſter they are ſtated to be as below:

	£	s.	d.
Cheeſe-tub or cowl	1	10	0
Milk-bowl and ſieve	0	3	0
Barrel-churn, iron work and ſtand	2	12	0
Common barrel-churn	2	10	0
Harland's improved barrel-churn	5	5	0
Set of vats, lined with lead	3	3	0
Or, which is better:			
Whey-ſkeel	1	1	0
Milk-ſkeel	0	8	4
Milk pail	0	6	8
Butter-ſkeel	0	5	0
Cheeſe vat	0	3	0
Lade-bucket, or ("gawn") gallon	0	1	6
Skimming-diſh	0	0	10
Pair of butter-ſcales	0	3	0
Braſs pot for warming milk in	2	0	0
Cheeſe-preſs and cloths	10	10	0

Conſequently a ſet of this ſort of utenſils, with one churn, will amount to about twenty or twenty-two pounds; but for a dairy of eighteen or twenty cows, a greater number of ſeveral of the articles will be required, as two whey-ſkeels, three milk-ſkeels, three milk-pails, ſix cheeſe-vats, and two butter-ſkeels.

DAIRYING, the art of making cheeſe, butter, and other dairy products. This is a ſort of management which is only adapted to particular ſituations and circumſtances. See DAIRY.

It has been obſerved as plain and deciſive, "that much of the profit, in this ſort of management, muſt conſtantly depend upon the care and aſſiduity that is beſtowed in conducting the different proceſſes of the buſineſs." And that "it ſhould only be undertaken by thoſe who are capable of paying the moſt minute attention to every department of it; as, unleſs this becomes a fixed and eſtabliſhed principle in the farmer's mind, the chance of ſucceſs is precarious and uncertain. To truſt wholly to common ſervants, in this ſort of buſineſs, is always hazardous, and never to be practiſed where it is carried on to any extent."

The firſt thing to be attended to in an undertaking of this nature is, to chooſe cows of a proper ſort, according to the mode of dairying which is to be practiſed. Among this claſs of animals it is found, by experience, that ſome kinds give milk of a much thicker conſiſtence and richer quality than others; nor is this richneſs of quality neceſſarily connected with the ſmallneſs of the quantity yielded by cows of nearly an equal ſize; it therefore behoves the owner of a dairy to be peculiarly attentive to this circumſtance. In judging of the value of a cow for the purpoſe of the butter dairy, it ought rather to be the quantity and the quality of the cream produced from the milk of her in a given time, than the quantity of the milk itſelf, that ſhould determine the farmer. This is a circumſtance that will be ſhewn in future to be of more importance than is generally imagined: but where cheeſe is the main object, both the quality and proportion ſhould be conſidered. The ſmall cows of the Alderney breed afford the richeſt milk hitherto known; but individual cows in every county may be found, by a careful ſelection, that afford much thicker milk than others; theſe therefore ought to be ſearched for with care, and their breed reared with attention, as being particularly valuable in the intentions of the dairy farmer.

It has been remarked, by an able practical writer, that on "comparing the milk of two cows, in order to judge of their reſpective qualities, particular attention ſhould be paid to the time that has elapſed ſince their calving; as the milk of the ſame cow is always thinner ſoon after calving than it is afterwards, as it gradually becomes thicker, though generally leſs in quantity, in proportion to the time the cow has calved. The colour of the milk, however, ſoon after calving, is richer than it afterwards becomes; but this, eſpecially for the firſt two weeks, is a faulty colour that ought not to be regarded."

The next thing that is neceſſary in this ſort of management is that of being provided with a ſufficiently large and convenient dairy-houſe, whether the object be cheeſe or butter. It ſhould be ſo proportioned to the number of cows, as that there may be ſufficient convenience for performing all the neceſſary operations without embarraſſment; and much attention muſt be paid to cleanlineſs in every thing that relates to it, ſuch as the ſhelves, floors, and different implements which are made uſe of, by daily ſcalding, ſcrubbing, rinſing, and drying, in order to prevent any ſort of acidity taking place; as, without due regard in theſe reſpects, it is impoſſible that the produce can be of ſuperior quality, or ſuch as will keep ſweet and good for any length of time, &c. Cleanlineſs may indeed, ſays Mr. Donaldſon, be ſaid not only to be neceſſary in dairy-huſbandry, but to be the foundation of it, and the moſt eſſential and indiſpenſable part of good management. And it is likewiſe added, that "a farmer may be in poſſeſſion of the moſt valuable breed of cows, and theſe be fed in the richeſt paſtures; but unleſs cleanlineſs prevail in the dairy, his butter or his cheeſe will never ſtand high in general eſtimation." See DAIRY, and DAIRY-*Houſe*.

Next to the ſize and ſituation of the dairy-houſe, and to keeping it and the utenſils clean, is that of ſkill and attention in the general management. In ſhort, without a knowledge of the beſt modes proper to be adopted under different circumſtances, and a regularity, method, and prompt attention to their execution, it is obvious that the buſineſs muſt ſoon run into confuſion, and become unprofitable.

In reſpect to the neceſſary expence of the proper apparatus for this purpoſe, ſuch as churns, milk-pails, cheeſe-cloths, trays or pans, braſs milk-kettle, and boiling copper, &c. excluſive of the cheeſe-preſs, for a dairy of twenty cows, it will moſtly be about fifty pounds. For fuel either coal or wood will anſwer, but faggots preſerved in the ſtack one year are much the beſt material that can be employed.

Sorts of Cows proper for dairying.—It is ſuggeſted that, on the richer and more fertile paſtures, it is probable that the large and middle-ſized breeds of cows may be the moſt beneficial, eſpecially where both cheeſe and butter are made; but in ſuch as do not poſſeſs ſuch a high degree of fertility, the middle and ſmaller breeds may prove more profitable to the dairy-farmer. Some ſuppoſe the long-horned breed not well ſuited for the dairy; but experiments that have been carefully made ſhew that more cheeſe may be produced from the ſame quantity of milk in that breed than in thoſe of the ſhort-horned, as well as more butter from the ſame quantity of cream. And in Ireland, the Craven breed afford more butter than the Holderneſſe. Of the ſmaller breeds, the Alderney, the Suffolk-polled, and the Kiloe or Scotch breeds, may be found the moſt profitable. In the dairies of the Iſle of Wight, as well as thoſe of ſome parts of Hampſhire, the Alderneys prevail much, and are highly eſteemed for butter. Two-thirds of the Suffolk-polled breed, and one-third Alderney, have been recommended as conſtituting an excellent dairy-ſtock, the milk

milk being mixed. And it is added, that, beſides the milk, there is another object to be attended to in forming a cow-ſtock, which is, that they be ſufficiently hardy for the ſituation. In this reſpect the long-horned breed is much ſuperior to the ſhort-horned cattle, from the difference in the thickneſs of their hides; and the Scotch is probably better than either. This breed and the long-horned are therefore the moſt proper for bleak expoſed ſituations. And as many of the mixed-breeds afford excellent milkers, and in moſt of the genuine breeds there are great differences in the individuals, it may be the beſt mode, in order to eſtabliſh a good dairy-ſtock, whether for butter or cheeſe, for the farmer to breed from ſuch cows, of whatever kind they may be, as he has found from experience the beſt for the purpoſe, without being at the trouble of purchaſing the more expenſive breeds. In this caſe good bulls ſhould always be procured, as much is ſuppoſed to depend on the male.

In the vale diſtrict of the Glouceſterſhire dairy-farmers, it is remarked by Mr. Rudge, that thoſe neat cattle are in general kept which have the beſt bags, and which are the moſt likely to afford the largeſt ſupply of milk; the beauty of the animal being of courſe an inferior conſideration, though not wholly overlooked, or neglected; as it is well known, that when the cows are turned off to fatten, thoſe will improve in the moſt ſpeedy manner which have the beſt forms, and conſequently the feweſt coarſe points about them. Although ſeveral varieties have been introduced, in ſome of the old dairies, the Glouceſterſhire breed is ſtill much valued; yet few ſtocks are met with in the county in which there is not ſome mixture, and perhaps ſtill fewer in which the "genuine old ſtock is preſerved." It is added, that this breed differs but little in its general appearances from that of the Glamorganſhire, except in colour, which is a dark red or brown: the bones are fine, the horns of a middling length, white in colour, having a black tip at the ends, the bag by no means fleſhy, but large, affording a great deal of milk, and continuing it for a long time, when on good keep. They have generally a ſlight ſtreak of white running along the back, and conſtantly on the rump end of the tail. They are light in the carcaſe, commonly weighing from eight to nine ſcore the quarter. Their milk is ſaid to be leſs rich in quality than in ſome other breeds.

In the higher vale diſtrict of the ſame county, the improved long-horned ſort from the ſtock of Bakewell and Fowler are in the moſt eſtimation. And on the Cotſwolds, the principal occupiers encourage the ſame kind. Thoſe of the Devonſhire ſort are likewiſe admired by ſome for this uſe in theſe ſituations, being tolerable milkers, good breeders, little conſumers, and excellent feeders. The merits of this breed, as milkers, have probably not been ſufficiently attended to and aſcertained by proper trials; as it has been found, by a perſon in the vicinity of Devizes, Wiltſhire, who, as well as his father before him, has been in the habit of letting cows to men who ſupply that town with milk; and who buys all his cows, and conſequently, can have no partiality for any particular ſort, having, at different times, had all kinds; that the milk-men have uniformly, for the laſt thirty years, given the preference to the Devonſhire ſort at the ſame price, as being, on the whole, the beſt milkers. The Suffolk duns are found in ſome inſtances, in this diſtrict, milking indifferently well, and having much propenſity to fatten.

But a croſs of the Glouceſterſhire breed with that of the long-horned is found, on the experience of an extenſive cow-keeper, who raiſes his own ſtock, to anſwer his purpoſe in the moſt perfect manner; ſome of this ſort of cows affording from two to three gallons or more of milk at each time of milking.

In Cheſhire the cows of the dairy-farmers are compoſed of almoſt all the different ſorts or breeds: and, according to Mr. Holland, ſome perſons prefer "half-bred cattle from the Lancaſhire and preſent Cheſhire; others prefer a breed between the Cheſhire and Lancaſhire; and there are thoſe who prefer a half breed between the Cheſhire and the Welſh; whilſt a croſs between the Lancaſhire and Holderneſſe, and one between the Lancaſhire and Welſh, have alſo their advocates."

It is ſtated, that on the better ſorts of land, "a breed partaking of the ſhort-horned Holderneſſe, or the long-horned Lancaſhire, ſeems to be the moſt prevalent." While, on the inferior ſorts of land, "a middle-ſized ſhort-legged breed, with a croſs of the Welſh in them, are the moſt preferred." In ſhort, the "ſize, form, and production of the udder," is there more attended to than "the figure and bulk of the beaſt." The improved breeds do not appear to have anſwered. The cows that are bred *upon the land* are found, it is ſaid, to anſwer beſt. The cows kept for the purpoſe of the Cheſhire dairies, it is ſuppoſed, will not, on the average, weigh more than ſeven ſcores the quarter, when fattened. It is found and admitted in this diſtrict, that this ſort of ſtock is often kept too long without changing. Where cows are found to be good milkers, they are, indeed, too frequently kept for that uſe, until of little value for any other. "An old cow may give more milk than a young one, but it is not of ſo rich a quality; but this is not the whole, "for an old beaſt will require more and better food to keep her in a condition, and in full milk, than one of a proper age; which is thought to be between four and ten years; but there are many who think that a milker is not in her prime till five years old." See Cow.

In the rearing of young cow-ſtock in this diſtrict, the calves are ſelected from the beſt milkers, a cuſtom which applies to the males as well as the females. Thoſe are chiefly fixed upon which are calved early, as in February, or early in the following month; being, for the firſt three weeks, moſtly kept on the cows; but afterwards ſerved with warm green whey, ſcalded whey and butter milk mixed, or hard fleetings; of which latter ſorts of food, about five quarts conſtitute a meal for each calf: but with the firſt kind or green whey, water is often mixed, with oat-meal, wheat, or bean-flour, in the proportion of about a quart to forty or fifty quarts of the liquid, which is ſufficient for a meal for ten calves. And where flax ſeed is had recourſe to, a quart of the boiled ſeed is given, in addition to the whey, for the ſame number of calves. A gruel made with oat-meal and butter-milk, in mixture with a little ſkimmed milk, is likewiſe ſometimes uſed for the ſame purpoſe. One or other of theſe kinds of food being at firſt ſerved night and morning, but in the latter part of the time only once in the day; as, till the calves are turned out to graſs, and for ſome time afterwards, being, on the whole, continued for about ten weeks. A good paſture is reſerved for the calves in the firſt winter, a little hay being given them night and morning, as ſoon as hard weather takes place. In the ſecond winter they have the dry food of ſtraw, having an open ſhed near the paſture for an occaſional ſhelter, but which is better in the farm-yard. The ſummer following, the heifers, which are two years old offs, are put to the bull. In the third winter, in ſome caſes, they lie out in the fields till near calving time; but in others, which is much better, they are tied up at the ſame time with the milking cows; being, in each caſe, fed with ſtraw, night and morning, till about a month before calving. See Calf-*Rearing*.

Proper kinds of Food for the Cows.

In order to make cows give abundance of milk, and of a good quality, they muſt at all times have plenty of food. Graſs is the beſt food yet known for this purpoſe; and that kind of graſs which ſprings up ſpontaneouſly on rich dry ſoils is the beſt of all. But ſo little attention has hitherto been beſtowed on this ſubject, Dr. Anderſon ſays, that he does not know of any ſet of experiments that have ever yet been made, with a view to aſcertain the effects of any of the natural graſſes that ſpontaneouſly ſpring up in abundance on our fields, either on the quantity or the quality of the milk of cows, and few that have been attempted even with regard to thoſe plants that have been cultivated by art as green forage for them; though it be well known, that ſome particular kinds of plants ſtrongly affect the taſte and alter the quality of particular products of milk. It is, indeed, in all caſes, confidently aſſerted, that old paſtures alone can be made to afford rich butter or cheeſe. This, however, he knows from his own repeated experience to be a popular error, as he has frequently ſeen much richer butter made by one perſon from cows that were fed in the houſe chiefly with cut clover and rye-graſs, than that which was made by others where the cows were fed on very rich old paſtures. Mankind, ſays he, are in general diſpoſed to throw the blame of every failure upon ſome circumſtance that does not reflect on themſelves as bad managers. Hence it is, that the graſs of a farm is often blamed for the want of richneſs of the butter produced upon it; when, if the circumſtances were fully inveſtigated, it would be found to be occaſioned by the unſkilfulneſs of the dairy-maid, or the want of attention in the choice of proper cows.

If, in the management of the cows in the ſummer ſeaſon, the temperature of the climate be ſuch as to permit them to graze at eaſe throughout the day, they ſhould be ſuffered to range on ſuch paſtures at freedom; but, if the cows are ſo much incommoded by the heat, as to be prevented from eating through the day, they ought, in that caſe, to be taken into cool ſheds for protection; where, after allowing them a proper time to ruminate, they ſhould be ſupplied with abundance of green food freſh cut for the purpoſe, and given to them by hand frequently, in ſmall quantities, freſh and freſh, ſo as to induce them to eat it with pleaſure. In very warm climates, where the heat is extremely oppreſſive to cows, and the flies are exceedingly troubleſome, ſheds open on one ſide, the roof being only ſupported there by pillars, would not, the writer thinks, afford them ſuch effectual ſhelter as they would require. In theſe caſes, the ſheds ſhould be walled upon both ſides, and be left open only at the two ends, which, if properly placed, would produce a continued ſtream of air throughout the whole building that would prove highly ſalutary to the cattle. When the heat of the day is over, and they can remain abroad with eaſe, they may be again turned into the paſture, where they ſhould be allowed to range with freedom all night during the mild weather of ſummer. See DAIRY.

It is adviſed by Mr. Rudge, in his account of the management of the cows in Glouceſterſhire, that the dairy farmer ſhould mark out thoſe incloſures for cow-paſtures, which are known either from a previous examination of the herbage, or from the experience of others, to be the moſt ſuited to the purpoſe of producing good milk, without its being of a rank quality.

In the winter keeping of the cows, there are different methods in uſe in different diſtricts; but in the ſouthern parts of the iſland they do extremely well in warm ſheltered yards, with open ſheds, eſpecially when plenty of litter, ſuch as ſtraw, ſtubble, fern, or other ſimilar materials, can be afforded for keeping the whole well bedded. In the northern diſtricts, however, and wherever a proper ſupply of litter cannot be obtained, it is better to have them tied up in ſtalls, with raiſed ſtandings, and ſunk paved floors immediately behind them, for receiving the dung and urine, as by theſe contrivances they may be kept perfectly clean without litter, and at the ſame time be more warm, as two cows may be confined in the ſame ſtall. The ſtalls ſhould be kept conſtantly clean and well ſweeped out.

It has been obſerved to be of great conſequence to the produce of a dairy, that the cows ſhould not drop their calves too early in the ſeaſon. When that happens, they fall off in the quantity of milk in the autumn, when, owing to its ſuperior richneſs, it is more valuable than at any other period. From the end of March to the end of April is the beſt time, in the more northern diſtricts, that a cow can drop her calf, as ſhe ſoon gets into good condition on the early graſs, and yields a greater quantity of milk in the courſe of the ſeaſon than thoſe that calve either conſiderably earlier or later. But in the ſouthern parts of the iſland it is an advantage for them to calve much earlier. In Cheſhire, the above period is the uſual time, only a few cows dropping their calves in January or the following month.

With regard to the management of cows in ſummer, there is a ſimilarity in almoſt every diſtrict. They are uſually kept on the oldeſt paſtures on the farm: when theſe are at a diſtance from the farm-houſe, they are milked on the paſtures; but otherwiſe they are brought home morning and evening for that purpoſe.

But in winter the dry cows, that is, ſuch as do not give milk, are fed on ſtraw in the ſtraw-yard; while thoſe that are in milk, or are near calving, are kept in ſome incloſed paſture, or in ſheds erected for the purpoſe, and maintained chiefly on hay. Where artificial graſſes, turnips, cabbages, or potatoes, are cultivated on a large ſcale, the milch cows have a daily and regular allowance of one or other of theſe ſorts of food during the winter and ſpring months. Potatoes, in particular, are admirable food for cows; as, while they tend to keep them in good condition, the quantity of milk is generally abundant and of good quality, both in reſpect to richneſs and flavour. In ſhort, the dairy-farmer, in every part of the iſland, will find it for his intereſt to be attentive in feeding his cows, whatever the ſort of food may be which he employs. It may be ſtated that of theſe different ſorts of food, the diſtribution for ſummer and winter may be in the following manner:

For the ſummer, red clover, ſainfoin, lucern, burnet, and tares, may be made uſe of with great advantage. But in employing the firſt, great care ſhould be taken to guard againſt injury either to the animals, or the quality of the butter or cheeſe being rendered of a bad kind or flavour by it. On poor chalky hills, the ſecond will be of the greateſt importance to the dairy-farmer. Lucern and tares ſhould always be employed in the way of ſoiling; in which method, where the cows have proper ſhade and ſufficient water, they will be found of the utmoſt uſe, as they afford a very certain ſupply of food and go a great way. Beſides, the cows are found to milk well in this management, where proper attention is beſtowed in the foddering of them. It is ſuppoſed a method that can hardly be too ſtrongly adviſed, by a writer in the thirty-ſecond volume of the Annals of Agriculture. In Mr. Baker's experiments, a middle-ſized cow was found to conſume in the proportion of from ninety to one hundred pounds of green lucern in the courſe of twenty-four hours.

But for winter, hay, ſtraw, cabbages, turnips, carrots, potatoes, cole, malt-grains, &c. ſhould be had recourſe to. The keeping of cows with hay is in general too expenſive to

afford the dairy-man an adequate profit: therefore, in order to leſſen the expence of this ſort of keep, other articles of the green and root kind muſt be had recourſe to; till near the period of calving they may be ſupported on freſh threſhed ſtraw in cribs in the fold-yard, beginning with the worſt, and gradually proceeding to that which is of a better quality. Thoſe in good condition ſhould have the worſt ſtraw; but when it is not of the beſt kind, and the cows are of a valuable ſort, they may be fed once a day with cabbages, turnips, or other ſimilar ſorts of food, in bins for the purpoſe. When within about a month or ſix weeks of calving, a little hay ſhould be given at night, or the allowance of green food increaſed, and on the day of calving they ſhould be confined and have warm water, and for a fortnight after calving be very well fed with both hay and green food, in ſuitable diviſions for the purpoſe. In this view the cabbages are extremely valuable, as the produce on the acre is large, and they afford much milk; but care muſt be taken to pick off all the dead and decayed leaves, which may be given to the young ſtock. A middle-ſized cow will conſume from one to two hundred pounds in a day; but ſeventy is ſuppoſed as much with ſtraw as can be paid for by the produce. In Mr. Dodſworth's trials, as aſſerted by Mr. Young in his ſix months' Tour, a cow of fifty ſtone was found to eat twelve ſtone of this ſort of food in the ſame time. An extent of this kind of crop, proportioned to the dairy, ſhould always be provided. The only objection to turnips as food for milch cows, is their impairing the flavour of the butter; but they are a ſort of food that affords much milk, and without this, or the preceding green food, a large dairy cannot, perhaps, be ſupported to much profit. A larger weight of this food than the former is conſumed in the ſame time.

In reſpect to carrots and potatoes, they are very advantageous ſorts of food for cows, where they are raiſed in great abundance; but even in ſuch caſes they can only be made uſe of with profit as a feed once or twice in a day with other ſorts of food. It is out of the queſtion that a cow could pay for being kept wholly on them. Cole, as being fed off in the field, can only be had recourſe to on the firm dry ſoils; but in ſuch ſituations it is a very profitable crop applied in this way, eſpecially when uſed in ſucceſſion to turnips in the ſpring months. Malt-grains, where they can be had in plenty, are uſeful with other ſorts of food, as producing a large proportion of thin milk. They are conſe-ſequently better for the purpoſes of the milkman than the dairy-farmer.

In the Cheſhire practice of dairying, the uſual dry foods are, according to Mr. Holland, wheat, barley, and oat-ſtraw, hay, and cruſhed oats; the two former kinds of ſtraw are, however, found to make cows go dry much ſooner than the latter: and there is, likewiſe, another effect, which is generally admitted, as depending upon this ſort of keep, which is, that the cream of the cows, which have been thus fed, will require more than the uſual time in churning. Wheat-ſtraw, notwithſtanding, is conſidered much more wholeſome than that of barley, as having leſs of ſuch effects attending it.

Thoſe cows which, at the period of houſing, are not expected to calve until rather late in the ſpring, are fed with oat-ſtraw, and ſometimes hay, while they are milked; having wheat, or barley-ſtraw, afterwards given them. On the contrary, the more forward in calf cows, on being taken up, are put either to wheat or barley-ſtraw, according as circumſtances may ſuit; oat-ſtraw not being given them until the whole of the other ſtraw is conſumed. This, however, depends much on the price of the markets for grain. In either caſe, the ſtraw fodder is continued until about three or four weeks before the time the cows are expected to calve; when they have hay in the proportion of from two to two and a half hundred weights per week each cow. And from the time the cows have calved, until they are turned out to graſs, a portion of ground, or cruſhed oats, is given them twice a day; in general, from twenty to twenty-five quarts per week, to each cow. And chopped ſtraw has frequently been made uſe of in years when hay has been ſcarce, by many farmers, a little corn being mixed with it; two ſmall fodderings of hay being only given in the day, and occaſionally a foddering of ſtraw at night.

In the management of the cows, they are turned out into an *out-let*, (a bare paſture field contiguous to the buildings,) about ten o'clock in the morning, and houſed again about four in the afternoon, throughout the whole winter, in which they have, however, no fodder. It is, indeed, ſuggeſted, as the practice of many dairy-farmers, after the cows have been turned into the out-let or paſture, and begin to manifeſt a diſpoſition to be taken up again, to let them into the yards and be houſed, which, in cold or wet weather, is conſidered a much better practice than that of ſuffering them, as is uſually done, to ſtand ſhivering with cold in the field without ſhelter or protection.

It is ſtated as a matter of much conſequence, to turn the cows out to graſs in good condition, in order, as the term is, that they may "ſtart well;" as where a cow is not in good condition, when turned out to graſs, or has been too much dryed with barley-ſtraw, it is a long time before ſhe gets into full milk.

It is ſtated by John C. Curwen, eſq. in the fifth volume of Communications to the Board of Agriculture, that much advantage has been found in his winter milk-dairy, from the practice of combining ſteamed chaff and ground oil-cake with different ſorts of green food. He has found, from actual experiment, that, when ground and boiled with chaff, the cake is more productive of, and increaſes the quantity of the milk much more than when given in the ordinary manner. And, beſides, there is a conſiderable reduction in the daily expence of the keep. In this way, the keep of a middling-ſized cow is ſtated to be only five-pence halfpenny *per* day, thus:

	ſtones.	*lbs.*	*d.*
Green food - -	2	0 -	$0\frac{1}{2}$
Boiled chaff - -	2	0 -	2
Oil cake ground -	0	2 -	2
Straw from ſix to -	0	8 -	1
Total weight -	4	10 -	$5\frac{1}{2}$

This is a method of feeding cows in the ſtate of milking, which, from its convenience and beneficial effects, is much deſerving of the dairy and cow-farmer's notice. We have ſtated it more in detail in ſpeaking of the buſineſs of the milk-dealer. See Cow-*Keeping*.

In reſpect to the practice of giving green food, or what is termed ſtall-feeding, cows, it is remarked by Mr. Holland, in his Survey of Cheſhire, that the more general uſe of this ſort of food, and that of conſuming it in the ſtalls or yards, are unqueſtionably to be conſidered as the greateſt improvements which have lately taken place in the rural management of that diſtrict. It is a principal object, he ſays, with the dairy-farmer, to increaſe the quantity of his milk, and continue it as long as poſſible; which can be no way more effectually accompliſhed, than by the giving of green food to his cattle. The writer is, indeed, aſſured, by different ſenſible farmers, that by this means the milk may be

continued

continued a month longer in the autumn than could be done by truſting ſolely to the paſtures for the ſupply of food, which is a circumſtance, the importance of which is ſufficiently evident.

The ſorts of green food which are moſt in uſe in this diſtrict are the ox-cabbage, and the Swediſh turnip; the former being moſtly given to the cows, when the after-graſs has been conſumed; though ſometimes in the ſpring, to ſuch cows as have newly calved. And when the paſtures begin to fail, and the after-graſs is not ready, which often happens, eſpecially in dry ſeaſons, they have recourſe to the large ſugar-loaf cabbage. The latter ſort of food or turnips are given to the cattle, while feeding on ſtraw in the winter ſeaſon, and to which, as at this period no cheeſe is made, there can be no objection to their uſe, in the ſuppoſition of their injuring the flavour of the milk.

It is ſtated by the ſame intelligent writer, that, on inquiry, whether the practice of ſtall-feeding the milch cows might not be continued the whole year round, he has found the general opinion of farmers in the diſtrict to be againſt it; though it does not appear, he ſays, that this is founded upon any deciſive trials which have been made with a view to aſcertain the point. It has, however, been ſuggeſted to him as an improvement on the preſent management, to let the cows ſtand in their houſes during the heat of the day, in the ſummer ſeaſon; in which caſe, by giving them a few cabbages or tares, the milk would continue forming, and the cattle be defended from the gad-fly, which, by tormenting them in the fields, frequently injures the milk both in quantity and quality.

In the practice of Mr. Curwen, above alluded to, various other articles of green food were had recourſe to with advantage; ſuch as kohlrabi, red turnip, and cole, the laſt of which was found excellent in promoting a flow of milk, as well as for continuing as a food.

But, whatever kinds of green or ſucculent food may be uſed in the way of feeding dairy-cows, it is remarked, by a late writer, that experience has ſhewn that great advantage may be derived from varying it as much as poſſible, probably on the phyſiological principle, that the novelty of ſtimulus is the moſt powerful in exciting the action and promoting the ſecretions of the ſyſtem. The uſe of day and night paſtures, which is a method employed in ſome diſtricts, may alſo partly depend, it is ſuppoſed, on this principle, and partly on that of better ſhade and water. This mode, according to Mr. Wedge, is in uſe on the Cheſhire dairy-farms.

In Cheſhire, and moſt of the other dairying diſtricts, the cows are uſually taken up into the cow-houſes, ſheds, yards, or other places, towards the middle of November, or as ſoon as the weather begins to ſet in unfavourably. And, as it is ſuppoſed, that when the cows are kept to their milk too long, they are rendered leſs profitable in the following ſeaſon; it is common there to permit them to become dry about ten weeks before the time of their calving. Where they are well fed, this is, however, wholly unneceſſary. See Cow.

It may be remarked, that, in the ſtocking of paſture-lands with cows, it ſhould always be done according to their goodneſs; ſuch graſs-lands as afford, in rent, tythe, and taxes, twenty-ſeven or twenty-eight ſhillings, may ſupport, during the ſummer ſeaſon, in the proportion of a cow of fifty ſtones to an acre and a half, with a few ſheep. But in ſuch as are not worth more than twenty ſhillings, one cow to two acres may be often fully ſufficient. But in this management the rule ſhould be for the paſtures never to be too cloſely ſtocked, or have too many upon them at a time. The intelligent author of the corrected Cheſhire Report on Agriculture, ſtates, that the quantity of land which is ſufficient to keep one cow the whole year, muſt, of courſe, vary with the quality and produce of different ſoils, and the ſize and nature of the beaſt; but that, probably, on the average, having regard to the quantity of hay and corn conſumed, as well as to the graſs and ſtraw, a cow, in the courſe of the year, will conſume the produce of three ſtatute acres of land.

In the care and management of a large dairy of cows, or, what, in moſt of the dairy diſtricts, is termed a *pack* of cows, there is almoſt a conſtant and unabated attention required. In Cheſhire, it is the common rule, at the period of the cows calving, for the cow-man, or maſter of the dairy himſelf, to get up two or three times during the night, to ſee that every thing is right. The racks, cribs, or mangers, are kept conſtantly well cleaned; and great regard paid to the appetites of the different beaſts, in order that the quantity of food may be ſuitably apportioned. And after this, it is not unfrequently a practice with the maſter to go round himſelf, from ſtall to ſtall, immediately before he goes to bed, in order that he may add to or diminiſh the quantity of fodder in the manner that may be neceſſary.

The labour which is neceſſary in the management of dairy buſineſs, muſt evidently differ materally, according to convenience, and various other points of inferior conſideration; but it is ſeldom poſſible for an ordinary dairy-maid to manage a greater number of cows than fourteen or fifteen in any very perfect manner, particularly where the practice of making both butter and cheeſe is had recourſe to. Where a greater number are undertaken, aſſiſtance will be required in the dairy. And, as it is eſſential that the cows ſhould not be kept longer in being milked than an hour, in which time one maid cannot milk more than five or ſix cows, it is evident, that where ſixteen or eighteen cows are kept in the ſtate of milking, it will be neceſſary to have the aſſiſtance of two others at ſuch periods; in which proportion the work of the dairy may be conſtantly regulated.

Milking the Cows.

It has been ſtated, as a general practice, that cows are only milked twice a day; but that, when "abundantly fed, they ſhould, probably, be milked three times a day during the whole of the ſummer ſeaſon: in the morning early, at noon, and in the evening, juſt before night-fall. For, if they be milked only twice in the twenty-four hours, while they have abundance of ſucculent food, they will yield a much ſmaller quantity of milk in the ſame time, than if they were milked three times." It has, indeed, been obſerved, by ſome attentive inquirers, that a cow, in theſe circumſtances, will give nearly as much milk at each time of milking, if milked three times, as if ſhe were milked only twice. This is, however, a ſtatement which has not probably been aſcertained by the teſt of experiment. But it is ſuppoſed, there is no doubt of their giving more, though how much more has not been fully decided. Nor has it been aſcertained whether it would be advantageous, in any caſe, to have the cows milked four times, or oftener; or what effect frequent milking produces on the quality of the milk. In ſpeaking of the practice of procuring milk for the purpoſe of ſale in large towns, ſome experiments were ſtated on this ſubject. See Cow-*Keeping*.

In the choice of perſons for milking the cows, great caution ſhould likewiſe be employed: for, if that operation be not carefully and properly performed, not only the quantity of the produce of the dairy will be greatly diminiſhed, but its quality alſo very highly debaſed; for, if all the milk be not thoroughly drawn from a cow when ſhe is

milked, that portion of milk which is left in the udder ſeems to be gradually abſorbed into the ſyſtem, and nature generates no more than to ſupply the waſte of what has been taken away. If this leſſened quantity be not again thoroughly drawn off, it occaſions a yet farther diminution of the quantity of milk generated; and ſo on it may be made to proceed in perpetual progreſſion from little to leſs, till none at all is produced. In ſhort, this is the practice in all caſes followed, when it is meant to allow a cow's milk to dry up entirely, without doing her hurt. In this manner, therefore, the profits of a dairy might be wonderfully diminiſhed; ſo that it behoves the owner to be extremely attentive to this circumſtance if he wiſhes to avoid ruin. It ought to be a rule without an exception, never to allow this important department to be entruſted, without controul, to the management of hired ſervants; as cows ſhould always be treated with great gentleneſs, and ſoothed by mild uſage, eſpecially when young and tickliſh, or when the paps (teats) are tender: in which laſt caſe the udder ought to be fomented with warm water before milking, and touched with the greateſt gentleneſs, otherwiſe the cow will be in danger of contracting bad habits, becoming ſtubborn and unruly, and retaining her milk ever after. A cow never lets down her milk pleaſantly to the perſon ſhe dreads or diſlikes. The udder and paps ſhould always be waſhed with clean water before milking; but care ſhould be taken that none of that water be admitted into the milking-pail. The importance of this is ſtill more manifeſt from many circumſtances which take place in reſpect to milk; and many of which, in ſo far as they reſpect the dairy, have been but little, if at all, noticed, though they have evidently much effect on the different proceſſes and products reſulting from them. See MILK and COW-*Keeping*.

In caſes where two milkings are only practiſed in the courſe of the day, they ſhould be performed about five o'clock in the morning, and about ſix at night. And it is a practice which the dairy-maid or man ſhould conſtantly attend to with exactneſs, to examine the cows carefully after the milkers, where they cannot be fully depended upon, in order to aſcertain that the operation has been effectually performed; as, under the contrary circumſtances, loſs may not only be incurred in the richeſt part of the milk, but the cows rendered dry before the proper period, and at the ſame time made more liable to diſeaſes of the udder.

The average quantity of milk which is afforded by cows is very different in different circumſtances, depending materially on paſtures, ſeaſon, and the mode of winter keeping; but in the principal cheeſe diſtricts, from eight to twelve quarts per day is the uſual proportion; though many cows will give twice theſe quantities for ſhort periods; but when cows give more than the firſt of theſe quantities at a meal, it is remarked that they "either go off their milk much ſooner, or elſe their milk has leſs richneſs in it, than that of others which do not give ſo large a quantity."

Managing of the Milk, for Butter.

In reſpect to the managment of the milk, it may be obſerved to be a circumſtance of the utmoſt importance to the ſucceſs of the dairy-buſineſs, as upon its being properly executed, the profit of the farmer muſt in a great meaſure depend.

It is the commor practice in moſt of the dairy-diſtricts of the kingdom to paſs the milk, as ſoon as it has been brought from the cows, through ſome ſort of ſtrainer, which is uſually a hair or fine wire ſieve, firmly ſecured in the bottom of a large bowl formed of wood; or where the dairy is extenſive, a ſort of trough fixed conveniently for the purpoſe, ſo as to diſcharge the milk into the trays or other veſſels deſtined for the purpoſe of receiving it. See DAIRY-*Houſe*.

The trials which have hitherto been attempted, in order to aſcertain or determine the moſt beneficial manner of diſpoſing the milk, with the view of producing and throwing up the cream in the greateſt abundance, and the ſhorteſt ſpace of time, have been but few, and thoſe made without much accuracy or correctneſs. But as the oily portion of the milk which conſtitutes the butter ſeems to be diffuſed throughout the whole ſubſtance of the milk, and to be entangled among the ſerous and caſeous particles of it, in ſuch a manner as to be thrown up to the ſurface only in conſequence of its having a leſs ſpecific gravity than the part which is commonly denominated milk, while in the ſtate of reſt; it would appear that the method of placing it, which is moſt adapted to the proper, full, and expeditious creaming, is that of depoſiting it in very ſhallow baſons, pans, trays, or leads, ſo as not to ſtand at a greater depth than about three inches; as under ſuch circumſtances, there will be the leaſt reſiſtance afforded to its riſing, and at the ſame time the greateſt poſſible extent of ſurface for it to collect upon. And experience has ſhewn, in ſome of the beſt butter dairy-diſtricts, that, in this way, a large proportion of cream is afforded, and at the ſame time, in conſequence of the more expeditious manner in which the milk cools, the tendency of it to run into the ſtate of acidity, in warm ſeaſons, is much checked and reſtrained.

It has not been ſhewn, as the reſult of experiments, what kind of ſubſtance is the moſt proper and advantageous in this intention, for the forming of ſuch veſſels of; though there can be little doubt, but that wood, ſtone, or ſlate, are any of them preferable to lead, not only from their being capable of being kept clean with much greater facility, and being leſs apt to fur, but from their being more ſafe, in conſequence of their not being liable to be acted upon by the acid of the milk.

The following obſervations have been made by doctor Anderſon with reſpect to milk: firſt, that, of the milk that is drawn from any cow at one time, that which comes off at the firſt is always thinner, and of a much worſe quality, than that which comes afterwards; and the richneſs goes on, continually increaſing, to the very laſt drop that can be drawn from the udder at that time. Few perſons, ſays he, are ignorant, that milk which is taken from the cow laſt of all at milking, which is often provincially called ſtroakings, is richer than the reſt of the milk; but very few are aware of the greatneſs of the diſproportion between the quality of the firſt and the laſt drawn milk from the ſame cow at one milking. The following facts reſpecting this circumſtance were, he ſays, aſcertained by him many years ago, and have been confirmed by many ſubſequent experiments and obſervations. Having taken ſeveral large tea-cups exactly of the ſame ſize and ſhape, one of theſe tea-cups was filled at the beginning of the cow's milking, and the others at regular intervals till the laſt, which was filled with the dregs of the ſtroakings. Theſe were each weighed, the weight of each cup being ſettled ſo as to aſcertain that the quantity of milk in each was preciſely the ſame; and from a great number of experiments, frequently repeated with many different cows, the reſult was in all caſes thus:—the quantity of cream obtained from the firſt drawn cup was, in every caſe, much ſmaller than from that which was laſt drawn; and thoſe between afforded leſs or more as they were nearer the beginning or the end. It is unneceſſary here to ſpecify, he ſays, theſe intermediate proportions; but it is proper the reader ſhould be informed, that the quantity of cream obtained from the laſt drawn cup, from ſome cows, exceeded that from the firſt

In the proportion of ſixteen to one; in other cows, however, and in particular circumſtances, the diſproportion was not quite ſo great, but in no caſe did he find it fall ſhort of the rate of eight to one. Probably, upon an average of a great many cows, it might be found to run as ten or twelve to one. And that in the next place, the difference in the quality of the cream, however, obtained from theſe two cups, was much greater than the difference in the quantity. In the firſt cup the cream was a thin tough film, thinner, and perhaps whiter, than the paper on which he writes: in the laſt, the cream was of a thick butyraceous conſiſtence, and of a glowing richneſs of colour, that no other kind of cream is ever found to poſſeſs. And laſtly, that the difference in the quality of the milk, that remained after the cream was ſeparated, was, perhaps, ſtill greater than either, in reſpect of the quantity or the quality of the cream. The milk in the firſt cup was a thin blueiſh liquid, like as if a very large proportion of water has been mixed with ordinary milk; that in the laſt cup was of a thick conſiſtence and yellow colour, more reſembling cream than milk, both in taſte and appearance. From this important experiment it appears, he ſays, that the perſon who, by bad milking of his cows, loſes but half a pint of his milk, loſes in fact about as much cream as would be afforded by ſix or eight pints at the beginning; and loſes, beſides, that part of the cream which alone can give richneſs and high flavour to his butter, when that is the object of the dairy-man. Many other uſeful corollaries may, he ſays, be drawn from it, ſome of which will occur in the ſequel.

In the ſecond place, he ſays, that if milk be put up in a diſh, and allowed to ſtand till it throws up cream, that portion of cream which riſes firſt to the ſurface is richer in quality, and greater in quantity, than what riſes in a ſecond equal portion of time; and the cream that riſes in the ſecond interval of time is greater in quantity, and richer in quality, than that which riſes in a third equal ſpace of time; and that of the third than the fourth, and ſo on: the cream that riſes decreaſes in quantity and declines in quality continually, as long as any riſes to the ſurface. Theſe experiments not having been, in this caſe, made with ſo much accuracy as in the former, he has not been able to aſcertain the difference in the proportion that takes place in equal portions of time; but they have been ſo often repeated as not to leave any room to doubt the fact; and it will be allowed to be a fact of no ſmall importance in the management of the dairy. It is not certain, however, but that a greater quantity of cream may upon the whole be obtained from the milk, by taking it away at different times; but the proceſs is ſo troubleſome, as not to be counterbalanced by the increaſed quantity obtained: if, indeed, an additional quantity be thus obtained, which is not as yet, he thinks, fully certain.

In the third place, it is added, that thick milk always throws up a ſmaller proportion of the cream it actually contains to the ſurface than milk that is thinner; but that cream is of a richer quality; and if water be added to that thick milk, it will afford a conſiderable greater quantity of cream than it would have done if allowed to remain pure; but its quality is at the ſame time greatly debaſed. This is, he believes, a fact that every perſon attentive to a dairy muſt have remarked; but he has never heard of any experiment that could aſcertain either the preciſe amount of the increaſed quantity of cream that might thus be obtained, or of the ratio in the decreaſe of its quality: but it aſcertains the effects, at leaſt, of mixing water with milk in a dairy; and the knowledge of this fact will enable attentive perſons to follow that practice which they think will beſt promote their own intereſt.

In the fourth place, that milk which is put into a pail, bucket, or other proper veſſel, and carried in it to any diſtance, ſo as to be much agitated, and in part cooled, before it be put into the milk-pans to ſettle for cream, never throws up ſo much nor ſo rich cream, as if the ſame milk had been put into the milk-pans directly after it was milked. In this caſe, it is believed, he ſays, that the loſs of cream will be nearly in proportion to the time that has elapſed, and the agitation it has ſuſtained, after being drawn from the cow; but he is not yet in poſſeſſion of any experiments that ſufficiently aſcertain how much is to be aſcribed to the time and the agitation taken ſeparately. From the whole of the facts and circumſtances, the ingenious author thinks the following corollaries ſeem to be clearly deducible. 1ſt. That it is of importance that the cows ſhould be always milked as near the dairy as poſſible, to prevent the neceſſity of carrying and cooling the milk before it be put into the diſhes: and as cows are much hurt by far driving, it muſt be a great advantage in a dairy-farm to have the principal graſs-fields as near the dairy, or homeſtead, as poſſible. 2dly. That the practice of putting the milk of all the cows of a large dairy into one veſſel, as it is milked, there to remain till the whole milking be finiſhed, before any part of it is put into the milk-pans, ſeems to be highly injudicious, not only on account of the loſs that is ſuſtained by agitation and cooling, but alſo, more eſpecially, becauſe it prevents the owner of the dairy from diſtinguiſhing the good from the bad cow's milk, ſo as to ſeparate theſe from each other, where it is neceſſary. He may thus have the whole of his dairy-product greatly debaſed by the milk of one bad cow for years together, without being able to diſcover it; as the author once ſaw a cow that gave milk which could never be made to yield any butter at all, though it had the appearance of being very rich milk. The perſon who ſold that cow had had her ſeveral years, along with a good many others, without having ſo much as had any ſuſpicion of this peculiarity. It was only diſcovered when ſhe came into the poſſeſſion of a perſon who had but one cow. A better practice, therefore, would be, to have the milk drawn from each cow ſeparately, put into the creaming-pans as ſoon as it is milked, without being ever mixed with any other. Thus would the careful *dairy* or perſon that ſuperintends the dairy, be able on all occaſions to obſerve the particular quality of each individual cow's milk, as well as its quantity, and to know with preciſion which of his cows it was his intereſt to diſpoſe of, and which of them he ought to keep and breed from. 3dly. That if it be intended to make butter of a very fine quality, it will be adviſable in all caſes to keep the milk that is firſt drawn ſeparate from that which comes laſt; as it is obvious, that, if this be not done, the quality of the butter will be greatly debaſed, without much augmenting its quantity. It is alſo obvious, that the quality of the butter will be improved in proportion to the ſmallneſs of the proportion of the laſt-drawn milk that is retained, ſo that thoſe who wiſh to be ſingularly nice in this reſpect will do well to retain only a very ſmall proportion of the laſt-drawn milk.

The writer here further remarks, that to thoſe owners of dairies who have profit only in view, it muſt ever be a matter of trial and calculation, how far it is expedient for them to carry the improving of the quality of their butter, at the expence of diminiſhing its quantity. In different ſituations, prudence will point out different kinds of practice as moſt eligible; and all perſons muſt be left, after making accurate trials, to determine for themſelves. It is likewiſe a conſideration of no ſmall importance, to determine in what way the inferior milk that is thus to be ſet apart, where fine butter is wanted, can be employed with the greateſt profit. In the

the highlands of Scotland, he ſays, they have adopted, without thinking of the improvement of their butter, a very ſimple and economical practice in this reſpect. As the rearing of calves is there a principal object with the farmer, every cow is allowed to ſuckle her own calf with a portion of her milk, the remainder only being employed in the dairy. To give the calf its proportion regularly, it is ſeparated from the cow, and kept in an incloſure along with all the other calves belonging to the ſame farm. At regular times cows are driven to the door of the calves' incloſure, where the young ones fail not to meet them. Each calf is then ſeparately let out, and runs directly to its mother, where it ſucks till the dairy-maid judges it has had enough, when ſhe orders it to be driven away, having previouſly ſhackled the hinder legs of the mother, by a very ſimple contrivance, to oblige her to ſtand ſtill. Boys drive away the calf with ſwitches, and return it to the incloſure, while the dairy-maid milks off what was left by the calf. Thus they proceed till the whole of the cows are milked, and thus do they obtain a ſmall quantity of milk, it is true, but that milk of an exceeding rich quality; which, in the hands of ſuch of the inhabitants as know how to manage it, is manufactured into the richeſt marrowy butter that can be any where met with. This richneſs of the Highland butter is, he obſerves, univerſally aſcribed to the old graſs the cows feed upon in their remote glens; but it is in fact chiefly, he conceives, to be attributed to the practice here deſcribed, which has long prevailed in theſe regions; and perhaps in ſome meaſure to the nature of the beaſt. Whether a ſimilar practice could be economically adopted elſewhere, he does not take upon him to ſay; but doubtleſs other ſecondary uſes might be found for the milk of inferior quality; on ſome occaſions, it might be converted into butter of an inferior quality; on others, it might be ſold ſweet, where the ſituation of the farm is within reach of a market town; on other occaſions, it might be converted into cheeſes, which, by being made of ſweet milk, would be of a very fine quality, if carefully made; and ſtill other uſes might be deviſed for its application. One mode of managing milk, by means of which the inferior kinds of it might, on many occaſions, eſpecially within reach of towns, be diſpoſed of to great advantage, is however mentioned, which is this: Take common ſkimmed-milk when it has begun to turn ſour, put it into an upright ſtand churn, or a barrel with one of its ends out, or any other ſimilar convenient veſſel. Heat ſome water, and pour it into a tub that is large enough to contain with eaſe the veſſel in which the milk was put. Set the veſſel containing the milk into the hot water, and let it remain there for the ſpace of one night. In the morning it will be found that the milk hath ſeparated into two parts; a thick cream-like ſubſtance which occupies the upper part of the veſſel, and a thin ſerous watery part, that remains in the bottom; draw off the thin part (called wigg) by opening a ſtop-cock placed for the purpoſe cloſe above the bottom, and reſerve the cream for uſe. Not much leſs than the half of the milk is thus converted into a ſort of cream, which, when well made, ſeems to be as rich and fat as real cream itſelf, and is only diſtinguiſhable from that by its ſourneſs. It is eaten with ſugar in ſome places, and is eſteemed a great delicacy, and uſually ſells at double the price of freſh ſkimmed milk. It requires practice, however, to be able to make this nicely; the degree of the heat of the water, and many other circumſtances, greatly affecting the operation. Theſe things practice beſt diſcovers.

And 4thly, that if the quality of the butter be the chief object attended to, it will be neceſſary not only to ſeparate the firſt from the laſt drawn milk, but alſo to take nothing but the cream that is firſt ſeparated from the beſt milk, as it is this firſt riſing cream alone that is of the prime quality. The remainder of the milk, which will be ſtill ſweet, may be either employed for the purpoſe of making ſweet milk-cheeſes, or it may be allowed to ſtand, to throw up cream for making butter of an inferior quality, as circumſtances may direct.

5thly. That, from the above facts, we are enabled to perceive that butter, of the very beſt poſſible quality, can only be obtained from a dairy of conſiderable extent, when judiciouſly managed; for, when only a very ſmall portion of each cow's milk can be ſet apart for throwing up cream, and when only a very ſmall proportion of that cream can be reſerved as of the prime quality, it follows, that, unleſs the quantity of milk was, upon the whole, very conſiderable, the quantity of prime cream produced would be ſo ſmall, as to be ſcarcely worth the while of manufacturing ſeparately.

6thly. That, from theſe premiſes, we are alſo led to draw another concluſion, extremely different from the opinion that is commonly entertained on this ſubject; *viz.* That it ſeems probable that the very beſt butter could only be with economy made in thoſe dairies where the manufacture of cheeſe is the principal object. The reaſons are obvious: if only a ſmall portion of the milk ſhould be ſet apart for butter, all the reſt may be made into cheeſe, while it is yet warm from the cow, and perfectly ſweet; and if only that portion of cream which riſes during the firſt three or four hours after milking is to be reſerved for butter, the rich milk, which is left after that cream is ſeparated, being ſtill perfectly ſweet, may be converted into cheeſe with as great advantage nearly as the new-milked milk itſelf. But as it is not probable that many perſons could be found who would be willing to purchaſe the very fineſt butter made in the manner above pointed out, at the price that would be ſufficient to indemnify the farmer for his trouble in making it, theſe hints are thrown out merely to ſatisfy the curious in what way butter poſſeſſing this ſuperior degree of excellence may be obtained, if they chooſe to be at the expence: but for an ordinary market, he is ſatisfied, from experience and attentive obſervation, that if, in general, about the firſt drawn half of the milk be ſeparated at each milking, and the remainder only be ſet up for producing cream; and if that milk be allowed to ſtand to throw up the whole of its cream, even till it begins ſenſibly to taſte ſouriſh; and if that cream be afterwards carefully managed, the butter thus obtained will be of a quality greatly ſuperior to what can uſually be obtained at market, and its quantity not conſiderably leſs than if the whole of the milk had been treated alike. Among other reaſons that induced him to ſeparate about the half of the milk is the following. Whilſt he was employed in making experiments on milk, it chanced, that among his cows there was one which had miſſed having a calf that ſeaſon, and ſtill continued to give milk. Her milk, as is not uncommon in theſe circumſtances, taſted ſenſibly ſalt. On trying the different parcels of that milk, however, it was perceived that the firſt-drawn milk was extremely ſalt to the taſte, and that the laſt was perfectly ſweet. On an after-trial, made with a view to aſcertain what proportion of the milk was ſalt, it was found that the ſaltneſs decreaſed gradually from the beginning, and was entirely gone when near the half of the milk was drawn off, ſo that all the laſt-drawn half of the milk was quite ſweet. He intended to have tried if other nauſeous taſtes that ſometimes affect milks, ſuch as that from turnips, cabbages, &c. was particularly confined to the firſt-drawn milk or not; but other avocations prevented him from aſcertaining this fact. He, therefore, concludes,

concludes, that this is the practice which he thinks moſt likely to ſuit the frugal farmer, as his butter, though of a ſuperior quality, could be afforded at a price that would always enſure it a rapid ſale. In the extenſive and ſucceſsful practice of ſome butter dairies, it has been found beneficial, in the winter ſeaſon, to add hot water to the milk immediately as it comes from the cow, in the view of making it yield the cream more fully.

With regard to the degree of heat which is neceſſary for the due ſeparation of the cream, few trials have yet been made; but from what has been done, it is believed by Dr. Anderſon, that when the heat is from 50 to 55 degrees on Fahrenheit's thermometer, the ſeparation of the cream from milk, which is the moſt important operation of the dairy, proceeds with the greateſt regularity, and in the moſt favourable manner. It is, therefore, thought that this will be found to be the temperature that ought to be aimed at: but it is not pretended to decide with preciſion; a conſiderable degree of latitude, in this reſpect, may, perhaps, be allowable; from the beſt obſervations, it ſeems to be highly probable that when the heat exceeds 60 degrees, the operations become difficult and dangerous; and when it falls below the 40th degree, they can ſcarcely be carried forward with any degree of economy or propriety. Till farther experiments, therefore, aſcertain the exact point, it may, he thinks, be taken as a ſafe rule that the heat ſhould be kept up, if poſſible, between the 50th and 55th degree; and, in order to aſcertain this, a thermometer, graduated by Fahrenheit's ſcale, ſhould be hung up perpetually in the milk-houſe, to give notice to the owner of any alterations in the temperature of the air that may affect his intereſt.

It has not yet been aſcertained in any ſatisfactory manner, what is the length of time that the milk ſhould remain in the pans or trays, in order to afford the cream in the largeſt quantity before it is ſeparated. Some ſuppoſe that this ſhould depend upon the particular views of the dairy-man, and the degree of heat that is preſent at the period. In a moderately warm temperature of the air, if very fine butter be intended, it ſhould not be allowed, the Doctor ſays, to ſtand more than ſix or eight hours. For ordinary good butter it may ſafely be let ſtand twelve hours or more; but where the dairy is ſo large as to afford a ſufficient quantity of cream, and where the very beſt butter is intended, (the milk being to be converted to ſome other uſe while yet ſweet,) it may be ſeparated after ſtanding only two, three, or four hours. "In the general management of dairies, milk is, he ſays, never ſkimmed more than once; but in the county of Eſſex, as well as ſome others, it is the common practice to ſkim it three or four times, or till no more cream riſe. In the buſineſs of ſeparating the cream from the milk there are two methods purſued: that moſt generally practiſed is to ſkim it off with a ſkimming-diſh, made either of tin or of wood. The other is adopted only where leads or ciſterns are common, and where the milk is uſed for making ſkim milk or two-meal cheeſes; and, of courſe, before it coagulate, or acquire any degree of acidity. Towards the centre of the ciſtern there is a hole or pipe, which, before the milk be put in, is ſhut with a wooden ſtopper that riſes ſeveral inches above the ſurface of the milk. When the milk is wanted for any of the purpoſes above-mentioned, a veſſel is placed under the pipe, and the ſtopper drawn up ſo far as to allow the milk to run off, but ſo gently, as that the ſurface of the cream may not be broken. The milk being thus gradually drained off, the cream ſinks down, till it at laſt reſts on the ciſtern; when the veſſel containing the milk being removed, and another placed for the purpoſe of receiving the cream, the ſtopper is entirely drawn out, and the cream drops into the veſſel." The firſt of theſe methods, the Doctor ſays, "requires a dexterity of manipulation that can be acquired by practice alone; but it is of great importance to the ſucceſs of the dairy that it be well done; for, if any part of the cream be left, the quantity of butter will be diminiſhed, and if any part of the milk be taken, its quality will be debaſed."

After the cream has been "thus ſeparated from the milk, it ought to be immediately put into a veſſel by itſelf, to be kept till a proper quantity be collected for being made into butter: and no veſſel can be better adapted for that purpoſe than a firm neat-made wooden barrel, in ſize proportioned to the extent of the dairy, open at one end, with a lid exactly fitted, to cloſe it. In the underpart of this veſſel, cloſe to the bottom, ſhould be placed a cock, for drawing off from time to time any thin ſerous part of the milk that may chance to be generated; for ſhould this be allowed to remain, it acts upon the cream in a powerful manner, and greatly diminiſhes the richneſs of the quality of the butter. The inſide of the opening of the barrel ſhould be covered with a bit of cloſe fine wire, or ſilver gauze netting, to keep back the cream, while the ſcum is allowed to paſs; and the barrel on its ſtand ſhould be inclined a little forward in the top, to allow the whole to run off in a perfect manner.

In reſpect to the length of time it may be kept in theſe veſſels with advantage before it is churned, it is very different in different caſes; but about Epping, in Eſſex, according to Mr. Abdey, as ſtated in the Annals of Agriculture, which has been long in high repute for the ſuperior quality of its butter, "the cream is ſeldom kept above three or, at furtheſt, four days," but always till there is a certain degree of acidity in it, either natural or artificial, as without that they cannot inſure a good churning of butter; ſome keep a little old cream for this uſe, others uſe a little rennet, and ſome a little lemon juice. And it was practiſed in a large dairy in Suffolk, which had a high character for making butter of a ſuperior quality, when the butter was to be ſent directly to market, to churn the cream the ſecond or third day; but when it was to be ſalted, to keep it a day or two longer, or till it had acquired a certain degree of acidity. The dairy-woman, who had had a long and extenſive experience, accounted for her conduct in this reſpect, by obſerving that butter made from freſh cream was much better and pleaſanter to the taſte, but that it would not take in the ſalt ſo well, or keep ſo long, as that made from cream that had been longer kept. It has been ſuggeſted by Dr. Anderſon, that thoſe "who have had little experience in the dairy, believe that no butter can be of the fineſt quality, except that which has been made from cream that has not been kept above one day; but this is a very great miſtake. So far indeed is this opinion from being well founded, that it is in very few caſes that even tolerably good butter can be obtained from cream that is not more than one day old. The ſeparation of butter from cream only takes place after the cream has attained a certain degree of acidity. If it be agitated before that acidity has begun to take place, no butter can be obtained, and the agitation muſt be continued till the time that the ſourneſs is produced; after which the butter begins to form. In ſummer, while the climature is warm, the beating may be, without very much difficulty, continued, until the acidity be produced, ſo that butter may be got; but in this caſe the proceſs is long and tedious, and the butter is, for the moſt part, of a ſoft conſiſtence, and tough and gluey to the touch. If this proceſs be attempted during the cold weather in winter, butter can ſcarcely be in any way obtained, unleſs by the application of ſome great

degree of heat, which ſometimes aſſiſts in producing a very inferior kind of butter, that is white, hard, and brittle, with very little taſte, and almoſt unfit for any culinary purpoſe whatever." The intelligent dairy-farmer ſhould not of courſe attempt to imitate this practice, but allow his cream to remain in the veſſel appropriated for keeping it, until it has acquired that proper degree of acidity that fits it for being made into butter with great eaſe, and by a moderate degree of agitation; by which proceſs only very fine butter can be prepared. It is added that the exact length of time cream may be kept, before it attains the preciſe degree of acidity that is neceſſary to form the very beſt butter, and after that period before its quality be ſenſibly diminiſhed, has not yet been well aſcertained by any experiment that can be fully depended upon: "So little nicety," ſays the above writer, "has been obſerved in this reſpect by practical dairy-farmers, even thoſe who have a high reputation for making good butter, that few of them ever think of obſerving any preciſe rule in this reſpect, with regard to the different portions of their cream, ſeeing they in general make into butter all the cream they have collected ſince the former churning, ſo that the new and the old is all beaten up together; and he can find nothing like an uniform rule eſtabliſhed among them, as to the time that ſhould intervene between one churning and another, that being uſually determined by local or accidental circumſtances. He is himſelf inclined to believe, that if the cream be carefully kept, and no ſerous matter allowed to lodge about it, a very great latitude may ſafely be admitted in this reſpect;" and though the exact length of time has not been determined, "it is certain that cream which has been kept three or four days in ſummer, is in excellent condition for being made into butter;" and he is inclined to believe, that from three days to ſeven may be found in general the beſt time for keeping cream before churning; though, if circumſtances make it neceſſary, a conſiderable latitude in this reſpect may be allowed. If the farmer has ſuch a quantity of cream as may be worth his while to churn once every day, there is nothing to prevent him from doing it. He has only to provide a ſeparate veſſel for holding the cream for each day he means it ſhould ſtand before churning; if three days, three veſſels; if four days, four veſſels; and ſo on. Thus he may churn every day cream of three days old, or of four; or any other number of days old that he may incline. In the ſame manner, if it were found that the cream of two, of three, or of a greater number of days gathering, was required to make a proper churning, it might be eaſy ſo to contrive it as to churn every day, as will be obvious to any one who thinks upon the ſubject. In this manner, the operations of dairying may be kept perfectly regular and eaſy.

It is not an unuſual practice in Cheſhire to churn the whole of the milk without ſeparating any part of the cream from it. After milking, it is cooled in quantities according to the heat of the weather in ſummer, in ſeparate veſſels for the purpoſe, and a certain degree of acidity brought on. This is effected previouſly to its being put together, which is the caſe from time to time, in earthern cream mugs or jars. In theſe jars, which contain from four to ſix gallons each, it is ſuffered to ſtand till it is what is there termed *carved*, or clotted in a proper degree for churning, which is judged ſufficiently the caſe when the whole is coagulated and has acquired a ſmall degree of acidity, which commonly, in warm weather, takes place in the courſe of a day or two. And the cream is warmed in the winter by the mugs being ſet by the fire, in order to forward the *carving* or clotting of the milk. If the milk ſhould not have been ſufficiently cooled in warm weather, before it was put to the former meal, or if in the winter ſeaſon the mugs have been ſet too near the fire, the whole maſs becomes curdled, making, as they phraſe it, "go all to whig and whey," and to afterwards heave in the mug. And further, if in ſummer, or when kept in a warm ſituation, the milk is not churned within a day, or a little more, after it is ſufficiently *carved*, a kind of fermentation and heaving likewiſe comes on; in both caſes the butter will be rank and ill-taſted; nor will the milk afford ſo much butter, as when it has been properly managed and churned in due time. In this way they obtain a greater quantity of butter, though of an inferior quality. By careful management, however, eſpeciallv if a portion of the firſt-drawn milk be ſeparated, very good butter may, it is ſuppoſed, be obtained; but the practice, on many accounts, is not to be adviſed.

In the ſummer ſeaſon, or while the cows are fed on graſs, it is not requiſite to give butter that colour which is agreeable to the purchaſer or conſumer, by means of art; but in winter and ſpring months, the dairy people find it neceſſary, in order to pleaſe their cuſtomers, to alter that tallowy appearance, which is natural to butter in theſe ſeaſons, which is effected by means of a little arnotto, which, after being reduced by trituration to as fine a powder as poſſible, is blended and incorporated with the cream before it is put into the churn, in ſuch proportions as, from experience, has been found neceſſary for giving the requiſite appearance or colour to the product.

After thus deſcribing the different preparatory ſteps which are neceſſary to be regarded in the butter dairy, it will be proper to detail the practice which is uſually purſued in making that important article.

Making of Butter.

This is a product of the dairy, in the manufacture of which great nicety and attention are requiſite, as has been ſeen above, in order to have it of the beſt quality. It has been ſtated, that there are two methods purſued with the milk, with the view of procuring the butter from it. In one, the oily part or cream is ſeparated from the milk, and in that ſtate converted into butter, by means of agitation, in a proper veſſel; while in the other, the whole of the milk is ſubjected to the proceſs. The particular advantages of theſe different methods of practice have not been fully ſtated, nor have any comparative experiments, which we know of, been inſtituted with the view of aſcertaining, which of them has the ſuperiority in reſpect to the quantity and quality or flavour of the butter which is obtained. It is a point of management which, however, deſerves attention, and which is capable of being decided without much difficulty or expence in the experiments. The beſt mode has always appeared to us, to be that of uſing the cream in the ſtate of ſeparation from the milk, both in the convenience and the goodneſs of the butter.

Churning.

It is extremely evident that while the oily or butyraceous part of milk is in the ſtate of cream, the particles are not in a ſufficiently concentrated ſtate for producing an uniform ſubſtance, on account of the large portion of interpoſing ſerous fluid; conſequently, in order to produce butter, it is neceſſary to force out this fluid by means of continued agitation, a proceſs which is termed *churning*. In which the cream or milk, after being ſeparated and prepared in the above manner, is put into the churn of the kind which is preferred, as there are ſeveral different ſorts employed in different places and agitated for ſome time, in order to effect the ſeparation of the butter. And "from the practice gene-

rally

rally adopted in the beſt managed dairies of cooling the churn, by filling it for ſome time with cold water before churning in ſummer, and of warming it with ſcalding water when the weather is very cold in winter, and of putting in alſo cold or hot water among the cream in the churn occaſionally, according to the ſeaſon of the year," it is concluded by Mr. Donaldſon, "that cream poſſeſſing a proper temperature, whatever that temperature may be, is, among the moſt exact dairy-farmers, conſidered eſſentially neceſſary in the making of good butter; which being admitted, it muſt follow, that ſome churns may be better ſuited to the purpoſe than others:—As ſuch as admit a free ſupply of atmoſpheric air, and permit that which from the violent agitation has become over heated to eſcape, from their preſerving the medium temperature which, it would appear, cream, in the courſe of making into butter, ought to poſſeſs, than ſuch as are kept conſtantly ſhut up, or, in which the air is only allowed to enter or eſcape occaſionally by means of a ſmall aperture." The author of Practical Agriculture obſerves, that "it is probably on this account that the upright churn is ſtill preferred in ſome dairies."

And it is remarked, that in this proceſs, much greater nicety is required than moſt perſons ſeem to be aware of, as a few haſty irregular ſtrokes may render the whole of the butter of ſcarcely any value, which, but for this circumſtance, would have been of the fineſt quality. The owner of an extenſive dairy ſhould, therefore, be extremely attentive to this circumſtance, and be at great pains to procure a proper perſon for managing this branch of the buſineſs. See CHURNING.

In Cheſhire they moſtly employ churns of the upright kind in their dairies, which are in ſome inſtances improved by having a lever applied to them; in which caſes one end of it (which is ſupported by means of an upright frame) is connected with or attached to the end of the churnſtaff; the other end of it, being by means of a rod, connected with a crank in a toothed wheel, and worked by a pinion fixed upon the axis of a common winch. In this way the operation is capable of being performed with facility by a ſingle perſon. And in a ſingle inſtance Mr. Holland found a water wheel applied ſo as to work the churn; being ſo contrived as that the ſtaff of it can be made, at pleaſure, to give from one to a hundred and eight ſtrokes in a minute. And it is ſtated that the greateſt advantage has been experienced from this method of churning, ſo as to juſtify its introduction in all caſes where the ſituation of the dairy will admit of it. In the dairies of Glouceſterſhire they make uſe of both the hand and barrel churns, according to the quantity of butter which is to be made. See CHURN.

Preparation of the Butter.

When by the proceſs of churning, or keeping the cream conſtantly in a ſtate of motion, the butyraceous particles are ſeparated from the milk, and after being gathered and united to each other, the maſs is taken out of the churn and put into a large wooden bowl, or other convenient veſſel, with ſome cold ſpring-water which is perfectly pure; the dairy-maid preſſes and kneads it well with her hands, or, what is better, a wooden ſpoon with a ſhort handle, afterwards breaking it into as minute diviſions as poſſible; and, by rolling and preſſing it againſt the bottom and ſides of the baſon or other veſſel, expreſſes and forces out any milk that it may contain. Upon this being well performed, the goodneſs of the butter in a great meaſure depends. When it has been thus worked, the milky water is poured off, and an additional quantity of pure clean water put in; and the operations of kneading, breaking, and preſſing, are again renewed, and continued till the water which comes off at laſt appears ſcarcely tinged with milk, which is the only proper criterion by which to determine when the butter has been ſufficiently worked. And it has been obſerved, that a conſiderable degree of ſtrength, as well as of dexterity, is required in this manipulation. The principal thing wanted, is to force out the milk entirely, with as little tawing of the butter as poſſible; for, if the milk be not entirely taken away, the butter will infallibly ſpoil in a ſhort time; and if it be too much worked, the butter will become tough and gluey, which greatly debaſes its quality. Another method of making butter, practiſed in Holland, as ſtated by Mr Carew, in the "Agricultural Report of Middleſex," is this:—After milking the cows, the milk is put into pans till it is quite cold. It is then ſtirred two or three times a-day with a wooden ſpoon, to prevent the cream from ſeparating from the milk; and if it can be ſtirred till the ſpoon will almoſt ſtand in it, it is deemed ſo much the better. When it is found to be ſufficiently thick, it is put into the churn; and beaten for an hour. When the butter begins to form, a pint or more of cold water, according to the quantity of the milk, is poured in, to ſeparate the butter from the milk. When the butter is taken out of the churn, it is waſhed and kneaded till the laſt water is perfectly clear and free from milk. By this method it is ſuppoſed, that a greater quantity of butter is made from an equal quantity of milk; and the butter is ſaid to be firmer and ſweeter, and to keep longer, than that which is made in the ordinary mode which is in uſe in this country. The butter-milk is alſo thought preferable, and a churn is there thought better adapted to the purpoſe than a barrel. But in either method, good butter may be made with due care and attention.

A ſmall quantity of ſalt in moſt caſes is mixed with butter, even which is attended for immediate uſe; and when the butter is ſalted, whether it be with a view to keeping or for immediate ſale, the ſalt is applied as ſoon as the milk has been extracted or removed in the manner deſcribed above. Part of the butter is ſpread on the bottom of another baſon or ſkeel, which has been previouſly waſhed and prepared for the purpoſe; and a quantity of ſalt being ſtrewed over it, an additional layer of butter is then laid on; over this, another ſprinkling of ſalt, and ſo on alternately till the whole be ſalted to the proper degree, according to the uſe for which the butter is intended. When the whole is thus ſalted, the dairy-maid again preſſes, kneads, breaks, and works it in ſuch a manner as to make the ſalt mix intimately with it; and when ſhe thinks ſhe has fully effected this purpoſe, ſhe pours ſome ſpring or other cold water over the whole; and, by again working the butter, waſhes it free from the brine, and from any milky ſubſtance, which, by the ſalting, and the repetition of kneading, preſſing, &c. may have been expreſſed.

When theſe different operations of butter-making have been performed, all that remains neceſſary to be done is to weigh and make it up into the form in which it is moſt ſaleable. The uſual form in which it is expoſed to ſale is in rolls; but it is ſometimes made into circular cakes of about three or four inches diameter, and about an inch thick, and on the top of which figures are impreſſed by means of a wooden print carved for the purpoſe.

In moſt of the Cheſhire dairies the butter made up for ſale is formed into lumps, which are there termed *diſhes*; the weight of one of which is one pound and a half, or twenty-four ounces. In Lancaſhire the butter is uſually formed into pounds of ſixteen or eighteen ounces, in a round flat manner, with the impreſſion of a figure upon the top.

But in many of the midland and ſouthern dairy diſtricts, it is common to make it up, for the London market, into *lumps* of two pounds each.

After the butter, in well-managed dairies, is weighed and made up for market, it is uſually placed in cold water till the period for ſending it to market takes place.

In regard to the quantity of butter produced from a given quantity of milk, it depends on a variety of minute particulars: as the quality of the milk, the age and quality of the paſtures on which the cows are maintained, and whether the milk be allowed to ſtand a ſufficient time to throw up the whole cream which it contains. But, on a medium, four gallons of milk will produce ſixteen ounces of butter; and the quantity which a dairy of cows of any magnitude, in regard to numbers, may be ſuppoſed to yield, may be rated at ſix pounds each *per* week in ſummer, and from four to five in winter, according to the manner of feeding them. In Suffolk they find that four gallons and a half of milk afford a quart of cream, which, when made into butter, weighs one pound and three-quarters. And Mr. Abdey, in the Epping practice, found the avarage quantity of butter made by a cow *per* week, to be four pounds, of ſixteen ounces, and the whole in nine months, one hundred and fifty-ſix pounds; beſides the advantage of ſix ſhillings a piece for three pigs which were kept. His ſtatement, as given in the Annals of Agriculture, is this:

	£.	s.	d.
156 *lbs.* at 10 *d. per lb.* -	6	10	0
Calf, - -	0	18	0
3 pigs, - -	0	18	0
	8	6	0

But at the preſent price.

	£.	s.	d.
156 *lbs.* at 1 *s.* 3 *d. per lb.*	9	15	0
Calf, - -	1	5	0
3 pigs, - -	1	10	0
	12	10	0

In the Lincolnſhire Report on Agriculture, the average quantity of milk which affords a pound of butter is ſtated to be eighteen quarts, where the hand-churn is employed, and fifteen quarts by the horſe one. But in the accurate trials of J. C. Curwen, eſq. M.P., where oil-cake, in a ſmall proportion, was made uſe of in feeding the cows, and a pendulum churn conſtructed by Mr. M'Dougall employed; eight wine quarts of the ſtrippings, and nine quarts and a half of a mixture of the whole milk, were found to give a pound of butter. This ſtriking difference in the quantities is accounted for, partly from the large proportion of heifer's-milk, but more particularly from the uſe of the oil-cake in feeding the cows.

There is an inferior ſort of butter often made from whey, where cheeſe is the principal object of the dairy-farmer. The modes of conducting the proceſs in this caſe are ſtated by Mr. Donaldſon in the following manner: "In ſome dairies the whole whey, when taken from the cheeſe-tub is," he ſays, "put into ſkeels or other veſſels, where it remains about twenty-four hours; when it is creamed, and the whey applied to the uſe of the calves and pigs, the latter of which are ſaid to thrive as well on it after the cream has been taken from it as before. And the cream, when ſkimmed off the whey, is put into a braſs pan and boiled, and afterwards ſet in pans or jars, where it remains till a ſufficient quantity for a churning be procured, which in large dairie happens generally once, but ſometimes twice in the week." In others, "the green whey is put almoſt immediately from the cheeſe-tub into the furnace-pan, where it is ſcalded. When it acquires the proper degree of ſcalding-heat, cold water, or ſome white whey, is occaſionally put in; this cauſes the whey to break, and throw up a thick white ſort of ſcum, ſomewhat reſembling cream, which the dairy-maid keeps conſtantly ſkimming off as it riſes, and which ſhe puts into cream jugs or jars, where it remains till the uſual time of churning. In the dairies where the green whey is ſcalded, the runnings, except a little that is kept for the purpoſe of forcing the green whey when ſcalding to throw up the cream, are uſually ſet in ſkeels or jars, in the ſame manner as the milk from the cows, and the cream when taken off being added to that procured by ſcalding, is churned in the ordinary way." In the Cheſhire dairies, the *thruſtings* or white whey is in ſome caſes ſet in cream mugs to *carve*, and acidulate for churning, either by the warmth of the ſeaſon, or of a room, in the ſame manner as in making milk butter. But in other caſes the green and white whey are both heated together, in which caſe, or when the green whey is heated alone, (where the boiler is of iron, it is previouſly rubbed with butter to prevent the whey from *catching* or acquiring a burnt-like taſte) ſuch a fire is kept as will make the whey as hot as poſſible, without boiling; and as ſoon as that degree of heat has been acquired, the buttery matter, which the whey contains, breaks or ſeparates from it, and riſes to the ſurface. This commonly takes place in the courſe of about an hour; but when the whey is perfectly ſweet, a little ſouring is ſometimes added to produce the breaking effect.

But in the Glouceſterſhire dairies, according to Mr. Rudge, the whey is immediately "removed from the tub or cowl into the receivers, which are made of an oblong ſquare form, ſix or ſeven feet long, three wide, and from four to ſix inches deep, with a tap-hole in ſome part of the bottom to draw it off. The inſide is lined with lead, and this aſſiſts in keeping up a great coolneſs, ſo neceſſary in the hot months; for if it were left to a high ſtate of temperature, it would become ſour in a few hours; but in this way it will ſtand for twenty-four hours, and during that time it is generally ſkimmed twice at leaſt." The cream being churned in the uſual manner for butter, and the whey given to the hogs.

But in two experiments made for the purpoſe of aſcertaining the nature of making butter from whey, Mr. Robertſon found the reſult the ſame, though the proceſs was differently conducted. In one the whey had ſtood four-and-twenty hours after being taken from the curd before it was put to the fire; but in the other it was put on quite warm and freſh immediately from the curd; the quality as well as quantity were alike in both theſe methods.

It is aſſerted that the quantity of butter procured from whey is conſiderable; in two inſtances, where particular attention was beſtowed to aſcertain the fact, it was not leſs than about an ounce and a half from the gallon. In regard to the quality, it is unqueſtionably inferior to that of butter, made from the cream of milk, or from the milk and cream churned together, but not ſo much ſo as ſtated by Mr. Marſhall in his "Rural Economy of Glouceſterſhire," which is one-third. In the Report of the County of Leiceſter, it is indeed obſerved, "that whey butter ſells for nine-pence per pound, when other butter ſells from ten-pence to eleven-pence, and alſo, that eighteen cows will make about ſeventeen pounds, ſixteen ounces each, of whey-butter per week; which is a circumſtance Mr. Donaldſon thinks "that certainly merits the attention of thoſe who are in the practice of making either *one-meal* or *two-meal* cheeſes."

In

In the dairy practice of Cheſhire, where it is the cuſtom to churn up the whey-cream three times in the week, the average produce of butter, which is afforded by "one dairy cow," is from eight to ten ounces weekly. And the difference of price from it and that of milk-butter is from a penny to two-pence the pound. But in Glouceſterſhire it is ſtated to be three-pence in the pound inferior to milk-butter in the value at market.

Making of Cheeſe.

This is a practice which requires much care and attention in the dairy-farmer, in order that the proper profit may be derived from it. There are many different ſorts of cheeſe, as has been noticed in ſpeaking generally of the nature of cheeſe. In ſome of the principal diſtricts, where this article of food is made, they divide the kinds into the "*beſt making one meal*," or "*coward*," *two meal* and *ſkim cheeſe*. The firſt of theſe ſorts ſhould be made of the whole meal of milk; but a portion is often ſet by, to be ſkimmed for butter at the next milking, and the milk then added to the new meal, from which a ſimilar quantity is taken as before. This ſort of cheeſe is moſtly made in the county of Glouceſter, and is either thick or thin, the former being uſually termed *double Glouceſter*, having about four to the hundred or ſometimes fewer; and the latter about eight to the hundred weight. See CHEESE.

The ſecond, or two meal kind, is commonly made of one meal or portion of "coward," or clean milk, and one of ſkimmed, but ſometimes two portions of the latter are employed.

The third or ſkim-cheeſe is chiefly made where the main object is butter, and in which the milk is uſed after being two or three times ſkimmed.

While the cows are at hay the beſt-making cheeſe is never attempted.

In this ſort of proceſs, as in moſt of the other operations of dairying, there is a want of neceſſary accuracy and preciſion, as few experiments have been made, and thoſe without much nicety or exactneſs, the whole being in a great meaſure conducted at random by mere cuſtom. The ſame points of management are eſſential in all dairies, but they differ greatly in the minute particulars, on which much depends. The circumſtances that demand attention in a more particular manner are, however, the ſeaſon; the method of milking; the nature of the milk; the preparation of the rennet; the mode of colouring; the breaking and gathering of the curd; the management of the cheeſe in the cheeſe-preſs; the method of ſalting; the management in the cheeſe-room; and ſome miſcellaneous circumſtances concerning its preſervation.

Proper Seaſon.

With reſpect to the firſt, the beſt ſeaſon is during thoſe months when the cows can be fed on the paſtures; that is, from the beginning of May till towards the end of September, or, in favourable ſeaſons, the middle of October. On many of the larger dairy-farms in ſeveral diſtricts, cheeſe is frequently made throughout the year; but that made during the winter months is ſaid to be conſiderably inferior in quality, and much longer in becoming fit for ſale, or for uſe, than that which is made within the above period. In Glouceſterſhire the ſeaſon of making thin cheeſe is moſtly from April to November; but the principal one for making thick is during the months of May, June, and the beginning of July. This is the buſy ſeaſon of the dairy. If made later in the ſummer, they are found not to acquire a ſufficient degree of firmneſs to be marketable the enſuing ſpring. But where the cows are well fed in the winter ſeaſon, in the manner directed above, good cheeſe may undoubtedly be made at that time by proper care in the management.

Times of Milking.

In regard to the ſecond head, or the times of milking the cows, they are different in different cheeſe-diſtricts. In Cheſhire they are, in the ſummer ſeaſon, at ſix o'clock both morning and evening; and in winter, at day-light in the morning, and immediately before dark in the evening. But in Glouceſterſhire, Wiltſhire, Suffolk, and ſome other counties, the people are frequently employed in milking by four o'clock in the morning in ſummer; and the buſineſs in a dairy of forty or fifty cows is nearly completed before the period at which it commences in Cheſhire. The latter would ſeem on many accounts the moſt preferable practice; as when the cows are brought home to the farm-yard, which is the beſt method, where the paſtures are within a ſhort diſtance, they are milked unfettered, and the buſineſs is over before the heat increaſes ſo much as to make the cows reſtleſs and unruly. The farmer himſelf, or ſome careful perſon, ſhould always attend the milking of the cows, for the double purpoſe of ſeeing the work properly done, and carrying the milk in large buckets, into which it has been occaſionally emptied from the pails to the dairy, to be poured through a ſtrainer into coolers for the purpoſe, or the cheeſe-tub, preparatory to applying the rennet. In all well-managed dairies, particular attention ſhould be paid to the thorough milking of the cows; as where this is omitted, the cows are not only apt to go dry, but become more liable to be diſeaſed; beſides, it has been ſhewn, that the laſt part of the milk is very greatly ſuperior in quality to that which is firſt drawn from the bag, and conſequently ſhould be preſerved as much as poſſible.

The expeditious cooling of the milk, which in Cheſhire is effected by putting it into leaden coolers, is found of much utility in retarding the proceſs of fermentation in the ſummer ſeaſon, and thereby preventing the milk from turning into a ſtate of acidity. But in winter it is obviouſly unneceſſary. Theſe coolers are framed ſo as to reſt on legs in the manner of a table, the leaden ciſtern being at the top, and about nine inches in depth, five feet in length, and two feet and a half in width, having a vent-hole in the bottom, to which is fitted a wooden ſpiggot or plug. In ſome caſes they are ſufficiently large to hold a full meal's milk; in which caſes the milk ſtands in them all night, and after the cream is ſkimmed off in the morning, it is drawn out through the vent-hole into braſs-pans, and thus carried to the cheeſe tub. But where there is only one cooler, and that inſufficient to contain a meal's milk, it is the cuſtom to draw it off into pans, as ſoon as the cooler becomes full, which is again filled as the milk is brought to the houſe; that laſt brought in, being ſuffered to ſtand all night in the cooler. In other diſtricts, when the weather is only ſufficiently warm, the milk is ſuppoſed ready for uſe after being ſtrained; but when of too high a temperature, it is left to ſtand till properly cool; and in caſes where it is too cool, a proper quantity is warmed over the fire to raiſe the temperature: the grand buſineſs being, it is obſerved, to raiſe or lower it, to a ſuitable degree of warmth; as when it is too hot, it is liable to break up in knobs; and when too cold, it does not coagulate in a free manner.

It has indeed been ſuggeſted as probable that in very hot ſeaſons the cheeſe might be improved in its quality, and the difficulty of making it be leſſened, by cooling down the milk

as quickly as poſſible, by repeatedly drawing it off, and returning it again to the cooler or ciſtern.

Quality of the Milk employed.

The ſtate and qualities of the milk which is made uſe of in ſome cheeſe-diſtricts, in making different ſorts of cheeſe, has been noticed above. There can be little doubt but that much of the goodneſs of this article, under ordinary management, muſt depend upon the quality of the milk which is employed in making it. There is, however, conſiderable diverſity in the proportion of cream that is withdrawn from the milk employed in the making of cheeſe, in different caſes, and eſpecially according as they are *one* or *two-meal* kinds.

In the making of Cheſhire cheeſe, two meals milk is in common had recourſe to, even in dairies in which two cheeſes are made in the day: and in the beginning and end of the ſeaſon, three, four, and even five or ſix meals milk are reſerved for the ſame cheeſe. It is ſuggeſted as difficult to aſcertain what proportion of the cream is withheld from the milk, before it is put together; as the quantity may be varied, either through ſuppoſed judgment and ſkill in the art, or from motives of a different kind. In the beſt dairy-practice the cuſtom is to take about a pint of cream, where two-meal cheeſes are made, from the night's milk of twenty cows. It is, however, admitted, that with the view of making cheeſe of the beſt quality, the cream ſhould be ſuffered to remain in the milk; but it is an undecided point, whether ſuch cream as has been once ſeparated from it, can again by any means be ſo intimately combined with it, as to undergo no decompoſition in the after-management of the buſineſs. At leaſt there is no impropriety in endeavouring to prevent the ſeparation of two ſubſtances, which are again to be united. If a cheeſe made wholly of the night's milk, on which the cream has riſen, be as rich as one made of new milk, all the other circumſtances being the ſame, it is a proof that milk and cream, after being ſeparated, may, by heating alone, become as it were new milk again The point can, however, only be decided by the teſt of experiment. The practice here is, however, as will be ſeen, to unite the milk and cream; in which caſe the dairy-men ſuppoſe it differs in nothing, ſo far as the making of cheeſe is concerned, from new milk.

In the making of the cheeſe, the milk managed in the manner directed above is carried either in the evening or morning, but more commonly the latter, to the cheeſe-tub: ſometimes in making two-meal cheeſes, a portion of the creamed evening's milk is reſerved, as a half, a third, or more frequently only three or four gallons, to be uſed in this manner: after being made ſcalding hot, by being placed in a braſs pan over a furnace, or in a veſſel of hot water, one half of it is poured into the cheeſe-tub among the cold milk, and the remainder into the pan in which the cream had been placed. Then, on the cream and hot milk being intimately blended, the whole is poured into the cheeſe-tub, the contents of which have now been conſiderably increaſed by a great part, if not the whole, of the morning's milk warm from the cows. In this way the different meals milk conſtitutes, as it were, a fluid of the ſame nature, equal in quality and temperature. This ſort of re-union, or *melting the cream*, as it is termed, is perhaps the beſt method practiſed, though it is ſuppoſed not ſo effectual in affording cheeſe of the beſt quality, as that wholly by means of new milk.

But in the making of the inferior ſorts of cheeſe, as thoſe of the ſkim-milk kind, when the milk has been managed as ſtated above, where there is a tendency to too much acidity, inſtead of placing it over the furnace to afford it that degree of heat which is ſuppoſed neceſſary for facilitating the coagulation, after the application of the rennet as is uſual, it is the practice to put it directly into the cheeſe-tub, and to pour in hot water ſo as to procure the deſired temperature, without the riſk of its breaking while over the fire, and thus to avoid other inconveniences.

To the milk in theſe ſtates the rennet is immediately applied; but in the latter caſe a ſomewhat larger proportion is required, than in caſes of the ſame quantity of milk, where the whole, or a large part of the cream, is contained.

Preparation of the Rennet or Steep.

The coagulation or curdled ſtate of milk is capable of being produced by the uſe of any ſort of acid, but the material moſt commonly employed for the purpoſe, in the cheeſe-dairy, is the *maw-ſkin*, or ſtomach of a young ſucking calf, after it has undergone a ſuitable preparation. In this ſtate it is uſually termed *rennet* or *ſteep*. Theſe ſkins, on being procured from the butcher, uſually contain a curdled ſort of ſubſtance, which, on their being opened, is removed, and with the bag carefully and repeatedly waſhed in cold water, and then replaced in its former ſituation with a conſiderable portion of ſalt, the whole being then packed in an upright pan or jar, and a very ſtrong brine of ſalt and water poured over them. The bags or ſkins are frequently left in this ſtate for a whole year before they are made uſe of; but in other caſes, when they have remained ſome time covered with the brine, they are taken out, and on an additional quantity of ſalt being applied, they are hung up in the dairy, or other convenient place, to dry, and remain in that ſtate till they are made uſe of.

In the Cheſhire cheeſe-dairies, the following is conſidered as an improved method of managing this buſineſs. The whole of the ſkins for the ſeaſon, pickled and dried in the manner above, are put into an open veſſel or veſſels, and three pints of pure ſpring water poured in for each ſkin; they are then ſuffered to ſtand about twenty-four hours: the ſkins are then taken out, and put into other veſſels, adding for each one pint of ſpring water, letting them ſtand twenty-four hours as before. On taking the ſkins out the ſecond time, they ſhould be gently ſtroked down with the hand into the infuſion. They are now done with. The two infuſions, thus prepared, are now to be mixed together, paſſing the whole through a fine linen ſieve, and adding a quantity of ſalt ſomewhat more than is ſufficient to ſaturate the water, or till a portion of it remains at the bottom of the veſſel undiſſolved. The day following, and during the whole ſummer through, the ſcum is to be taken clearly off as it is formed; and as the liquor ſhould not be ſuffered to remain without a portion of undiſſolved ſalt at the bottom, it will be neceſſary to make frequent additions of freſh ſalt, as that which is diſſolved is gradually formed into cryſtals on the ſurface, and taken off with the ſcum as it riſes. In this ſtate the liquor is fit for uſe. There are ſome other modes of preparing rennet in uſe, but they do not differ materially from the above.

From the preparation in the firſt of theſe modes being made at different times, there muſt of neceſſity be a great difference in the ſtrength, and conſequently in the effects which are produced either when made uſe of in the piece, or after being ſteeped in ſome liquid. There is without doubt much more certainty in reſpect to the equality of ſtrength where the ſubſtance is extracted from the whole at once.

The quantity of the firſt ſorts of ſteep which is employed is uſually about the ſize of half a crown to a cheeſe of

ſixty

ſixty pounds, where it is cut from the bottom parts of the bags which are good; but when cut from other parts ten times as much is often inſufficient. The cuſtom commonly adopted is, to cut two pieces for each cheeſe; one from the inferior or bottom, and the other from the upper part of the ſkin. The cup in which the ſkin is infuſed, ſhould daily have a good ſcalding. Of the liquid preparation ſomething leſs than a wine half-pint will commonly be found ſufficient for a cheeſe of the ſame ſize as the above. And conſtantly, on taking any of the liquid out for uſe, the whole ſhould be well ſtirred up, in order that its ſtrength may be more equally preſerved.

In Glouceſterſhire, the proportion of rennet employed is one-third of a pint to fifty gallons of milk, which quantity is ſuppoſed to make three cheeſes of from ten to a hundred weight, or of 33 pounds each.

Cheeſe colouring.

The uſe of this ſubſtance has been ſo long common in moſt of the cheeſe diſtricts, that it is probable the article would be almoſt wholly unſaleable without it, eſpecially the beſt kind. This is a practice which, probably, had its origin in the deſign of affording the idea of richneſs; but it is conſtantly found that the leaneſt cheeſe requires the largeſt quantity of colouring matter, to bring it to that appearance which is deſired. And the degree of colour is moſtly regulated by the name under which the cheeſe is intended to be ſold by. The ſubſtance which is employed for this purpoſe ſhould be Spaniſh *arnotto*, but is often a matter of an inferior quality. Where it is of the genuine kind, the weight of a guinea and a half is moſtly ſufficient for a cheeſe of ſixty pounds weight; but in the Glouceſterſhire dairies, they allow an ounce commonly to a hundred weight of cheeſe. In preparing it for being mixed with the milk, different methods are purſued. In the Cheſhire dairies, the quantity ſuppoſed neceſſary is uſually tied up in a linen rag, and put into half a pint of warm water over night, when to be uſed in the following morning; the whole of the infuſion being then blended with the milk in the tub, at the ſame time that the ſteep infuſion is applied, dipping the rag into the milk, and rubbing it againſt the palm of the hand as long as any colour can be made to come from it. But in Glouceſterſhire, it is prepared by carefully rubbing a piece of it upon a ſtone kept for the purpoſe, and then mixing it in a liquid ſtate with the milk. The quantity is here judged of by the ſhade of the colour to be produced, without any fixed rule; and it is put in previouſly to the application of the rennet. As this is an uſeleſs and ridiculous practice, which adds nothing to the qualities of the cheeſe, it ſhould ſurely be ſet aſide.

Setting the Cheeſe-Curd.

It is far from being aſcertained with any degree of accuracy what the temperature of the milk ſhould be, in order to be in the moſt proper ſtate for the application of the rennet. It is, however, generally allowed that the quantity as well as quality or texture of the curd, in ſo far as toughneſs, or the contrary, is concerned, depends in a great meaſure on the length of time the curd is in forming; and that again on the quantity and ſtrength of the coagulation or ſteep employed, the ſtate of the atmoſphere, and the heat of the milk, at the time of being mixed together. In this point, the practice of almoſt every particular dairy differs from that of the other. In thoſe of Cheſhire, the *loweſt* degree of heat which milk ſhould have, when the rennet is applied, is ſuppoſed to be one-half of that of the milk from the cow; the *higheſt*, about twice the natural warmth. From this it is inferred, that by the time a large dairy of cows has been milked, and the milk put together for the purpoſe of artificial coagulation, the dairy manager will not commit any material error in applying the rennet immediately afterwards. This is, however, a rule which is uncertain, and open to much objection from the variation of the ſeaſon, and the frequent great changes which take place in the ſtate of the weather in the ſame ſeaſon. Conſequently, in all dairies which afford cheeſe of a ſuperior quality, the heat of the milk is brought to the regular ſtandard which has been ſuggeſted by experience as the moſt ſuitable, before the rennet is applied. It is likewiſe found, as the reſult of experience, that the milk, produced on poor clays, requires more warming than ſuch as is afforded on lands that are rich; as where this is much heated, the difficulty of the proceſs is increaſed. In ſome Cheſhire dairies they do not, however, heat a drop of the evening's milk, only diſſolving the cream in a braſs pan floated in a furnace of hot water. It is ſuppoſed by Mr. Rudge, from ſome experiments which have been made, that the proper degree of heat is about the middle between ſummer and blood heat, or probably about 90° of Fahrenheit's thermometer may give the average warmth which is neceſſary.

Some highly intereſting and important obſervations and experiments, made with the view of aſcertaining this matter, have been ſtated by Mr. Marſhal in the following manner.

Next, ſays he, to the art of correcting the milk (an art as yet in its infancy), that of coagulating it, ſeems to claim the attention of the experimentaliſt. It is known, from daily experience, that the warmer the milk is, when the rennet is put to it, the ſooner it will coagulate, with a given quantity of rennet of a given ſtrength. It is equally well known, that the cooler the milk, and the longer it is in coagulating, the more tender and delicate the curd becomes: on the contrary, if the milk be too hot, and the coagulation takes place too rapidly, the curd proves tough and harſh. But it ſeems to be a fact equally well eſtabliſhed, that a cheeſe made from milk which has been coolly and ſlowly coagulated, is longer before it becomes marketable, than one made from milk which has undergone a leſs deliberate coagulation; and which, being drier and of a harſher texture, ſooner becomes cheeſey, and fit for the taſter. Therefore, the great art in this ſtage of the proceſs lies in the degree of warmth of the milk when ſet; that is, when the rennet is put to it; or, in the degree of heat retained by the curd when it comes, that is, when the coagulation has ſufficiently taken place, or, in the length of time between the ſetting and coming: which length of time may regulated either by the degree of the warmth of the milk when ſet; or, by the ſtate of warmth in which it is kept during the time of coagulation; or, by the quantity and ſtrength, taken jointly of the rennet.

In order to gain ſome information on this ſubject, he made the following experiments.

In 1781, June 5th, twenty-three gallons of milk, heated to ninety-ſix degrees of Fahrenheit's ſcale, with two tea-cupfuls of weakiſh rennet, came in one hour; the curd delicate and good: 6th, the ſame quantity of milk, of the ſame heat, with the ſame quantity of rennet, came in nearly the ſame time: the curd ſomewhat tough; owing, probably, to the milk having been burnt to the kettle in which it was heated: 7th, twenty-ſeven gallons of milk, heated to ninety-four degrees, with the ſame quantity of rennet, came in about two hours; the curd very good: 8th, twenty-ſix gallons of milk, heated to one hundred and two degrees, with one tea-cupful of rennet, came in two hours and a half;

half; curd very good: 9th, twenty-five gallons of milk, heated to one hundred degrees, with a tea-cupful and a half of rennet, came in about one hour and a half; the curd good, but ſomewhat tough, owing, perhaps, to the milk being kept too warm in the cheeſe-tub, by being covered up cloſe with a thick cloth.

It is noted, that on the ſeventh and eighth the whey retained the heat of about eighty-eight degrees, whereas the whey this morning was ninety-two degrees: ſo that, perhaps, it is not the heat when it is ſet, but the heat when it comes, which gives the quality of the curd: 10th, twenty-five gallons; ninety-ſix degrees; two cups; uncovered; came in two hours and a quarter; whey eighty-ſeven degrees; curd very tender: 11th, twenty-three gallons; one hundred degrees; more than a tea-cup; uncovered; did not come in two hours; owing to the rennet being lower in ſtrength than before; therefore, added a little more rennet, which brought it in about three hours from firſt ſetting; the whey eighty-ſeven degrees; the curd uncommonly delicate: 12th, twenty-four gallons of milk; one hundred degrees; two cups of rennet; uncovered; came in two hours; whey eighty-nine degrees; curd uncommonly tender: 13th, twenty-eight gallons of milk; ninety-two degrees; three cups, (ſay ſtrongly renneted;) covered up with a coarſe linen cloth; came in one hour and a half; whey eighty-ſix degrees; curd very good, and of a very fine colour; though perhaps would have handled tenderer if it had not ſtood ſome time after it came, before it was broken up. Perhaps, ſays he, much depends on its being broken up in the critical minute: 14th, twenty-eight gallons; one hundred degrees; two cupfuls; uncovered; came in one hour and a quarter; whey ninety-four degrees; curd ſomewhat harſh, but of a good colour. The change of colour, therefore, he thinks, owing to the change of paſture.

Here he notes, that the milk ſhould be covered to make it come together; this came, and grew hard at the bottom half an hour before it was ſet at the top: 15th, twenty-eight gallons; milk heated to ninety-five degrees; with two cups of rennet; and covered after it had ſtood three quarters of an hour; came in one hour and a half; whey eighty-nine degrees, (the morning warm;) curd very good and tender: 16th, thirty gallons of milk heated to one hundred and three degrees, but lowered by two pails-full of cold water to ninety-ſix degrees; with two cups and a half of rennet; and kept cloſe covered; came in an hour; whey ninety four degrees; curd pretty good, but not ſufficiently tender: 17th, twenty-eight gallons; ninety-ſeven degrees; two cups and a half; covered, but not cloſe; came in one hour and a half; whey not tried, curd ſomewhat tough.

It is noted that the toughneſs was owing, perhaps, to ſome milk of a new-calved cow being among it. But to try the exact heat of milk immediately from the cow, he immerged a diſh in the pail while milking. After it had lain long enough to receive a degree of heat equal to that of the milk in the pail, emptied it, and immediately milked into it from the teat, (the cow being at the time about half milked;) the heat ninety-five degrees; and likewiſe, that the cheeſes of yeſterday (the 16th of June) preſs remarkably elaſtic, and ſpongy, like a fungus, perhaps owing to the milk's coming too hot; or, perhaps, to two or three of the cows being then a-bulling; or, perhaps, being made thicker than uſual, the preſs was not heavy enough for them; or, perhaps, this ill quality is owing to the cold water being put into the milk.

He afterwards found, that milk of a cow, on the day of amour, retained, after having ſtood ſome time in the pail after milking, ninety-eight degrees of heat. This ſhews that the ſtate, if not the quality of the milk, is altered by the heat of the cow; and a cautious dairy-woman always endeavours to keep ſuch milk out of her cheeſe-tub.

June 18th, thirty gallons; ninety-five degrees; covered; came in an hour and a half; whey ninety-two degrees; curd pretty good: 19th, thirty gallons; ninety-two degrees; two cups; covered; curd very good: 21ſt, thirty gallons; ninety-eight degrees; lowered by half a pail of cold water to ninety-five degrees; the curd good; but the cheeſes, like thoſe of the 16th, preſs hollow and ſpongy. Therefore, it is probable, from theſe two incidents, that lowering the heat of the milk with cold water has an evil effect: 23d, (evening) fifteen gallons of new milk warm from the cow, retaining a heat of ninety-two degrees; with two cups and a half of new weak rennet; and cloſely covered; came in three quarters of an hour; whey eighty-eight degrees; curd very delicate and good: 25th, forty gallons of half ſkim-milk, heated to eighty-ſeven degrees, with three cups of rennet, ſlightly covered, came in three quarters of an hour; whey ſeventy-nine degrees; curd remarkably good of this ſort.

On September 8th, in obſerving the effect of ſome remarkably ſtrong rennet, he found that an ordinary tea-cupful coagulated ſufficiently upwards of forty gallons of milk, heated to only eighty-eight degrees, in thirty-five minutes.

From the whole of theſe experiments it appears, he thinks, that curd of a good quality may be obtained from milk heated from 87 to 103 degrees of Fahrenheit's thermometer, provided the rennet be ſo proportioned, that the time of coagulation be from three quarters of an hour to two hours and a half; and provided the milk be kept properly covered during the proceſs of coagulation. And from theſe, as well as a variety of other trials, which he made in the courſe of the ſummer, it appears to him at preſent, that from 85° to 90° are the proper degrees of heat; that from one to two hours is the proper time of coagulation; and that the milk ought to be covered, ſo as to loſe in the proceſs about five degrees of its original heat. But, ſays he, climature, ſeaſons, the weather, and the paſture, may require that theſe bounds ſhould ſometimes be broken. A few obſervations, made in one ſeaſon, and in one place, how accurately ſoever they may have been taken, are by no means adequate to the entire illuſtration of this very abſtruſe ſubject.

It has been ſtated as a matter of ſurpriſe, by Mr. Donaldſon, that in dairies of conſiderable extent, the uſe of the thermometer is not ſo well underſtood as that of the *ſkimming-diſh*, as by correct trials in this way, in reſpect to the moſt ſuitable temperature for milk, in order to have the rennet applied, the quality of the cheeſe might be greatly improved, and the bad conſequences of cracking, bliſtering, and hoveing which often take place from improprieties in the making, be prevented. An inſtrument termed a lactometer has likewiſe been invented, in the view of rendering aſſiſtance in this way, by Mr. Dicas of Liverpool, by the uſe of which, and the thermometer, it is imagined, by the above writer, that conſiderable improvement would be made in the management of the cheeſe-dairy, eſpecially, if at the ſame time a mean could be eſtabliſhed for determining the ſtrength and quality of the rennet, and the quantity neceſſary for properly coagulating a given quantity of milk. See LACTOMETER.

The frothy ſubſtance which is apt to riſe in pouring the new milk into the cheeſe-tub, in conſequence of the air entangled with it, ſhould conſtantly be ſkimmed off in a careful manner, and be depoſited in the cream-veſſels.

As no general rule has yet been eſtabliſhed, whereby to determine either the quantity of rennet to be applied, or the proper

proper temperature of the milk at the period of application, it can only be ſtated, that each dairy-maid is obliged to exerciſe her own diſcretion, according to the exiſting circumſtances, in regulating her conduct in this reſpect. But although practice is the only means by which ſhe can acquire a proper knowledge of this branch of the buſineſs, yet the conſequences of proper or improper conduct are well known in every cheeſe-dairy. When the coagulation is accelerated or retarded beyond the proper time, which in making a 60 pound cheeſe is reckoned one hour and a half, either by giving too much or too little rennet, or by applying it when the milk is too hot or too cold, not only the quantity of the curd is diminiſhed, but the quality in either caſe materially affected. In the former caſe it is of a tough, gluey texture; in the latter, too tender.

After the colouring and rennet have been applied, the milk-tub is covered by a board or wooden cover, over which is laid a linen cloth; and having ſtood the uſual time, which is about an hour and half, in which it is frequently examined; and where the cream riſes to the ſurface, before the coming takes place, as is often the caſe, the whole is to be ſtirred together, ſo as to well blend the milk and cream again; and this repeated as often as neceſſary, till the coagulation is formed, which may ſometimes be haſtened by gentle ſtrokes on the ſides of the tub; or, where coolneſs is ſuſpected as the cauſe of its not coming properly, heat in ſome way or other may be applied for the purpoſe, and cold in the contrary circumſtances; and even when an additional quantity of rennet is required, it may likewiſe at this period be applied, that is, before the coagulation occurs; but when the dairy maid finds that the coagulation is completed, which is known by gently preſſing the ſurface of the milk with the back of the hand, or by leaving the ſkimming diſh inverted in the ſurface of the milk, where the whey will appear on its removal, ſhe ſets to work with her aſſiſtants to ſeparate the curd from the whey, an operation which is generally called breaking and gathering the curd.

Breaking and gathering the Curd.

Simple as this buſineſs may appear, and uniform as one would expect the method to be, there are few particulars, ſays Mr. Donaldſon, in the whole art of cheeſe-making, wherein ſo great a difference is obſervable in practice. In ſome dairies, the curd, when ſtiff, is at firſt broken or cut in various directions with a common caſe-knife, or cheeſe-knife made for the purpoſe, and uſed with a view of making the whey ſeparate eaſily, and without carrying off with it any richneſs from the curd. After theſe firſt inciſions, ſome time is allowed for the broken curd to ſubſide. The knife is then again uſed, and more freely than before; and while the dairy-maid ſtirs up the unbroken curd from the bottom with the ſkimming-diſh in one hand, ſhe cuts the larger pieces of curd with the knife, which ſhe holds in the other. This method, as well as that by the hand is continued until the whole of the curd is broken down and reduced in an uniform manner into ſmall particles. This buſineſs in general occupies about forty minutes, the curd being then left covered over with a cloth for about half an hour, in order to ſubſide. See CHEESE-KNIFE.

Having thus thoroughly broken the curd, and allowed ſome time for its ſubſiding, ſhe then begins to take off the whey with the ſkimming-diſh. In other dairies not leſs celebrated for good cheeſe, the ſkimming-diſh only is uſed in breaking the curd; this is particularly the caſe where the milk has been ſet cool together, and the curd is of courſe more tender, the edge of it being held perpendicular to the ſurface of the whey in the tub, being dipped gently into it an inch or two, and the whole curd in that way turned. The breaking is then performed in a gentle manner, moſtly by the hand, more time being allowed for the purpoſe.

And in order to facilitate the operation of ſeparating the whey from the curd, ſome of the whey that firſt riſes to the top is ſkimmed off, and being either heated or cooled, according to the ſtate of the weather, and the required conſiſtence of the curd, is again returned into the cheeſe-tub; and after remaining a little time, the whole is laded off in the uſual manner. All the whey that can be extracted without preſſure having been removed, and the cheeſe-tub being raiſed at one ſide, the curd is collected into a maſs, and at firſt preſſed with the back of the ſkimming diſh. When no more whey can be diſcharged by this means, others more violent are adopted; the curd is, in many caſes, cut with the cheeſe-knife, to give vent to the whey, and is then preſſed as hard as poſſible with the hands; in others, a conſiderable weight is frequently applied, by means of a board of a ſemi circular form contrived to fit one half of the cheſe tub's bottom in a looſe manner, being placed upon the curd; the parts which are forced out by the preſſure being again and again cut off, and replaced under the board, and the whey preſſed out, continually removed as it is formed. The whole maſs of the curd is now turned upſide down, put on the other ſide of the tub, then again preſſed, pared, and preſſed as in the former caſe. The board and weight being removed, the curd is cut into pieces eight or nine inches ſquare, which are piled upon each other, and then preſſed with the board and weight, the cutting and piling being repeated till no more whey drains off from it. The curd having been in a great meaſure ſeparated from the whey, it is put into two or three pans, or other veſſels, and the dairy-maid and her aſſiſtant break it with their hands as fine as poſſible; in the courſe of doing which, a proper quantity of ſalt (for the weight or meaſure is ſcarcely in any inſtance aſcertained) is ſcattered over the curd, and intimately mixed therewith. Sometimes the curd is divided into three portions, being broken down and ſalted ſeparately, the middle portion often conſiderably the moſt.

According to the method uſually practiſed in Glouceſterſhire, when the curd is broken to the requiſite fineneſs, it is again returned into the cheeſe-tub, where it is ſcalded, by pouring over the broken curd a pailful of hot-water, or of whey, or of whey and water mixed. After the ſcalding-water or whey is applied, the whole is briſkly ſtirred, and being allowed to ſtand for ſome time for the curd to ſettle at the bottom of the tub, the ſcalding materials are ſkimmed or poured off, and the curd being preſſed as before, ſo that no more whey can be extracted by ſuch means as were formerly uſed, it is put into the vat, and preſſed in the ordinary way.

Vating and preſſing the Cheeſe.

As ſoon as the curd has been properly broken down, rubbed, and ſalted, a cloth is ſpread over the cheeſe-vat, which in Scotland is called a *cheſſel*, and the broken curd being packed into it ſo as to be heaped up in a conical form above it, and covered up with the cloth, by being turned up at the corners, after being preſſed by the hand ſo as to adhere together, a board is laid over the vat, and a weight heavy in proportion to the quantity of curd, placed upon it, by which means the remaining whey is preſſed out. Where the cheeſes uſually made are of a large ſize, as in Cheſhire, the dairyman thruſts a number of iron ſkewers, through holes made in the ſides of the vat for the purpoſe, into the curd in various directions. Theſe being withdrawn, the openings made by them ſerve as ſo many drains for permitting the whey to run off. In ſome dairies they have recourſe to *thruſting* ſcrews, which

which are fixed to the floor above, the power of which can be regulated at pleaſure. In others a lever is uſed to preſs or thruſt the cheeſe, which is a long ſtrong pole, having one end faſtened in the wall, in a direction nearly parallel to the top of the cheeſe, on which a board is placed for the reception of the power of the lever, which is made uſe of at diſcretion. When the whey, in place of running freely, which it does at firſt, only falls in drops, the weight is removed, and the curd re-broken, and, being again put into the vat, is managed in the manner juſt deſcribed, and repeated while, by uſing ſuch means, a drop of whey can be extracted. The curd being now almoſt entirely freed from the whey, it is again placed in the vat, a clean cloth having been previouſly ſpread for the purpoſe of receiving and incloſing it. The curd now takes the form, at leaſt, of cheeſe; and the cover of the vat being on, it is placed in the cheeſe preſs. See CHEESE-PRESS.

It is extremely neceſſary that large dairies ſhould be well provided with vats of different ſizes, as where three or four cheeſes are made at each meal, a great number of vats become abſolutely in uſe, and where there are not at the ſame time a number empty, the operator is confined in his choice, and cannot proportion exactly the vats to the ſizes of the cheeſes, or rather the quantity of curd in the tub, and when a little overplus curd is preſerved from meal to meal, it often happens that a whole cheeſe is ſpoiled. The vats ſhould always be ſo choſen that the quantity of curd may neither over or under fill them, when the cheeſes are fully preſſed.

Before the cheeſe is put in the preſs, it is uſually turned in the vat, and rinſed with warm whey. The cloth now made uſe of being finer and longer than that formerly employed, and is ſo placed, that on one ſide it may be level with the edge of the vat, and on the other wrap over the whole ſurface of the cheeſe, and the edges put within the vat, thus perfectly encloſing the whole cheeſe in the cloth. In this ſtage of the proceſs the cheeſe is ſtill higher than the edge of the vat, but to preſerve it in due form, recourſe is had to a tin-binder, or hoop, about three inches broad, which is put round the cheeſe, on the outſide of the cloth, and the lower edge of the binder preſſed down with the vat, ſo low as that the upper edge of it may be level with the ſurface of the cheeſe. In this ſtate a ſmooth board being placed over it, the preſs is gently let down upon it. There are moſtly preſſes of different weights; ſome dairies putting them under the preſſure of the heavieſt, and others of the lighteſt, the firſt. And occaſionally cheeſe fillets are made uſe of inſtead of the tin-binders, for which a coarſe ſort of broad ſtrong tape is uſed, one end of which is thruſt down with a thin wooden knife between the cheeſe-cloth and vat, and then drawn tightly ſeveral times round the cheeſe, faſtening it with ſtrong pins. As ſoon as the vat with the cheeſe is placed in the preſs, and the weight applied, ſkewers are again thruſt in through the holes in the ſide of the vat and binder, left for the purpoſe: this is done repeatedly during the firſt day the vat is in the preſs. It is performed by ſkewers of ſtrong iron wire, eighteen or twenty inches in length, ſharp at the points, and turned with a bow at the other end. The operation of ſkewering commonly continues till the morning after the cheeſe has been put in the preſs, and the oftener the cheeſe is ſhifted in that time the better, it being generally taken out, and turned in about half an hour, the angles being pared, where thoſe of the vats are not rounded off. There is, however, much difference in this reſpect in different inſtances, but the interval from the time the vat is firſt placed in the preſs till it is again taken out, does not, in ordinary caſes, at moſt exceed two or three hours. When taken out, the naked cheeſe is put into a veſſel with hot whey, or warm water, with the view of hardening its coat or ſkin, and preventing bliſters, where it ſtands for an hour or two; it is then taken out, wiped dry, and after having remained ſome time to cool, it is covered with a clean dry cloth, and the vat being wiped dry, and the cheeſe replaced, it is again put into the preſs. In the evening, ſuppoſing the cheeſe to have been made in the morning, which is the uſual time, it is again taken out of the vat, and another dry cloth being applied, it is turned and replaced; what was formerly the upper becoming now the under-ſide. At this and the former turning the upper ſurface is ſometimes pricked, all over, an inch or two deep, to prevent bliſtering. In this manner it is taken out, wrapped in clean cloths, and returned into the vat twice a day, for two days, when it is finally removed. In the two laſt turnings finer cloths are made uſe of, that no marks or impreſſions may be left on the cheeſe.

Theſe are the methods moſtly followed in the principal dairy diſtricts; but other modes are in practice in other places, as well as in many inſtances in theſe. It is often the cuſtom to bare-vat the cheeſes at the latter end of the preſſing.

Salting of the Cheeſe.

The ſalting of the cheeſe is the next part of the management. The cheeſe, on being for the laſt time removed from the preſs, and taken out of the vat, is carried to the ſalting-houſe, and placed on a fine cloth in the vat, in a ſalting tunnel or tub filled to a conſiderable depth with brine, in which it ſtands for ſeveral days, being regularly turned once at leaſt every day. But a method now more generally uſed is, to cover the upper ſurface of the cheeſe wholly with ſalt, repeating the application at every turning, for about three days, and changing the cloths twice in the time. But in the firſt mode, the vat is then removed from the brine-tub; and the cheeſe being taken out, is placed on the ſalting bench, where it ſtands for eight or ten days, ſalt being carefully rubbed over the whole every day, during that period. This is likewiſe the caſe in the latter method. Where the cheeſe is of a large ſize, it is commonly ſurrounded with a wooden hoop, or fillet of cloth to prevent renting. After it is ſuppoſed to be ſufficiently ſalted, it is waſhed in warm water or whey, and, when well dried with a cloth, is placed on what is called the drying bench, where it remains a like period before it is removed to the keeping houſe or chamber. In other dairies, the new cheeſes are not put in brine, but kept in the vats on the ſalting benches; and after being rubbed with ſalt, and turned in the vats daily for a week or ten days, the vats are removed, and the cheeſes managed in the manner above-mentioned. In ſeveral other dairies, again, the cheeſes are ſalted while the operation of preſſing is performing. At every time they are taken out of the preſs, for the purpoſe of being turned in the vats, they are well rubbed with ſalt, which for ſmall thin cheeſes, ſuch as are commonly made in Wiltſhire and Glouceſterſhire, is found to be ſufficient; and therefore when taken for the laſt time from the preſs, in place of any more ſalt being applied, they are ſet at once upon the drying benches.

The practice of immerging new made cheeſes in brine is now principally adopted where they are of ſo large a ſize that rubbing ſalt on the outſide would not be ſufficient for anſwering the intended purpoſe of preſerving them, &c.

It is found that in Cheſhire twenty eight pounds or half a buſhel of ſalt in the week, is ſufficient on the average through the ſummer for dairies where ſixty pounds cheeſes are made, including the domeſtic conſumption in families of moderate ſizes. And that the greateſt quantity of ſalt uſed for one ſixty pounds cheeſe is about three pounds; but what the actual quantity is which is retained in the cheeſe, has not been aſcertained.

Neceſſary Management in the Cheeſe Room.

The laſt part of the buſineſs of cheeſe-making is the management in the cheeſe-room. When the cheeſes are properly ſalted, and have acquired a competent degree of dryneſs, they are carried from the ſalting place to the cheeſe-room, or ſtore-houſe; where, after being ſmeared with freſh butter, or ſweet whey butter, they are laid on the floor, or on ſhelves erected for the purpoſe. For the firſt ten days, or a fortnight after they are placed in the ſtore-room, they are pretty ſmartly rubbed all over every day, and the ſmearing with butter repeated; however afterwards, a round ſpace, of four or five inches diameter on each ſide, in the middle is left unrubbed; but although after that period it may be only neceſſary to rub them two or three times in the courſe of the week, they ſhould be daily turned, as long as they are kept; the uſual practice is to rub them three times in the week in ſummer, and twice in the winter ſeaſon. And the ſcraping of the rind ſhould be rendered unneceſſary by frequent cleanings. Where the room is warm the coat will eaſily be prevented from riſing.

In Cheſhire the cheeſe-rooms are moſtly placed over the cow-houſes, in order to derive that moderate and neceſſary degree of temperature, which is ſuppoſed *eſſential* to the ripening of cheeſe, from the cattle below. In ſome caſes the floors are rubbed with different green vegetables, as bean-tops, &c., in others dry ſubſtances are uſed; but in Cheſhire, dried coarſe graſs or ruſhes, termed *ſniddle*, is uſed as a litter for the floors, and ſometimes wheat ſtraw, but which is objectionable, from its knots making impreſſions on the cheeſes. And Rouen hay is adviſed as a proper material for the purpoſe.

It may be proper, before we come to introduce ſome miſcellaneous remarks on a few circumſtances in reſpect to cheeſe, to deſcribe the methods of making ſome other kinds of cheeſe.

Method of making Parmeſan Cheeſe.

The mode which is uſually adopted, according to Mr. Price, as ſtated on the authority of ſignior Vitabni, is to put, at ten o'clock in the morning, five *brints* and a half of milk, each brint containing about forty-eight quarts, into a large copper, which turns on a crane, over a ſlow wood-fire, made about two feet below the ſurface of the ground; the milk is ſtirred from time to time; and about eleven o'clock, when juſt lukewarm, or conſiderably under a blood-heat, a ball of rennet, as big as a large walnut, is ſqueezed through a cloth into the milk, which is kept ſtirring. By the help of the crane, the copper is turned from over the fire and let ſtand till a few minutes paſt twelve; at which time the rennet has ſufficiently operated. It is now ſtirred up and left to ſtand a ſhort time. Part of the whey is then taken out, and the copper again turned over a fire ſufficiently briſk to give a ſtrongiſh heat, but below that of boiling. A quarter of an ounce of ſaffron is now put in to give it a little colour, and it is well ſtirred from time to time. The dairy-man frequently feels the curd. When the ſmall, and, as it were, the granulated parts, feel rather firm, which is in about an hour and an half, the copper is taken from the fire, and the curd left to fall to the bottom. Part of the whey is taken out, and the curd brought up in a coarſe cloth hanging together in a tough ſtate. It is then put into a hoop, and about half a hundred weight laid upon it for about an hour; the cloth being then taken off, and the cheeſe placed on a ſhelf in the ſame hoop. At the end of two or from that to three days, it is ſprinkled all over with ſalt; the ſame is repeated every ſecond day, for about forty or forty-five days, after which no further attention is required. While ſalting they generally place two cheeſes one upon another in which ſtate they are ſaid to take the ſalt better than ſingly.

Method of making Stilton Cheeſe.

The proceſs for making this highly valuable ſort of cheeſe is thus ſtated in the Report on Agriculture for Leiceſterſhire: the night's cream is put into the morning's new milk, with the rennet, when the curd is properly come, it is not broken, as is the caſe in the making of other cheeſe, but is taken out with the ſoil-diſh altogether, and placed in a ſieve to drain gradually; and as it drains kept gradually preſſed, till it becomes firm and dry; being then placed in a wooden hoop, and afterwards kept dry on boards, frequently turned, having cloth binders paſſed round it, which are tightened occaſionally as found neceſſary.

Method of making Green Cheeſe.

In the making of a cheeſe of this ſort of about ten or twelve pounds weight, an infuſion made by ſteeping about two handfuls of ſage, and one of marigold leaves, with a little parſley, after being bruiſed, one night in a proper quantity of milk. In the morning the greened milk is ſtrained off, and mixed with about one-third of the whole quantity to be run. The green and the white milks are then *run* ſeparately, keeping the two curds diſtinct, until they are ready for vatting. The mixing of them depends on the fancy of the maker. In ſome caſes the two are connected together, blending them in an even and intimate manner; in others, the green curd is broken down into irregular fragments, or cut out in irregular figures by means of proper tins. In the operation of vatting, the fragments or figures are placed on the outſides. The bottom of the vat is firſt ſet with them, crumbling the white or yellow curd among them. As the vat fills, others are placed at the edges, and the remainder buried fluſh with the top. In the management afterwards, the ſame plan is purſued as thoſe which have been deſcribed for common cheeſe.

Miſcellaneous Circumſtances in the Management of Cheeſe.

The *cracks*, which ſo frequently take place in cheeſe, have been aſcribed to various cauſes; as, lime being employed as a manure, expoſure to a current of air after being taken out of the preſs, eſpecially before they have ſweated in the cheeſe-room. Some of theſe cauſes are, however, extremely doubtful.

The *rankneſs* and *pungency* of cheeſe are commonly attributed to the impurity of the ſteep, to neglect in waſhing out and ſcalding the ſteep cup daily, and to the want of ſalt: but ſome ſuppoſe it, with greater reaſon, to be owing to the imperfect ſeparation of the curds and whey. Heaving and running out at the ſides, as well as ſpungy, eyey, and whey ſpringy cheeſe, are all aſcribed to the ſame cauſe.

The *heaving* of cheeſe is moſt generally ſuppoſed to depend upon the ſweating or fermentation not being perfectly performed. Some, however, ſuppoſe it to depend on the rankneſs of the paſtures; the improper temperature of the cheeſe-room, and various other cauſes, as may be ſeen in the Report on Agriculture for Glouceſterſhire.

The *bliſters* of cheeſe are likewiſe ſuppoſed to proceed from the ſame cauſes. The uſual remedy is opening them, and pouring hot water into the inciſions; then preſſing down the outer rind, putting a little ſalt upon it, with a piece of ſlate and a half pound weight.

The *running out at the ſides*, is ſuppoſed to ariſe from the ſame cauſes as heaving; or the want of due preſſing: the

uſual remedy is that of binding it tightly round with a cheeſe fillet.

The uſual remedies of *ſpongy*, *eyey*, and *whey ſpringy* cheeſe are careful breaking, good thruſting, frequent ſkewering, and a powerful application of the preſs.

In caſes where milk is converted into cheeſe, the produce which is afforded by the cows is ſtated in very different ways, in different diſtricts where this ſort of practice is purſued. In ſome 2½ *cwt.* from each cow, whether good or bad milkers, is ſuppoſed a very good average annual return. In others it is ſtated to be three hundred weight, and from that to three and an half, and even four. Mr. Rudge, indeed, ſtates it to riſe in the Glouceſterſhire dairies ſo high as from three hundred and a half to four hundred and a half weight in the ſeaſon.

On the general ſuppoſition of farmers, that a cow requires the produce of from two and a half to three acres and a half of land for her ſupport the year round, the average quantity of cheeſe by the acre may be ſtated as ſomething more than one hundred and eighteen pounds. But all theſe ſorts of ſtatements are very uncertain, from the great differences of circumſtances.

The following ſtatement is given by Mr. Rudge, as the profit on a dairy of twenty cows in Glouceſterſhire:

Debtor.	£.	s.	d.
Rent of forty acres of land for paſture -	60	0	0
—— of twenty acres for hay -	30	0	0
Making hay at 12*s.* per acre - -	12	0	0
Carrying and ricking - -	3	0	0
Tythe at 2*s.* 6*d.* per pound - -	11	5	0
Poor and highway rates, at 3*s.* - -	13	10	0
Two women to milk, at 3*s.* per week -	7	16	0
Dairy-woman, at 4*s.* 6*d.* per week -	11	14	0
Labourer in winter to fodder - -	4	10	0
Wear and tear of dairy utenſils - -	3	0	0
Salt - - - -	3	0	0
Annotto, at 7*s.* per *lb.* - -	1	15	0
Intereſt of money laid out in ſtock and implements (reckoning each cow at 20*l.*), and chance of loſs - -	40	0	0
Profit - - - -	136	10	0
	338	0	0

Creditor.	£.	s.	d.
Cheeſe, 4 tons, at 4 *cwt.* each cow, and 3*l.* 3*s.* per *cwt.* -	252	0	0
Value of Whey - -	40	0	0
Paſture for colts and ſheep -	10	0	0
Profit of calves - -	21	0	0
—— of butter - -	15	0	0
	338	0	0

It is however here ſuggeſted, that the dairy farmer is probably charged with expences higher than he really incurs, from the work being differently performed, and the ſervants being often engaged in other ſorts of work; and likewiſe from the whey being charged at the ſelling price, and not at that of its value as a food for ſwine.

Much of the profit of well-managed dairies may ariſe from the hogs. It is ſtated by Mr. Rudge, that from eight to ten hogs, of nine or ten ſcore each, are uſually kept to twenty cows. But where hogs are not kept, the whey is valued and ſold at two pounds per annum. See SWINE.

DAIS, in *Botany*, (Δαις, a ſolemn feaſt; perhaps from the profuſion and beauty of the flowers; which profeſſor David Van Royen, who founded and named this genus, held in great eſtimation, and conſidered as the pride of his garden at Leyden, in 1786.) Linn. Gen. 215. Schreb. 292. Willd. Sp. Pl. v. 2. 579. Juſſ. 77. Gært. t. 39. Claſs and order, *decandria monogynia*. Nat. Ord. *Vepreculæ*, Linn. *Thymelææ*, Juſſ.

Gen. Ch. *Cal.* Involucrum of four leaves, containing many ſeſſile flowers; its leaves ſcarioſe, erect. Perianth none. *Cor.* of one petal; funnel-ſhaped, longer than the involucrum; tube thread-ſhaped, rude; border in five (ſometimes but four) deep, lanceolate, obtuſe ſegments. *Stam.* Filaments ten (ſometimes but eight), inſerted into the tube, ſhorter than the limb, alternately longer and ſhorter; anthers ſimple. *Piſt.* Germen oblong-ovate, ſuperior, cloſely inveſted by the baſe of the petal; ſtyle thread-ſhaped, as long as the tube; ſtigma globoſe, curved upward. *Peric.* Berry ovate, of one cell, leathery. Seed ſolitary.

Eſſ. Ch. Involucrum of four leaves. Corolla in four or five ſegments. Berry dry, with one ſeed.

Dais *cotinifolia*, Curt. Mag. t. 147.; the original and moſt intereſting ſpecies, is a ſhrub, ſix or eight feet high, much branched. *Leaves* deciduous, oppoſite, on ſhortiſh ſtalks, obovate, entire, ſmooth, opaque, pale, and ſomewhat glaucous. *Flowers* terminal, of a delicate lilac hue, externally ſilky, forming elegant tufts at the end of each branch. It is a native of the Cape of Good Hope, from whence the Dutch received it long before it was known in England. It thrives with us in the ground of a conſervatory, better than in a pot, and is propagated only by ſeeds obtained from abroad. D. *octandra* (D. *laurifolia*, Jacq. Ic. Rar. t. 77), grows in the Eaſt Indies, and has larger leaves, of a deeper green, and ſmooth flowers, whoſe ſegments are occaſionally five or four, with ten or eight ſtamens. A third ſpecies, D. *diſperma*, found by Forſter in Tongatabu, varies likewiſe in the number of the parts of its flowers.

DAIS, in *Gardening*, comprehends a plant of the ſhrubby, deciduous, ornamental kind; the D. *cotinifolia*, cotinus-leaved dais; in which the leaves are oppoſite, the flowers in a bunch aggregate, terminating and pubeſcent, and the fruit a ſmall nut of an ovate-acuminate form. It is a native of the Cape.

Method of Culture.—This is a plant which is capable of being raiſed by ſowing the ſeed, which may be had from Holland, in pots of light earth, in the ſpring ſeaſon, and plunging them in a good hot-bed: as ſoon as the plants have acquired a ſufficient growth, they muſt be removed into ſeparate pots of a proper ſize, and be placed under the protection of the green-houſe. It is likewiſe a plant which occaſionally ſucceeds by layers and cuttings, if made from the young ſhoots. The great difficulty of raiſing it, however, renders it a ſcarce plant in our green-houſes.

DAISY, in *Botany*. See BELLIS *perennis*; alſo CHRYSANTHEMUM, ASTER, and GLOBULARIA. The name is derived from day and eye, alluding to the eye-like form of the flower, and its expanſion in the day, and in bright weather only, when it preſents its front to the ſun, following his courſe till the afternoon, when the flower cloſes, but opens again for many ſucceſſive mornings.

DAIX, in *Ancient Geography*, a river of Scythia, on this ſide of mount Imaus. It ſprang from mount Noruſſus, and diſcharged itſelf into the Jaxartes.

DAKER HEN, in *Ornithology*, one of the ſynonyms of the rail. See RALLUS *crex*.

DAKIR, in our ſtatutes, is uſed for the twentieth part of a laſt of hides.

According to the ſtatute of 51 Hen. III. "De compoſitione ponderum & menſurarum," a laſt of hides conſiſts of twenty dakirs, and every dakir of ten hides. But by 1 Jac. cap.

cap. 33. one laſt of hides or ſkins is twelve dozen. See Dicker.

DAL, or Dahl, *Dal elbe, Dal elfwe, Dal älf, (the river of the valley)*, in *Geography*, the largeſt and fineſt river of Sweden, riſes in the mountains which ſeparate Sweden from Norway, and conſiſts originally of two ſtreams, which, after having watered the whole province of Dalecarlia, unite in the pariſh of Gagneſs. That branch which waters the eaſtern part of Dalecarlia is called the Oeſter Dal Elfwe, and that which runs through the weſtern part Weſter Dal Elfwe.

After a courſe of about 260 miles, the Dal falls into the Gulph of Bothnia, near Elfkarleby, about ten miles to the eaſt of Gefle. It flows in a broad and tranquil ſtream, until it reaches a ridge of rocks, and a high iſland a quarter of a mile in circumference, where the whole river forms a cataract ſcarcely inferior to that of the Rhine at Schafhauſen. The iſland divides the cataract into two principal falls, of which the eaſtern is the fineſt. The breadth of the river is about a quarter of a mile, and the perpendicular height of the fall between thirty and forty feet. Coxe's Travels, vol. v.

Dal, the ablative caſe of the Italian article; as *dal* or *del ſig. Paeſiello*, by ſignor Paeſiello; *Dal l'Inferno di Dante*, from Dante's Inferno.

DALA, in *Geography*, a river of Switzerland, which from the canton of Berne flows into the republic of the Vallais, paſſing by the baths of Leuk, and running afterwards through an abyſs ſo deep and ſo obſcure, that, notwithſtanding the violence and noiſe of its current, the river is neither ſeen nor heard. Coxe's Switzerland.

Dala *Syſſel*, or *Dale Syſſel*, commonly called *Breyda fiardar daler*, from the bay of Breydafiardur, is, according to Buſching, the moſt delightful, or rather the only pleaſant, tract of country in Iceland. The mountains run in two parallel lines, and the valleys between are watered by a number of little brooks and rivulets.

DALABORG, or Dalebourg, a ſmall and formerly fortified town of Sweden, in the ſouthern part of the province of Dalecarlia, on the weſt ſide of the lake Wener, 50 miles N. of Gothenburg.

DALAI. See Coulon.

DALATIS, in *Ancient Geography*, a country of Aſia, in Cilicia, mentioned by Ptolemy.

DALBERGIA, in *Botany*, (named by Linnæus in honour of two brothers of the name of Dalberg, to whom he was indebted for many Surinam plants.) Linn. Suppl. 53. Schreb. 483. Willd. Sp. Pl. v. 3. 900. Juſſ. 362. (Ecaſtaphyllum, Browne Jam. 299. t. 32. f. 1.) Claſs and order, *diadelphia decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* of one leaf, bell-ſhaped, with five bluntiſh teeth. *Cor.* papilionaceous; ſtandard large, aſcending, ovate inclining to heart-ſhaped, notched, with a linear claw; wings oblong, ſtraight, obtuſe, with a recurved tooth at their upper edges; keel ſcarcely ſhorter than the wings, ſtraight, obtuſe, cloven at the baſe. *Stam.* Filaments two, each in four or five ſegments, in ſome inſtances accompanied by a third ſmall ſimple filament; anthers eight or nine, ſcarcely more, globoſe, two-lobed. *Piſt.* Germen ſtalked, compreſſed, oblong, ſtraight, ſmooth; ſtyle aſcending or reflexed, deciduous; ſtigma capitate. *Peric.* Legume ſtalked, thin, flat, cartilaginous, ovate or oblong, cloſe, not burſting, containing one or more ſeeds. *Seeds* compreſſed, ſomewhat kidney-ſhaped.

Eſſ. Ch. Stamens in two equal ſets. Legume ſtalked, coriaceous, compreſſed, not burſting.

Two ſpecies only of this genus are deſcribed. D. *lanceolaria*, Linn. Suppl. 316. (Noel-valli, Rheede Hort. Mal. v. 6. 39. t. 22.) A native of Malabar and Ceylon, from whence Konig ſent it to Linnæus. It is a tree with long, wand-like branches, clothed with ſoft whitiſh hairs. *Leaves* alternate, pinnate, with numerous, alternate, elliptical, waved, entire leaflets, hairy above. Flowers in axillary hairy bunches. Legume lanceolate, acute, about two inches long, with one ſeed, rarely two, imbedded in its middle part.

D. *monetaria*, Linn. Suppl. 317. is found in wet ſituations in Surinam. The leaves are ternate. Legume orbicular, deciduous, harder than in the former. The wood of this tree or ſhrub is red, and yields a reſin reſembling what is called Dragon's-blood.

DALBY, in *Geography*, a ſmall town of Sweden, in the province of Schonen, or Scania, where Suen king of Denmark built, in the year 1065, a convent, in which two kings are buried: but in 1512 this convent was ſequeſtered to the crown by Chriſtian III. of Denmark, to whom Scania was then ſubject.

DALDÆ, in *Ancient Geography*, an epiſcopal town of Aſia Minor, in Lydia.

DALE, Samuel, M.D.; in *Biography*, but who applied himſelf more to the ſtudy of botany than to the practice of medicine, was born in the year 1659. He firſt ſettled as an apothecary, at Braintree, in Eſſex; but in 1730 he became a licentiate of the college of phyſicians, in London, in which capacity he practiſed medicine at Bocking, where he continued to reſide to the time of his death, which happened in 1739. He was alſo elected a fellow of the royal ſociety. In 1693 he publiſhed "Pharmacologia ſeu manuductio ad materiem medicam," 8vo. London, which has paſſed through many editions. The author lived long enough to publiſh an edition of his work in 4to, in 1737, much enlarged and improved, which has alſo been frequently reprinted. In this he has diſpoſed of the plants in the manner adopted by Ray. In the firſt part of the work the author deſcribes and gives an account of the properties and manner of uſing the plants moſt eſteemed in medicine. In the latter part, in a ſupplement, plants leſs known and uſed, with ſome that had been very lately diſcovered in America, and other foreign countries, are deſcribed. He alſo publiſhed in 1732, in 4to, "Silas Taylor's Hiſtory and Antiquities of Harwich and Dover Court," to which he made conſiderable additions. In this he diſplays an accurate knowledge in the ſeveral branches of natural hiſtory, giving an exact account of the figured foſſils of the cliff, and an intelligent ſynopſis of the animals and vegetables of the neighbouring ſea and coaſt. Gen. Biog.

Dale, in *Geography*, a river of Ireland, flowing from a ſmall lake of the ſame name in the county of Donegal, which runs into the Foyle, a little below Lifford. This river is navigable for boats from the Foyle to the village of Ballindraite.

DALEA, in *Botany*, (after Samuel Dale, a botaniſt of the time of Ray, author of the Pharmacologia.) Linn. Hort. Cliff. 363. Juſſ. 355. Willd. Sp. Pl. v. 3. 1336. (Pſoralea, Linn. Gen. 386. Schreb. 508.) Claſs and order, *diadelphia decandria*, ſect. 1. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Gen. Ch. *Cal.* of one leaf, dotted with prominent glands, five-cleft; ſegments awl-ſhaped, permanent. *Cor.* Papilionaceous; ſtandard roundiſh, erect, notched; wings ſmall, obtuſe, united to the filaments, as is alſo the keel, which conſiſts of two obtuſe petals. *Stam.* Filaments five or ten, united into one ſet; anthers roundiſh. *Piſt.* Germen oblong; ſtyle awl-ſhaped, as long as the ſtamens; ſtigma

ſimple. *Peric.* Legume encloſed in the calyx, of one cell. *Seed* ſolitary, kidney-ſhaped.

Eſſ. Ch. Wings and keel united to the ſtamens, which are monadelphous. Legume of one ſeed.

Linnæus, after having eſtabliſhed this genus in his earlier works, referred it ſubſequently to *Pſoralea*, but Juſſieu and Willdenow have juſtly reſtored it. The monadelphous filaments, united to the wings and keel, afford a ſufficient character. Juſſieu thought all the ſpecies were pentandrous; but Willdenow finds only five that are ſo, nine being decandrous, in all fourteen. His *Dalea cliffortiana*, Linn. Hort. Cliff. t. 22. (Pſoralea Dalea, Linn. Sp. Pl. 1076), is a rare South-American ſpecies. Several are found in North America, of which Michaux has made his genus *Petaloſtemum;* others in Mexico, figured in Cavanilles' *Icones*. The leaves of all are pinnate, with a terminal leaflet, and glandular beneath. Flowers for the moſt part of a dull blueiſh hue, in denſe hairy ſpikes. Habit more or leſs ſhrubby.

DALECARLIA, Daland or Thalland, in Latin *Dalia*, and in Swediſh *Dal* or *Dalarna*, in *Geography*, a province of Sweden, in the weſtern part of Gothland, between the Wener lake and the government of Gothenburg, derives its name from the great number of vallies which it contains. It is ten Swediſh miles long, and five and a half broad.

This country is richly diverſified with an alternate ſucceſſion of foreſts, rocks, hills and dales, uplands and plains, paſtures and arable land, lakes and rivers; and the beauty of the landſcapes is particularly heightened by the river Dal. Sillian, its principal lake, is ſeven Swediſh miles in length, but not above a quarter of a mile in breadth.

Dalecarlia is ſubdivided into the north and ſouth part. The former is rocky and mountainous; its chief place is Amal, and its higheſt mountain the Borekne. The ſouth part is a champain country, and has no town but Dalaborg. Towards the ſouth it produces corn; but its chief articles are cattle, fiſh, butter, and cheeſe. It has a number of mines.

The inhabitants, who are called Dalecarlians, are famous in hiſtory for their integrity and firm attachment to their king and country, and for their courage and bravery. They firſt ſupported Guſtavus Vaſa, and enabled him to attempt thoſe efforts which ended in the expulſion of Chriſtian the Second, and in the eſtabliſhment of the houſe of Vaſa on the Swediſh throne. Guſtavus III., who prided himſelf on his deſcent from Guſtavus Vaſa, ordered a wet nurſe for the preſent king of Sweden, his ſon, to be choſen among the women of Dalecarlia; and in the dangers which threatened Sweden, in 1788, the Dalecarlians were foremoſt in offering their ſervices for the defence of their country. The Dalecarlians ſtill retain the manner of living, dreſs, and cuſtoms, of the ancient Swedes.

Dalecarlia may be called the claſſical ground of Sweden, being full of memorials which indicate the veneration of the natives for the memory of Guſtavus Vaſa.

The four principal villages of Dalecarlia are Leckſand, Mora, Rättwik and Tuna. Each of theſe four pariſhes has from 7 to 11,000 inhabitants, and the vicarage of any of theſe, particularly of Leckſand, is more deſirable than many a Swediſh biſhopric in point of revenue.

In the midſt of the valley irrigated by the Dal, is a rock called *Buller Klac*, ſcarcely forty feet high, from the ſummit of which the naked eye diſcovers 35 villages, crowded with an immenſe population.

The language of the Dalecarlians differs ſomewhat from the Swediſh, and it has been aſſerted that it is a kin to the Icelandic. Profeſſor Enbergius ſays: "Dalica et Iſlandica per omnia adeo ſunt ſimiles, ut, quando Iſlandica accentu Dalico legitur, omnes Dalecarlicam eſſe judicent; id quod experimento certior factus." Ihre maintains that it was proved at Upſal in 1692, when divine ſervice was read to the Dalecarlians aſſembled there, in the Icelandic language. Some learned Engliſhmen are of opinion, that the Dalecarlian language is a dialect of the Celtic, like the language of Lower Britanny, Wales, and Ireland; and biſhop Ruden aſſures us, that a Swediſh ambaſſador brought with him to England a Dalecarlian boy, who could converſe with the Highlanders. There is indeed ſome ſimilarity between the Dalecarlian and the Scotch Highland dialect. (Promenade d'un François en Suede par de la Tocnaye, 1801. Coxe's Travels, vol. v.)

On the breaking out of the war, which has lately been declared by Ruſſia and Denmark againſt Sweden, the Dalecarlians have once more diſtinguiſhed themſelves by the moſt ardent attachment to their king and country. The regiment of Dalecarlia formed the van-guard of the army under general Armfeldt, deſtined againſt Norway, and in the latter end of March, 1808, penetrated fifty Engliſh miles into the enemy's country without meeting with any obſtacle.

DALECHAMP, James, in *Biography*, a learned French phyſician and indefatigable botaniſt, was born at Caen in 1513, ſtudied medicine and botany at Montpelier, was admitted doctor in medicine in 1547, and died at Lyons, where he had long practiſed phyſic, in 1588. He publiſhed ſeveral elaborate tranſlations, particularly of the 15 books of Athenæus into Latin, in 1552, in 2 vols. folio, illuſtrated with notes and figures; and ſome of the works of Galen and Paul Egineta into French. In 1556 he publiſhed a tranſlation of "Cœlius Aurelianus de Morbis acutis;" and in 1569, "Chirurgie Francoiſe, avec pluſieurs figures d'inſtrumens," 8vo., which has been ſeveral times reprinted. He principally followed the practice of Parée, from whoſe work he borrowed the figures of the inſtruments; but he has added a tranſlation into French of the ſeventh book of Paræus, with annotations, and ſome curious caſes occurring in his own practice. He was alſo the editor of an edition of Pliny with notes, publiſhed in 1587. His firſt work, according to Haller, was an 8vo. edition of Ruellius's Commentary on Dioſcorides, which appeared at Lyons in 1552, enriched by Dalechamp with 30 ſmall figures of plants, at that time but little known. His principal performance was an univerſal hiſtory of plants, in Latin, with above two thouſand five hundred wooden cuts, beſides repetitions, publiſhed after his death in 2 folio volumes. The publiſher, William Rouillé, ſeems to take upon himſelf the chief credit of collecting and arranging the materials of this great work, though he allows that Dalechamp laid its firſt foundations. Haller ſays, the latter was engaged in it for 30 years; his aim being to collect together all the botanical knowledge of his predeceſſors, and enrich it with his own diſcoveries. He employed John Bauhin, then a young man, and reſident at Lyons, to aſſiſt him; but Bauhin being obliged, on account of his religion, to leave France for Switzerland, like many other good and great men of that and the following century, the work in queſtion was undertaken by Des Moulins, and ſoon afterwards Dalechamp died. It is often quoted by the title of "Hiſtoria Lugdunenſis," and hence the merits of its original projector are overlooked, as well as the faults ariſing from its mode of compilation, which are in many inſtances ſo great as to render it uſeleſs. The ſame figure is occaſionally repeated for very different plants, an accident too common in books with wooden cuts; and the letter-preſs

ter-preſs is an aſſemblage of learning, criticiſm, and conjecture. which adepts only can turn to any certain profit. Many of the figures, however, are original and good, eſpecially among the graſſes, and ſome of the umbelliferæ. The author had a ſingular fancy of enriching, or rather encumbering his cuts with figures of inſects, which have no reference to the plants, and do not exactly reſemble any living thing. He ſeems to have been inſpired with the ſame taſte as a certain countryman of his, who ſays "Statues are the ſoul of a garden," and to whom, therefore, Eden itſelf, without ſquinting gods and goddeſſes, would have been dull and inſipid. Sometimes Dalechamp gives us ſeparate bloſſoms, fruits, or leaves; but they ſeem intended merely for decoration, and never teach any thing more than may be ſeen in the principal figure. How different from the cuts executed under the direction of Conrad Geſner! Throughout the work there are ſcarcely any traces of methodical arangement, much leſs of diſcriminating or aſſociating plants by their flowers or fruits. The ſtyle, indeed, is altogether deſultory. A French tranſlation was publiſhed in 1615, and again in 1653. Haller's Bibl. Bot. Nouv. Dict. Hiſtorique. Dalech. Hiſt. Pl. S.

DALECHAMPIA, in *Botany*, (named by Plumier after Dalechamp,, the French botaniſt.) Linn. Gen. 501. Schreb. 653. Willd. Sp. Pl. v. 4. 515. Juſſ. 392. Plum. Gen. t. 38. Claſs and order, *monoecia monadelphia*. Nat. Ord. *Tricoccæ*, Linn. *Euphorbiæ*, Juſſ.

Gen. Ch. Barren flowers ſeveral, enfolded by a pair of bracteas. *Cal.* Involucrum common, in 4 deep ſegments, which are erect, obtuſe, one of them, under the nectary, twice as large as the reſt; Perianth of 6 ovate reflexed leaves. *Cor.* Petals none; nectary broad, of numerous, obovate, flat leaves, in ſeveral rows. *Stam.* Filaments numerous, united into a tube as long as the calyx; anthers roundiſh, with four furrows.

Fertile flowers three, between the ſame bracteas. *Cal.* Involucrum common, of three leaves, which are upright, roundiſh, permanent, the outermoſt thrice broader than the reſt; perianth of 10 lanceolate, ſerrated, cloſed, permanent leaves. *Cor.* none. *Piſt.* Germen roundiſh, with 3 furrows, ſhorter than the calyx; ſtyle thread-ſhaped, very long, bent towards the barren flowers; ſtigma ſomewhat peltate. *Peric.* Capſule three-lobed, roundiſh, of 3 cells and 3 valves. *Seeds* ſolitary, globular. Jacq.

Eſſ. Ch. Barren flowers, Involucrum in 4 deep ſegments; Perianth of ſix leaves. Cor. none. Fertile, Involucrum of 3 leaves; Perianth of 10. Cor. none. Capſ. three-lobed.

D. *ſcandens*, the original ſpecies, Jacq. Amer. 252. t. 160, Plum. Amer. t. 101, a native of Martinico and Hiſpaniola, is chiefly known by the deſcriptions and figures of Jacquin and Plumier. It has a rough climbing ſtem, with tendrils; three-lobed, ſerrated, hairy leaves; and axillary green flowers on long ſtalks. The bracteas are large, deeply three-cleft, ſerrated, encloſing the flowers and ſeeds. D. *colorata*, found by Mutis in New Granada, has entire leaves and purpliſh bracteas. La Marck, in his Encyclopedie, deſcribed nine more ſpecies, eight of them from South America, one from China. None of theſe plants are at preſent known in the gardens of Europe. Their flowers are deſtitute of beauty.

DALEHR, in *Geography*, a fortreſs of Sweden, built on a rocky iſland, with a garriſon to guard the entrance and receive the duties of veſſels going to Stockholm.

DALEM, a town of Germany, in the circle of Weſtphalia, and biſhopric of Paderborn; ſeven miles E. of Buren.

Dalem, ſee Dalhem.

D'ALEMBERT, in *Biography*, ſee Alembert. This eminent mathematician and philoſopher would certainly merit a diſtinct article among muſical writers, for the clear and geometric arrangement and explanation of the diffuſed and obſcure theoretical writings of Rameau, if, in the article *Baſſe Fondamentale*, we had not already incidentally examined his muſical opinions, before and after his controverſy with the celebrated French opera compoſer and writer on the ſubject of muſic, in the two editions of his "Elements of Muſic, according to the Principles of Rameau."

The ſyſtem of Rameau, founded on the *Baſſe fondamentale*, was rendered ſo clear, pleaſing, and faſhionable, by the firſt edition of d'Alembert's Synopſis, as to be as implicitly believed in France, as Burnet's Theory of the Earth was in England, till examined by Keil, and proved to be founded on unphiloſophical principles. But a few years after, when d'Alembert had more accurately examined the principles of Rameau, and expreſſed his doubts of ſome of them in an article of the Encylopedie, Rameau was ſo irritated as to publiſh a pamphlet in his defence, in which he ſeems to have loſt all reſpect for his commentator; after which d'Alembert openly attacked his ſyſtem, and denied its being capable of demonſtration, which ſtaggered the liſt of French contra-puntiſts, who had thought there never was, nor ever could be, any accurate and good muſic compoſed, but on the principles of the *Baſſe fondamentale* of M. Rameau; which at preſent is as much neglected and forgotten in France, as, in the houſes of the great, ſmoking is in England.

DALEN, Corneille Van, called the Younger, a deſigner and engraver, the ſon of a print-ſeller of Antwerp, where he was born about the year 1626. He was placed under the tuition of Cornelius Viſſcher, whoſe ſtyle he generally adopted, though he ſometimes ſeems to have imitated the manner of Vorſterman, P. Pontius, Bolſwert, and other artiſts. Dalen acquired conſiderable reputation, and is ſaid by Fuſeli to have travelled into England; but this, probably, is only ſuppoſition, ariſing from his having engraved the portraits of ſeveral Engliſhmen. The prints of this artiſt are finely executed, and evince a correct taſte, and his heads in particular are in high eſtimation. He ſometimes marked his plates C. D. not unfrequently adding junior. Amongſt his numerous performances are the following: The four Fathers of the Church, a middling-ſized, upright plate, from Rubens; the Graces embelliſhing a Statue of Nature, a large print, on two plates, from the ſame, much in the manner of Bolſwert; the Virgin preſenting the Breaſt to the Infant Chriſt, middling ſized, from Flinck; Venus and Cupid, middling ſized, from the ſame; Charles II. in armour, a half-ſheet print, much eſteemed; four prodigiouſly fine portraits from Titian, generally conſidered the *chefs d'œuvres* of Van Dalen: 1ſt, Pietro Aretino, holding a book half open; 2d, Gio. Boccacio, holding a book ſhut; 3d, Giorgione da Caſtelfranco, ſeen in front; 4th, Sebaſtiano del Piombo. This latter is by ſome attributed to Tintoretto. Huber.

DALENS, Dirk, a painter, born at Amſterdam in 1659. He was inſtructed by his father, William Dalens, a landſcape-painter of no eminence. At the age of 13 he became acquainted, at Hamburgh, with John Voorhout, in whoſe company he applied himſelf to the pencil with unabated aſſiduity. He afterwards returned to Amſterdam, where he enjoyed conſiderable reputation during the remains of his ſhort life, which terminated at the age of 29, in 1688. A fine landſcape, with ducks and other fowl, painted by this artiſt, after the manner of Hondekoeter, is in the collection of the Elector Palatine. Deſcamps.

DALENAS, or Dalenes, in *Geography*, a ſmall town of Norway, in the dioceſe of Drontheim, with a provoſtſhip, to which belong ten pariſhes, and twenty-nine churches.

DALENBURG,

DALENBURG, a town of Germany, in the circle of Lower Saxony, and principality of Luneburgh Zell, on the Netze; 16 miles E. S. E. of Zell.

DALENE, a ſmall town of Norway, in the dioceſe of Chriſtianſand, with a provoſtſhip of five pariſhes.

DALFFEN, or DALFEN, a town of Holland, in the Overyſſel, ſeated on the Vecht; 8 leagues S. W. of Coverden.

DALFHEIM, a town of Germany, in the circle of the Lower Rhine, and palatinate of the Rhine; 6 miles N. W. of Worms.

DALHEIM, a town of Germany, in the circle of Weſtphalia, and duchy of Juliers; 3 miles N. N. W. of Waſſenberg.

DALHEM, or DALEM, a ſmall town of France, in the department of the Ourte, chief place of a canton, in the diſtrict of Liege, on the river Bervine; 6 miles N. E. of Liege, and 18 N. W. of Limbourg, with which it was annexed to France, in conſequence of the wars of the Revolution, having formerly belonged to the United Provinces of the Netherlands, at preſent the kingdom of Holland. Dalhem has 732 inhabitants, and its canton 19 communes, with a population of 13,622 individuals, upon a territorial extent of 62½ kiliometres. N. lat. 50° 45′. E. long. 8°.

DALIAS, a town of Spain, in the province of Grenada; 6 leagues W.S.W. of Almeria.

DALIN, OLOF VON, in *Biography*, a Swediſh hiſtorian and poet, was born in 1708 at Winberga, in Holland, where his father was clergyman. He was educated at Lund, and in 1735 he publiſhed, without his name, a weekly paper, entitled "the Swediſh Argus." This was ſo much eſteemed, that the author was appointed librarian at Stockholm in 1737; and from thenceforth he acquired great reputation by his literary productions, which obtained a very general circulation through the whole kingdom. In 1739 he began his travels, and in the courſe of the next four years viſited the principal places on the continent, and formed an acquaintance with many men of great learning and celebrity. In 1743 he publiſhed a poem, entitled "Swediſh Liberty," one of the beſt poetical productions that ever appeared in Sweden. He was next engaged to compile a hiſtory of his own country from the earlieſt period to the preſent time, which he accompliſhed in three volumes quarto; and which was afterwards tranſlated into the German language. In 1749 the hereditary prince was put under his care; the duties of preceptor he performed ſo much to the ſatisfaction of his employers, that he was ennobled in the year 1751, when he aſſumed the name of VON Dalin. In 1753 he was appointed a counſellor of the chancery, and in two years after hiſtoriographer to the king. He was next advanced to the dignity of knight of the polar ſtar, and counſellor of the court. This happened in the ſpring of 1763, and in the following Auguſt he died at the palace of Drotlingholm. He was a voluminous but very reſpectable writer, and his ſmaller pieces have been collected and printed in 6 volumes. General Biography.

DALIS, DALIA, or DALAND, in *Geography*. See DALECARLIA.

DALISANDUS, in *Ancient Geography*, a town of Aſia, in Cappadocia. Ptolemy.

DALKEITH, in *Geography*, a conſiderable town, though a ſmall pariſh, in the county of Mid-Lothian, Scotland, is delightfully ſituated on a ſtrip of land, between the rivers North and South Eſk; whoſe banks are richly clothed with trees, and ornamented with handſome ſeats of ſome families of diſtinction. *Dalkeith-houſe*, adjoining the village, the elegant ſeat of the duke of Buccleugh, was erected on the ſite of Dalkeith Caſtle, about the beginning of the laſt century. The thriving and luxuriant plantations around it, enlivened by the waters of two winding rivers, which unite about half a mile below, over one of which is thrown an elegant ſtone bridge, and the various walks laid out with much taſte, tend greatly to heighten the effect of the building. The park is well wooded, and ſtocked with deer. This place is much reſorted to by perſons from Edinburgh, and other parts of Scotland adjacent, for the purpoſe of being gratified with the ſurrounding and delicious ſcenery. A few manufactures have been lately introduced, but the principal trade is in corn; for which article one of the largeſt markets in the country is held here every Thurſday: the whole buſineſs of which is done for ready money. The grammar ſchool of Dalkeith has long been in high repute as an excellent ſeminary; and in this ſome of the brighteſt ornaments of literature Scotland has produced firſt received the rudiments of their education. The population of the pariſh in 1799, amounted to 4336, about 3000 of which reſided in the town. But this has ſince much increaſed.

DALKEY, a ſmall iſland in the Iriſh ſea, forming the ſouthern limit of the bay of Dublin. It contains about 18 acres, having plenty of herbage. The channel between this iſland and the main land is called *Dalkey Sound*, in which there is good anchorage for ſhips. The village of Dalkey, on the main land, is romantically ſituated at the northern baſe of a high mountain, commanding a beautiful view of the bay of Dublin. This village in the reign of queen Elizabeth, and during a great part of the 17th century, before the port of Dublin was improved, was the repoſitory of the goods belonging to the merchants of Dublin. Dalkey iſland is in long. 6° 4′ W. Lat. 43° 19′ N.

DALLAMANO, GUISEPPE, in *Biography*, a painter, born at Reggio, in 1679. This artiſt, though totally illiterate, and by ſome even ſaid to have been an idiot, poſſeſſed extraordinary talents for painting, and was eſpecially an excellent colouriſt. He lived many years in the ſervice of the court of Turin, and died in 1758. Lanzi.

DALLANS, RALPH, an organ-builder of conſiderable merit, and great practice in England, at the time of the Reſtoration. During the ſuppreſſion of the cathedral ſervice, and prohibition of the liturgy, ſcarce a tolerable inſtrument had been left entire in any church of the whole kingdom. Some of them had been ſold to private perſons, ſome robbed of their pipes for the ſake of the metal, and others totally deſtroyed by malignant fanatics. Except Dallans, Loofemore of Exeter, Thamar of Peterborough, and Preſton of York, there was not an organ-builder to be found in England. Theſe were employed with all the workmen that could be procured, in repairing the organs of ſome churches, and conſtructing new ones for others. Dallans was engaged to build a new organ for St. George's chapel, Windſor; which, perhaps, from the haſte with which it was conſtructed, though its appearance was beautiful and magnificent, did not prove ſo excellent as was expected. He alſo erected, among a great variety of others for different places, the organ at New College, Oxford; and an upright organ, with four ſtops, for the public muſic ſchool in that univerſity, eſtabliſhed ſoon after the reſtoration. The price of this laſt inſtrument was only fifty-one pounds ten ſhillings; as appears from a printed account of inſtruments, books, and other neceſſaries, bought for the uſe of the muſic-ſchool with money contributed for that inſtitution.

The time of Dallan's deceaſe was nearly aſcertained by an inſcription on a ſtone in the Old Church of Greenwich, which is thus recorded by Strype:

"Ralph Dallans, organ-maker, deceaſed while he was making this organ; begun by him February 1672. James White, his partner, finiſhed it, and erected this ſtone 1673."

DALLER, or DAHLER, in *Geography*, a ſmall town of Denmark, in that part of Sleſwick which is conſidered as belonging to North Jutland, in the peninſula of Jutland.

DALL-JOSEPHAT, a dale, in Southern Africa, which, together with Waagenmaker's valley, is encloſed between the hilly projections that branch out towards the north or upper end of the valley of Drakenſtein. The beſt oranges, as well as the beſt peaches, and other fruit, are ſaid to be produced in theſe dales; and the wines are among the firſt in quality.

DALLOWICZE, a town of Lithuania, in the palatinate of Minſk; 32 miles N.E. of Minſk.

DALMACHERRY, a town of Hindooſtan, in the Myſore country; 100 miles N.E. of Bangalore, and about the ſame diſtance N.W of Madras. On the ſituation of Dalmacherry and Gooty, depends the whole courſe of the river Pennar, from its ſource to Cuddapa; together with all its branches, and the different poſitions near them. Concerning the poſition of Dalmacherry, ſays major Rennell, there is a diverſity of opinion, its bearing and diſtance not having been mathematically aſcertained. This accurate geographer places it 56½ geographical miles from Arcot, in a N.N.W. direction; which makes the interval between it and Cudapanatum, 46½; and its latitude is 13° 43′ 30″. There are three important paſſes, that lead from this place into the Myſore and Cuddapah countries; and here it was that Doaſt Ally, the nabob of Arcot, was ſurpriſed and defeated by the Mahrattas, in the year 1740.

DALMANUTHA, in *Ancient Geography*, a place of Paleſtine, on the other ſide of Jordan, on the coaſt of the ſea of Galilee.

DALMASIO, LIPPO, in *Biography*, a painter who was native of Bologna, and flouriſhed in the 14th century. He ſtudied under Vitale, and, on account of the beautiful expreſſion which he gave to his heads of the Virgin, was called by his maſter *Lippo delle Madonne*, which name he afterwards preſerved. Pope Gregory XIII. ſo highly valued one of Lippo's Madonnas, that he always kept it near his bed-ſide as an incitement to devotion; and Guido Reni could not conceive how the artiſt could give to theſe heads ſo much majeſty, holineſs, and ſweetneſs of expreſſion, without divine inſpiration. He painted many works in the different churches and palaces of Bologna. In 1408, at an advanced age, he was ſaid to have taken the Carmelite habit. Later authors, however, have diſcovered that he died in the connubial ſtate about the year 1410. Malvaſia. Lanzi.

DALMATÆ, in *Ancient Geography*, a people reckoned by Strabo among the Illyrian nations, and who gave their name to a part of Illyria, which they occupied.

DALMATIA, an extenſive country of Europe, towards the Adriatic ſea, which anciently formed a part of Illyria. It was ſeparated towards the north from Liburnia by the river Titius, and on the ſouth-eaſt it had Naro. According to ancient tradition, it abounded with gold. Martial, in one of his epigrams, called it the land which produced gold. The principal rivers were the Titius, which watered the towns of Burnum and Sardona; the Tilurus, which paſſed near a hill on which was ſeated the town of Equum; and the large river Naro. Its chief towns were Scardona, Arbuda, Burnum, Promona, Tragarium, Sicum, Salones, Aſpalathos, Andetrium, Equum, Epetium, Cnæum, Peguntium, Bataneum, Narona, and Delminium. When the Avari obtained poſſeſſion of this country, it was afterwards denominated by the Chriſtians *Pagania*, becauſe the Avari were idolaters: the Illyrians called it Poganin. Pogania was divided into three diſtricts or zupanies. Mocros, formerly called Bataneum, was the moſt conſiderable town.

DALMATIA, or *Delmatia*, in *Geography*, from its ancient capital *Delmium* or *Delminium*, which the Romans took and deſtroyed in the 597th year of Rome, is a country of Europe between the 42d and 46th degree of north latitude; bounded on the north by Boſnia and Croatia, on the eaſt by Servia and Turkey in Europe, and on the weſt and ſouth by the Adriatic ſea, or gulf of Venice. It is 336 miles long, and 69 miles broad. In the year 1783, the number of its inhabitants was ſuppoſed to be 367,000. It was at that time divided between four different powers; one part belonged to Auſtria, and was ſtyled Hungarian Dalmatia; another belonged to the Italian republic of Venice, and has ſince paſſed under the ſovereignty of Auſtria, along with the Venetian ſtates, but is at preſent in the hands of the French; the third part belonged to the little republic of Raguſa, which part, together with Raguſa itſelf, is likewiſe occupied by French troops; and the fourth belonged to the Ottoman Porte, and was called Turkiſh Dalmatia.

Hungarian Dalmatia lies in the upper part of the Adriatic ſea, and compriſes, beſides the country of the Uſcocks and Morlachia, the diſtrict of Zengh, on the confines of Iſtria, the diſtrict of Ottoſchatz, the county of Lyka or Licca, part of which belongs to Turkey; the weſtern part of the county of Corbau; and the Zwonigrad or Serman diſtrict. Zengh or Segna, and Ottorichatz, are its principal towns.

Venetian Dalmatia was divided into the continent, and the county of Zara. Its inhabitants are conſidered as ſkilful mariners; at leaſt, they are the beſt in the Adriatic. They reſemble the Savonians in their manners, and ſpeak the ſame language. The country is mountainous and rather barren. The principal towns are ſituated on the coaſt. Zara is the capital.

Raguſan Dalmatia, which belonged to the republic of Raguſa, conſiſted only of that city and a territory of about ſixty miles in length, with the towns of Gravoſa and Stagno, and five ſmall iſlands, the principal of which is Melida, Milet or Melada. See RAGUSA.

Turkiſh Dalmatia is ſituated between Boſnia, and Venetian and Raguſan Dalmatia. It extends from Boſnia to Albania. Its chief places are Moſtar or Maſter, Clinovo or Klinova, and Scardona or Skardin.

Dalmatia, after it had been reduced under the Roman yoke, ſhook it off not leſs than five times, and for the ſpace of 220 years gave the Romans much trouble, until the reign of Auguſtus, when, the provinces being divided between him and the ſenate, Dalmatia fell to the latter; but the ſenate voluntarily ceded this province to the emperor, who appointed a quæſtor over it. At the death of Conſtantine the Great, Dalmatia was conſidered as a part of Illyricum. It ſuffered very much from the inroads of the northern barbarians, and was forced to ſubmit to the Goths; but it was reconquered, along with Italy, by the emperor Juſtinian. The Slavi or Slavonians, at laſt, eſtabliſhed themſelves in Dalmatia about the end of Heraclius's reign. The country had then its particular kings, the laſt of whom dying without iſſue, left his kingdom to his conſort, who bequeathed it to her brother Ladiſlaus, king of Hungary. In the fifteenth century, the Venetians conquered the whole kingdom of Dalmatia, and reſtored only a portion of it to the Hungarians, keeping the beſt maritime parts. The Turks afterwards diſpoſſeſſed the Venetians of ſome provinces, and a ſmall maritime territory was allotted to the republic of Raguſa.

The

The Dalmatians uſe the Slavonian language and cuſtoms; and profeſs the Roman Catholic religion. Its rivers, which have no long courſe, are moſtly navigable. The country is interſperſed with mountains; but theſe are not unfruitful, as they produce olives, vines, myrtles, and a great variety of vegetables; and within them, it is ſaid, there are mines of gold and ſilver ore. The air is pure and temperate.

Dalmatia being now the ſcene of bloody conteſts, its fate will perhaps be decided before we arrive at the article *Montenegrins*, which will give us an opportunity to reſume this account. See MONTENEGRINS.

DALMATIAN ISLES, *the*, are ſeveral iſlands in the Adriatic, on the coaſt of Venetian Dalmatia, which formerly belonged to Venice, the principal of which are Oſero, Cherſo, Veglia, Arbe, Pago, Lantano, Paſma, Iſola longa, Mortero, Brazza, Leſina, Liſſa, Curzola nigra, or Corcyra. Many of theſe iſles are fertile in wine, olives, figs, and other fruits.

DALMATIAN *Chain*, is a vaſt chain of mountains which proceeds by the north of Dalmatia towards the Hæmus, and is known by many local appellations, as mount Promina, near Gnin, mount Prologh, mount Clobu. The latter mountains are chiefly calcareous. Pinkerton's Geography, vol. i. p. 388.

DALMATIC, an ancient clerical habit, ſo called, becauſe it was previouſly the ordinary dreſs of the inhabitants of Dalmatia. It covered the whole body, and had large looſe ſleeves; on which account it was thought to be convenient for the miniſtry of the deacons. But it was alſo worn by biſhops, as we learn from the acts of St. Cyprian, the celebrated doctor and martyr of the third century, who being about to ſuffer death, delivered his dalmatic to his deacon, leaving the reſt of his dreſs for the executioners. At preſent it forms part of the under-dreſs of Roman Catholic biſhops, when they officiate pontifically, being made of thin, light ſilk. But it is the outſide and diſtinctive veſtment of their deacons, being richly ornamented with lace, and having a ſort of large open wings attached to it, by way of ſleeves.

DALRYMPLE, SIR DAVID, in *Biography*, a lawyer and hiſtorian of ſome eminence in Scotland, was born in 1726. He was educated at Eton, where he made a rapid progreſs in the learned languages, and formed a predilection for Engliſh manners and cuſtoms. From Eton he went to Utrecht, where he ſtudied the civil law, and remained till the year 1746. He was called to the bar, in his own country, in 1748; but as an advocate he was far from ſhining, though he poſſeſſed much and ſound learning, and was capable of arguing any caſe very forcibly. He was appointed one of the judges of the court of ſeſſion early in the year 1776, and ſoon after, one of the lords commiſſioners of juſticiary; on this occaſion he aſſumed the title of Lord Hailes, the name by which he is generally known among the learned of Europe. He diſtinguiſhed himſelf in this ſituation by ſtrict integrity, patient attention, and uniform decorum of behaviour. In doubtful caſes he always inclined to mercy, and he was free from that bias towards the crown with which many of the judges in the Scotch courts have often been charged. As a public man, his character has been given in few words: he was a ſound lawyer, and an upright judge. In private life, he was eminent as a profound and accurate ſcholar; deeply read in the claſſics, and well acquainted with every department of the belles lettres, and with hiſtorical antiquities, particularly of his own country. Lord Hailes publiſhed many works, but thoſe which chiefly demand our notice, are, 1. "Annals of Scotland, from the Acceſſion of Malcolm Canmore, to the Acceſſion of the Houſe of Stuart," in 2 vols. 4to. This work is ſo well authenticated by references to hiſtorians of good credit, or to deeds and writings of undoubted authority, that it will long remain a laſting monument of the induſtry, learning, and integrity of the worthy author. 2. Lord Hailes came forward, in conjunction with the preſent biſhop of Landaff and others, to repel Mr. Gibbon's attack on Chriſtianity. He publiſhed a volume, entitled "An Inquiry into the Secondary Cauſes which Mr. Gibbon has aſſigned for the rapid Progreſs of Chriſtianity," in which there is a great diſplay of literary and critical acumen, and of zeal for the cauſe of religion, without any of the rancour too often mixed with theological controverſy. This was publiſhed in 1786, and was the laſt work of conſequence that he ſent to the preſs. The infirmities of age came now rapidly on his lordſhip; he nevertheleſs was enabled to attend his duty on the bench till within three days of his death, which happened on the 29th of November 1792. Lord Hailes was author of many pieces connected with his profeſſion, as a lawyer; of ſome biographical ſketches of the natives of Scotland; and of eſſays in many of our periodical works. Encyc. Brit.

DALRYMPLE'S *Point*, in *Geography*, a cape of the iſland of Dominica; 2 miles S. of Charlotte's town.

DALTON, JOHN, in *Biography*, an eminent divine of the church of England, was ſon of the Rev. John Dalton, rector of Dean, near Whitehaven, where he was born, in the year 1709. He was educated at Queen's college, Oxford, and became tutor to lord Beauchamp. During this period, he adapted Milton's Maſk of Comus to the ſtage, by the inſertion of ſeveral ſongs and different paſſages ſelected from Milton's other works, as well as of ſeveral additions of his own, ſuited to the characters and to the manner of the original author. This was favourably received by the public, and Mr. Dalton very induſtriouſly ſought out a grand-daughter of the poet, who was borne down with age and poverty; and procured her a benefit from it, the profits of which amounted to a conſiderable ſum. He went abroad with his pupil, who died in the courſe of his travels. On his return, Mr. Dalton took orders, and obtained the rectory of St. Mary Hill, London. He was afterwards promoted by the king to a prebend of Worceſter, where he died, July, 1763. He was author of a volume of ſermons; of a deſcriptive poem, addreſſed to two ladies on their return from viewing the coal-mines; and remarks on twelve hiſtorical deſigns of Raphael; and the Muſæum Græcum et Egyptiacum. His brother Richard was librarian to the king, and publiſhed drawings, executed by himſelf, of the proceſſion to Mecca.

DALTON, in *Geography*, a ſmall market town of England, in the county of Lancaſter, and that part of it called *Furneſs*. It probably received its name from the Saxons: the term, in their language, ſignifying a place ſituated in a *dale* or *valley*. Thus, in the midſt of a moſt fertile tract of country, it originally derived its hiſtoric conſequence, from its being connected with Furneſs abbey. By a privilege granted to the abbot by king Stephen, Dalton became the capital of Furneſs, flouriſhed under its auſpices, and held that rank till the diſſolution of its monaſtery. Subſequent to that period, it began to decline. Ulverſton, in the vicinity, being more advantageouſly ſituated for trade, ſoon obtained the preference in a commercial view. Dalton conſiſts of one principal ſtreet, opening into the market-place; and ſome of the old houſes having been lately replaced by better buildings, its appearance has been much improved.

The

The church is a ſmall neat building, having an organ, the expence of which was defrayed by voluntary ſubſcription. The tenure of property in this place is peculiar. The place is divided into four portions, or townſhips, and the cuſtomary tenements in each are of equal ſize; pay equal parts of rent to the lord; are not deviſeable by will; and cannot be ſeparated by the proprietor. This peculiarity aroſe out of the feudal ſyſtem, variouſly modified in religious caſes; as every tenant formerly was obliged to furniſh the abbot with a man and horſe for the ſervice of the king.

The only trade of any conſequence, at preſent, is that of making malt. It has a weekly market on Saturdays, and three annual fairs. The moſt ancient is held October 23d, another on June 6th, and a third on April 28th. According to the reports ſent to government, the population of "Dalton in Furnace" is ſtated to be 303, occupying 56 houſes; and that of "Dalton," a hamlet, 1052 perſons, occupying 224 houſes. In this town, at a place called the *Beckſide*, was born, December 15th, 1734, George Romney, a painter of great genius, who obtained conſiderable eminence in his profeſſion: he died, and was interred at this his native place, Nov. 15th, 1802. On an eminence, called *High Haume*, about a mile to the north of the town, is a circular intrenched mound, which appears to have been a fortified beacon: and on the weſt ſide is a rocky eminence, with a ſquare tower upon the ſummit, probably built to guard the approach to the abbey. In this fortreſs the abbots held their ſecular courts, and immured their priſoners. The building contains three floors, and is uſed to hold the courts-leet and baron of the chief lords of the liberty and manor of Furneſs. Theſe are lord Beaulieu and the duke of Buccleugh. Near Dalton, at the diſtance of one mile and a half, are the ruins of the once extenſive and celebrated monaſtery of Furneſs. It was a Ciſtertian abbey, and, in point of wealth and magnificence, was conſidered the ſecond in the kingdom; being inferior to none, either in liberal endowment or extent of privilege, except that of Fountains, in the county of York. The majeſtic ruins of this once proud pile, from the deep retirement of the ſituation, the venerable grandeur of its fine-pointed arches, and the luxuriant trees, which caſt a gloom of ſhade in uniſon with its fallen grandeur, render it a highly pictureſque intereſting ſcene, which is much frequented and admired by the votaries of taſte and lovers of antiquity.

Dalton, a fine townſhip of America, in Berkſhire county, and ſtate of Maſſachuſetts, having Pittsfield on the Weſt, and containing 859 inhabitants. It was incorporated in 1784, and lies 135 miles W. by N. from Boſton, and about 36 miles in the ſame courſe from Northampton, the ſtage road from Boſton to Albany.—Alſo, a townſhip in Grafton county, N. Hampſhire, firſt called Apthorpe, incorporated in 1784, and containing 62 inhabitants; ſituate on the eaſt bank of Connecticut river, oppoſite to Concord, in Eſſex county, Vermont.

DALUA, or Awin Dalua, *i. e. The Double Stream*, ſo called from its two ſources, a river of Ireland, which, riſing in the N.W. corner of the county of Cork near Kerry, paſſes the town of Newmarket, and meets the Allo at Kanturk.

DALUS, in *Antiquity*, a certain meaſure of land; whence comes *dali*. The *dali prati* have been eſteemed ſuch narrow ſlips of paſture, as are left between the ploughed furrows in arable land; which, in ſome parts of England, are called *doles*. The word is applied in Welſh to low meadows by a river ſide. This ſeems alſo to be the original and nature of Deal in Kent, where Cæſar landed and fought the Britons. Cowel.

DAM, a boundary or confinement, as to dam up, or dam out: *infra damnum ſuum*, within the bounds or limits of his own property or juriſdiction. Bract. lib. ii. cap. 37.

Dam denotes a bank of earth or other matter, which pens up water, as a mill-dam; ſometimes the ſheet, or pound of Wales itſelf, is called the *dam*. See Embankment.

Dam, a money of account in the Mogul empire, which is the fortieth part of a rupee, or 2*s*. 6*d*. ſterling, and ſerves for computing the land revenues.

Dam, or *Appinge Dam*, *Damme*, *Dammona*, in *Geography*, a ſmall town of Holland, in the department of Groeningen, on the river Fivel, which, from this place, is called the Damſter Diep, about three miles from the ſea, 15 N E. of Groeningen, and 18 S.W. of Embden. N. lat. 53° 36′.—Alſo, a ſmall town of France, in the department of the Lys, not far from the ſea, and 5 miles N.E. of Bruges. N. lat. 51° 14′.

DAMA, a town of Arabia, in the country of Yemen; 220 miles N.N.E. of Mecca.

Dama, in *Zoology*. See Cervus, Antelope and Nanguer, Lucanus, and Phalæna *nocua*.

DA'MA, in *Ship-Building*, a reſinous ſubſtance uſed in India for paying the bottoms of ſhips. In ſome parts of that country, the planks are rabbeted into each other, the interſtices are filled with cotton, and the whole of the ſhip's bottom being payed with dáma, preſents, as it were, one impenetrable ſurface, as impervious to the water as it is poſſible for any ſubſtance, in the ſlighteſt degree porous, ſhould be.

DAMAC, in *Geography*, a town of the iſland of Java, on the north coaſt, where the Dutch have a factory.

DAMAGE, in *Law*, is generally taken for any hurt, or hindrance that a man receives in his eſtate; but more particularly for a part of what the jurors are to inquire of and bring in, in paſſing verdict for the plaintiff, in a civil action, be it perſonal or real. After verdict given of the principal cauſe, they are aſked their conſciences touching coſts and damages, which contain the hindrances that the plaintiff or demandant hath ſuffered by means of the wrong done him by the defendant or tenant. Damage has two ſignifications; the one proper and general, the other ſtrict and relative. *Proper*, as it is in caſes where damages are founded on the ſtatute of 2 Hen. IV. cap. 1, and 8 Hen. VI. cap. 9, where coſts are included within the word damages. Damage then, in its proper ſignification, is ſaid *à demendo*, when, by diminution, a thing becomes worſe; and in this ſenſe coſts of ſuit are damages to the plaintiff, as by them his ſubſtance is diminiſhed.

Relative is when the plaintiff declares the wrong done him to the damage of ſuch a ſum. This is to be taken relatively, for the wrong which paſſed before the writ brought; and is aſſeſſed by reaſon of the treſpaſs aforeſaid; and cannot extend to coſts of ſuit, which are future and of another nature. 10 Rep. 116, 117. See Costs.

In *perſonal* and *mixed* actions, damages were recovered at common law. But in *real* actions, no damages were recoverable, becauſe none were demanded by the count or writ: whereas, in actions *perſonal* the plaintiff counts *ad damnum* for the injury, and if he recovers no damages, he hath no coſts. (10 Rep. 111. 117.) In a *perſonal* action, the plaintiff ſhall recover damages only for the tort done *before* the action brought; and therein he counts for his damages. In a *real* action, he recovers his damages pending the writ, and therefore never counts for his damages. (10 Rep. 117.) By the ſtatute of Glouc. 6 Ed. I. c. 1. damages are given in real actions, aſſiſes of novel diſſeiſin, mort d'anceſtor, &c., and ſhall be recovered againſt the alienee of a diſſeiſor, as well

as againſt the diſſeiſor himſelf; and the demandant ſhall have of the tenant likewiſe coſts of ſuit; but not expences for trouble and loſs of time. (2 Inſt. 288.) See alſo the ſaid ſtatute (6 Ed. I. c. 1. 3 Hen. VII. c. 10. 2 Inſt. 284. 286. 2 Danv. Abr. 448.) Damages ſhall be recovered in writ of admeaſurement of dower; but not in a writ of admeaſurement of paſture. (2 Danv. 457.) Damages and coſts are due in a writ of annuity; and if the jury find for the plaintiff, and do not aſſeſs damages, it will be error; though he may after verdict releaſe the damages, and take judgment for the annuity. (11 Rep. 56. Dyer, 320. 369.) In battery, impriſonment, and taking of goods, againſt three perſons; one commits the battery, another the impriſonment, and the third takes the goods, all at one time, all are guilty of the whole, and to be charged in damages. 3 Lev. 324. 10 Rep. 66. 69.

In *real* actions, damages are aſſeſſed by writ of inquiry; and when the jury find the iſſue for the plaintiff, they are to aſſeſs the damages. And in actions upon the caſe, &c. where damages are uncertain, it is left to the jury to inquire of them. In debt, when it appears certain to the court what it is, the damages aſſeſſed by the jury are very ſmall, or, in fact, only nominal, as one ſhilling; and the maſter in B. R. taxeth the coſts, which are added thereto, and called damages. (1 Lill. 390.) When judgment is given by default, in action of debt, the court is to aſſeſs the damages, and not the jury: thus alſo, in judgment by *nil dicit*, in action of debt. In caſe of exceſſive damages being given, the court hath ſometimes relieved the defendant by a new writ of inquiry. (2 Danv. 464.) And in caſe of exceſſive damages, on motion, the defendant may have a new trial. (1 Neſſ. Abr. 587.) A jury may, and now frequently do, give intereſt on book-debts, in the name of damages. (Doug. 676.) In action upon the caſe, the jury may find leſs damages than the plaintiff lays in his declaration, but ought not to find more: the plaintiff may releaſe part of the damages, upon entering up his judgment. (10 Rep. 115.) Double, treble damages, &c. are allowed in ſeveral caſes, by a great variety of ſtatutes; as for not ſetting forth tythes; diſtreſſes wrongfully taken; reſcous; though, if it be not found by the jury, that the plaintiff hath ſuſtained ſome damage, in caſes where treble damages, &c. are inflicted by law, no damages can be awarded. 2 Danv. Abr. 449.

Damage-*clear*, *Damna Clericorum*, was a fee aſſeſſed out of all damages exceeding five marks, and recovered to the amount of the tenth part in the court of common pleas, and the twentieth part in the courts of king's bench and exchequer, which the plaintiff was obliged to pay as a gratuity to the prothonotaries and his clerks, for drawing ſpecial writs and pleadings; but is aboliſhed by ſtat. 17 Car. II. cap. 6: and if any officer in the king's courts take any money in the name of damage-clear, or any thing in lieu of it, he ſhall forfeit treble the value.

Damage-*feaſant*, or *faiſant*, is when a ſtranger's beaſts are doing hurt, or ſpoiling the graſs, corn, woods, &c. of another man, without his leave or licence.

In this caſe, the party whom they damage may diſtrain, and impound them, both by night, and by day; though in other caſes, as for rent, ſervices, &c. none may diſtrain in the night. (Stat. 51 Hen. III. ſtat. 4. 1 Inſt. 142) If a man take my cattle and put them into the land of another, the tenant of the land may take theſe cattle damage-feaſant, though I, who am the owner, was not privy to the cattle's being there damage-feaſant; and he may keep them againſt me till ſatisfaction of the damages. (2 Danv. Abr. 364.) But if one comes to diſtrain damage-feaſant, and to ſeize the cattle, and the owner drives them out before they are taken, he cannot diſtrain them damage-feaſant, but is put to his action of treſpaſs; for the cattle ought to be actually upon the land damage-feaſant, at the time of the diſtreſs. (1 Inſt. 161. 9 Rep. 22.) Beaſts of huſbandry, ſheep, horſes joined to a cart, and, as it is ſaid, a horſe with a rider on it, may be diſtrained damage-feaſant, though not for rent. (1 Sid. 422. 440.) But the owner may tender amends, before the cattle are impounded; and then the detainer is unlawful: alſo, if, when impounded, the pound-door is open, the owner may take them out. (5 Rep. 76.) If men are rowing up my water, and endeavouring with nets to catch fiſh in my *ſeveral* piſcary, I may take their oars and nets, and detain them as damage-feaſant, to ſtop their further fiſhing; though I cannot cut their nets. Cro. Car. 228.

DAMALN, in *Geography*, a town of European Turkey, in the Morea; 40 miles S.E. of Napoli di Romania.

DAMAN of *Iſrael*, in *Zoology*. See Dipus.

DAMANHOUR, or Demenhur, in *Geography*, a town of Egypt, ſituated near the canal of Alexandria, and the capital of the province of Bahira; 32 miles E S.E. of Alexandria. This town is large, but ill-built, moſt of the houſes being conſtructed of earth or bad brick. It is the reſidence of the bey, or governor of Bahira, and of a kiaſchef, or particular commandant, and alſo of a garriſon of janizaries; and it is the centre of the trade of the cotton that is gathered in the extenſive and beautiful plains by which it is ſurrounded. It is there picked from the buſhes, beaten, carded, and ſpun; and in theſe different operations conſiſts the chief employment of the greater part of the inhabitants. This town is infeſted by a number of courteſans, who practiſe various arts of ſeduction, and who contribute to deprave the manners of the people, notwithſtanding the agricultural and commercial occupations in which they are employed. This town, which is inhabited by Copts and Mahometans, is the Hermopolis parva of Ptolemy, and is called Damanhour from the deſart. The neighbouring country produces a great deal of flax, corn, and barley, as well as cotton.

DAMANIA, in *Ancient Geography*, a town of Spain, between Lobetum to the weſt, and Edeta to the ſouth-eaſt; ſeated near the left bank of the river Turia.

DAMAPETTA, in *Geography*, a town of Hindooſtan, in the country of Golconda; 45 miles N.W. of Rajamundry, and 140 E. of Hydrabad.

DAMAR, a town of Arabia, in the highlands of Yemen, ſeated on a fertile plain between Jerim and Sana. It is the capital of a province, and is governed by a dola, who reſides in a large caſtle. It has a famous univerſity or college for the Zeidites, commonly containing 500 ſtudents. Damar has no walls; its buildings are good; and it is very large, the number of houſes being about 5000. The Jews live in a detached village; but the Banians are allowed to live in the town among the Muſſulmans. Near Damar is a mountain containing a mine of native ſulphur; and in another hill, ſomewhat further diſtant, are found thoſe fine cornelians which are ſo much eſteemed in Arabia.—Alſo, a town of of Arabia, in the province of Oman, 70 miles N. of Oman.

DAMARAS, the inhabitants of a diſtrict in the colony of the Cape of Good Hope, whoſe country is ſo barren and ſandy that they cannot keep cattle.

DAMASAN, or Damazan, a ſmall town of France, in the department of Lot and Garonne, chief place of a canton in the diſtrict of Marmande, 18 miles W. of Agen. It contains 979 and the canton 7213 inhabitants, in 11 communes, and upon a territorial extent of 172½ kiliometres.

DAMASCENA, in *Ancient Geography*, a country of Aſia, in Cœle-Syria, deriving its name from Damaſcus, which is ſituated in this country.

DAMASCENUS, John, in *Biography*, a learned Chriſtian father in the eighth century, was born at Damaſcus. His father, though a Chriſtian, was alſo counſellor of ſtate to the caliph of the Saracens. He was educated by a monk at Jeruſalem, who had been redeemed by his father from ſlavery, and under whoſe inſtructions he made great progreſs in mathematical and philoſophical learning. He ſucceeded his father in the caliph's court; but his religious zeal rendered him obnoxious to the emperor, whoſe ſervice he was obliged to quit. From the ſplendour of a court he retired to a monaſtery, determining to devote himſelf to ſtudy, and the ſeverity of the cloiſter. He was ordained a prieſt towards the latter end of his life by the patriarch of Jeruſalem, and died about the year 750. He was author of a great variety of pieces in theology, philoſophy, and eccleſiaſtical hiſtory, which exhibit ſtriking proofs of extenſive erudition and eminent talents. The beſt edition of Damaſcenus's works conſiſts of two vols. fol. printed at Paris, in 1712. The Arabians were much indebted to this Chriſtian philoſopher for their deliverance from barbariſm. Among his writings is an explanation of dialectics under the title of "Heads of Philoſophy;" "Diſſertations on the three Parts of the Soul;" "An accurate Delineation of the orthodox Faith." This latter work, ſays Dr. Enfield, is perhaps the firſt attempt that was made to apply the language and arrangements of the peripatetic philoſophy to theology, and to form what has ſince been called a "body of divinity." Hence ſome have conſidered this Chriſtian father as the father of the ſcholaſtics. His example was afterwards followed by a long train of Chriſtian writers. To him, therefore, ought to be aſcribed, in a great meaſure, the miſchiefs which aroſe from the alliance which he introduced between the doctrines of Chriſt and the dogmas of Ariſtotle. Moreri. Brucker by Enfield. *John Damaſcenus* is celebrated by the writers of his life, and by eccleſiaſtical hiſtorians, as the compiler and reformer of chants in the Greek church, in the ſame manner as St. Gregory in the Roman. And Leo Allatius (De Libris Eccleſ. Græcorum) under the title *Octoëchus* (Οκτωήχος, eight Tones), tells us they were compoſed by J. Damaſcenus. Zarlino goes ſtill farther, and informs us (Inſtit. Harm. 4ta. parte. cap. viii.) that in the firſt ages of Chriſtianity the ancient Greek notation by letters having been thrown aſide, John Damaſcenus invented new characters, which he accommodated to the Greek eccleſiaſtical tones; and that theſe characters did not, like ours, merely expreſs ſingle ſounds, but all the intervals uſed in melody: as a ſemitone, tone, third minor, third major, &c. aſcending and deſcending, with their different duration. This reſembles, in many particulars, the notation of the eccleſiaſtical books of the Romiſh church, before the time-table and characters in preſent uſe were invented, or, at leaſt, generally received.

DAMASCIUS, a gentile philoſopher, was born at Damaſcus, and flouriſhed in the ſixth century. He ſtudied at Athens and Alexandria under the ableſt maſters of the age in which he lived. Theon was his maſter in rhetoric, and him he ſucceeded in his office, as he did alſo Iſidorus as teacher of philoſophy at Athens. From Athens he went to Alexandria, and preſided in the philoſophical ſchool in that city; but he was obliged to withdraw, on account of the perſecutions which were exerciſed at that period by the emperor Juſtinian againſt the gentile philoſophers. Damaſcius fled to Perſia, and after this we have no certain accounts of what happened to him. He was author of the "Lives of Iſidorus and others." He wrote alſo "Commentaries on Plato;" and a treatiſe "concerning things extraordinary and ſurprizing." All his works are marked with the characters of the eclectic ſchool, obſcurity, fanaticiſm, and impoſture. Moreri. Brucker by Enfield.

DAMASCUS, in *Geography*, a celebrated town of Aſia, once the metropolis of Syria, and, in the time of Strabo, a moſt conſpicuous city. The emperor Julian, ſurnamed the Apoſtate, ſtyles it "the eye of all the Eaſt, the ſacred and moſt magnificent Damaſcus;" and commends it on account of its temples, fountains, rivers, and alſo the richneſs and fertility of its ſoil. It was ſituated, at the diſtance of 50 miles from the ſea, from which it was ſeparated by lofty mountains, on two rivers, *viz.* Amanah or Abara, which paſſed through it, and Parphar, called by the Greeks Chryſorrhæa, which ran on the outſide of its walls. Some ancient writers have aſcribed its origin to one Damaſcus, who built it, and from whom it derived its name; but the more generally received opinion is, that it was founded by Uz, the eldeſt ſon of Aram. (Bochart, Geog. Sacr. l. ii. c. 8. Oper. t. i. p. 80). However this be, Damaſcus ſubſiſted in the time of Abraham, and may be reckoned one of the moſt ancient cities now in being. Some have ſaid, that Abraham reigned in this city immediately after its founder Damaſcus. According to Joſephus, Adad was the firſt perſon who aſſumed the title of king of Damaſcus; and he was vanquiſhed by David. It was captured and ruined by Tiglath-Pileſſer, king of Aſſyria, who carried away captive its inhabitants to Kin, on the other ſide of the Euphrates, B. C. 740; thus fulfilling the predictions of the prophet Iſaiah (xvii. 1—3.) and Amos (i. 4, 5.) It was alſo taken by Sennacherib, and by the generals of Alexander the Great. Metellus and Lælius ſeized it during the war of Pompey with Tigranes the Great, B. C. 65; and it remained under the dominion of the Romans, until the Saracens took poſſeſſion of it about A.D. 634. Under Auguſtus, Obodas, father of Aretas, king of Arabia, was ruler of Damaſcus; and Aretas was governor when St. Paul was there. It continued for a long time ſubject to the emperors, and was one of the five arſenals which they had in the eaſt. After ſeveral revolutions and viciſſitudes, (for an account of which ſee Syria,) Damaſcus was beſieged and taken, A.D. 1400, by Tamerlane, who put all the inhabitants to the ſword. When the Egyptian Mamelukes gained poſſeſſion of Syria, they repaired Damaſcus. Selim, emperor of the Turks, took poſſeſſion of Syria, A.D. 1516, after the battle of Aleppo, in which the Mamelukes were defeated; and it ſtill remains a province of the Turkiſh dominions. It was from the territory of this city, that the prunes of Damaſcus, called by the Romans "pruna Damaſcena," derived their name.

Damaſcus is now the capital of a pachalic. (See the next article.) The Arabs call it *El-ſham*, and the oriental name of *Demeſhk* is known only to geographers. It is ſituated on an extenſive plain, occupied by gardens to the length of more than 3 leagues, and the breadth of more than 1½ league. Its walls are of a circular form, and the ſuburbs large and irregular. It is open to the ſouth and eaſt, and ſhut in towards the weſt and north by mountains, which limit the view at no great diſtance. The rivulets which flow from the adjacent mountains render the territory of Damaſcus the beſt watered and moſt delicious province of all Syria; the Arabs ſpeak of it with enthuſiaſm; and think they can never ſufficiently extol the freſhneſs and verdure of its orchards, the abundance and variety of its fruits, its numerous

merous ſtreams, and the clearneſs of its rills and fountains. This is the only part of Syria in which are detached pleaſure-houſes in the open country.

The ſoil, though poor, gravelly, of a reddiſh colour, and therefore ill adapted to corn, is more ſuitable to fruits, which are here excellently flavoured. No city contains ſo many canals and fountains; each houſe has one; and all theſe waters are furniſhed by three rivulets, or branches of the ſame river, called Barrady or Barradé, which, after fertilizing the gardens for a courſe of 3 leagues, flow into a hollow of the deſert to the ſouth eaſt, where they form a moraſs called "Behairat-el-Merdi," or the lake of the meadow. Damaſcus, though poſſeſſing various advantages, is ſtill deficient in point of ſalubrity. The white waters of the Barradé are cold and hard; and the natives are ſubject to obſtructions; the whiteneſs of their ſkin is rather the paleneſs of ſickneſs than the hue of health; and the immoderate uſe of fruit, particularly of apricots, however excellent in their kind, occaſions, every ſummer and autumn, intermittent fevers and dyſenteries. It is ſaid, however, that the air or water of Damaſcus, or both, operates powerfully againſt the leproſy. Damaſcus is much longer than it is broad. Its walls, which are neither ancient nor lofty, are ſtrong. They have nine gates. M. Niebuhr, who has given a plan of the city, eſtimates it at 3250 toiſes, or ſomewhat leſs than 1½ league in circumference. Comparing theſe dimenſions with thoſe of Aleppo, Volney ſuppoſes that Damaſcus may contain 80,000 inhabitants. Browne, in his Travels in Africa, computes them at 200,000. The houſes fronting the ſtreets, which are generally broad, are very indifferent; but towards the gardens they preſent a handſome appearance. The market-places are well conſtructed, and ornamented with a rich colonade of variegated marble. The city is divided into 23 diſtricts, each under its diſtinct magiſtrate: that allotted to the Chriſtians is mean, and much inferior to the other parts of the town. The greater part of the inhabitants conſiſts of Arabs and Turks; the number of Chriſtians is eſtimated at above 15,000, two-thirds of whom, ſays Volney, are ſchiſmatics. The Turks never ſpeak of the people of Damaſcus, without obſerving that they are the moſt miſchievous in the whole empire; and the Arabs have this proverb, "Shami, ſhoumi," the man of Damaſcus, wicked. Such is the prejudice ariſing from difference of religion, that the Chriſtians are generally hated by the fanatic and inſolent Mahometans, and repreſented as more vile and knaviſh than they are any where elſe. Accordingly they have been accuſtomed to deteſt the Franks, ſo that it is not poſſible to appear at Damaſcus in an European dreſs. This malignant ſpirit, however, is of late ſomewhat meliorated. The hatred which the people of Damaſcus bear to the Chriſtians is maintained and increaſed by their communication with Mecca. Their city, they ſay, is a holy place, ſince it is one of the gates of the Caaba; for Damaſcus is the rendezvous for all the pilgrims from the north of Aſia, as Cairo is for thoſe from Africa. This circumſtance has given to Damaſcus the title of "Mahomet's heel." See CARAVAN. Hence Damaſcus is the ſeat of a conſiderable trade; and its manufactures afford ſupport to a great number of Mahometans and Chriſtians: theſe conſiſt of ſilk and cotton, mixed or ſeparate, but chiefly mingled together, in the form of what they call *cottoni* or *alléja*. The former requires 125 drams of ſilk; and the latter is lighter, and compoſed of half the quantity. Much ſoap is alſo fabricated at Damaſcus, and carried from hence to other parts of Syria and to Egypt.

In the manufacture of ſoap, they uſe oil of olives, putting to an hundred weight 25 pounds of kali, and 5 pounds of pulverized chalk. The latter articles are boiled till the water be ſufficiently impregnated; the oil is then poured in; and the whole boils for three days over a fire compoſed of ſtones of olives. Such of the European articles as are uſed by the orientals are drawn from Seidé, Beirût, and Tripoli, to and from all which places, there are regular caravans, iron, lead, tin, cochineal, broad-cloth. From Perſia and the Eaſt, the caravans of Bagdad convey ſhawls, muſlins, and the rich fabrics of Surat, a part of which is conſumed in the city, and a part paſſes on to other places in Syria, and to European Turkey. To maritime commerce the Damaſcenes were formerly very adverſe; and it is only within theſe few years that they could be prevailed on to ſend goods by ſea to Conſtantinople. The population and commerce of Damaſcus are on the increaſe, in conſequence of the juſtice and equity of the preſent pacha or baſhaw, Abdallah. The rent of houſes, though low, is ſenſibly increaſing by reaſon of the influx of ſtrangers, and the ſuburbs are ſpreading by new buildings. For an account of the ancient DAMASCUS *ſteel*, ſee that article.

A ſtriking contraſt is obſerved to exiſt between the inhabitants of Damaſcus and thoſe of Aleppo. The latter are vain and ſeditious; the former, on the contrary, ſober, induſtrious, and unoſtentatious. The females and children have commonly regular features and a fair complexion; the dreſs of the women is nearly the ſame as at Conſtantinople, *viz.* white muſlin veils, except the proſtitutes, who, as uſual all over the Eaſt, expoſe their faces. The charitable eſtabliſhments in Damaſcus are numerous; among which may be noted that conſtructed by ſultan Selim for the reception of ſtrangers; though his munificence has been ſince diverted into other channels. The building conſiſts of a very large quadrangle, lined with a colonade. It is entirely roofed in ſmall domes, covered with lead. The moſque is grand; the entrance ſupported by four large columns of red granite: it is covered with a cupola, and has two minarets. Adjacent to it is a large garden. The apartments are numerous; and the whole eſtabliſhment grand and magnificent.

The large ſquare courts of the city are beautified with fragrant trees, and marble fountains, and compaſſed round with ſplendid apartments. In theſe apartments the ceilings and traves are uſually painted and gilded; and their duans, which are a ſort of low ſtages, ſituated in the pleaſanteſt part of the room, elevated about 16 or 18 inches above the floor, on which the Turks eat, ſleep, ſmoke, receive viſits, ſay their prayers, &c. are adorned on the ſides with a variety of marble mixed in Moſaic knots and mazes, ſpread with carpets, and furniſhed all round with bolſters and cuſhions in the very higheſt degree of luxury. In this city, ſays Maundrell, is ſhewn the church of John the Baptiſt, now converted into a famous moſque; the houſe of Ananias, which is only a ſmall grotto, or cellar; and the houſe of Judas, with whom St. Paul lodged, in which is an old tomb, ſuppoſed to be the burying place of Ananias, which is held in ſuch veneration, that a lamp is continually burning over it. To this account we may add, that the fruit-tree called the Damaſcene, and the flower called the damaſk-roſe, were tranſplanted from the gardens belonging to this city; and that the ſilks and linen, known by the name of damaſks, were, probably, the invention of its inhabitants. Volney's Travels in Egypt and Syria, vol. ii. De Pages's Travels, vol. ii. Browne's Travels in Africa, p. 396, &c.

DAMASCUS, *Pachalic of*, is one of the four pachalics of Syria, comprehending nearly the whole eaſtern part of that country. It extends to the north from Marra on the road to Aleppo, as far as Hebroun or Hebron, in the ſouth-eaſt part of Paleſtine. It is bounded to the weſt by the moun-

tains

tains of the Anſarians, thoſe of Anti-Lebanon, and the upper part of the Jordan; then croſſing that river in the country of Biſan, it includes Nablous, Jeruſalem, and Hebroun, and enters the deſert to the eaſt, into which it advances more or leſs, as the country is capable of cultivation; but in general it does not extend to any conſiderable diſtance from the latter mountains, except where it approaches Tadmor or Palmyra, towards which it ſtretches full five days' journey. In this vaſt extent of country, the ſoil and its productions are very various; but the plains of the Hauran, and thoſe on the banks of the Orontes, are the moſt fertile; they produce wheat, barley, doura or durra, ſeſamum, and cotton. The ſoil of the country of Damaſcus, and the Upper Bekaa, is gravelly and poor, better adapted to fruits and tobacco than to any thing elſe. On the mountains are cultivated, olive, mulberry, and fruit trees, and in ſome places vines, from which the Greeks make wine, and the Mahometans dried raiſins. The pacha enjoys privileges more conſiderable than thoſe of any other pachalic; for beſides the farm of all the cuſtoms and impoſts, and an abſolute authority, he is alſo conductor of the ſacred caravan of Mecca, under the highly reſpected title of "Emir Hadj." The Mahometans regard this office with ſuch reverence, that a pacha, who acquits himſelf well in it, becomes inviolable even by the ſultan, nor is it permitted to ſhed his blood. But the divan has contrived to ſatisfy his vengeance, without infringing this privilege, by ordering thoſe who incur his diſpleaſure to be pounded in a mortar, or ſmothered in a ſack, of which there have been various inſtances. The tribute of the pacha to the ſultan is no more than 45 purſes, *i. e.* 2343 *l.*; but he is charged with all the expences of the Hodj, eſtimated at 6000 purſes, or 312,500 *l.* They conſiſt of proviſions of corn, barley, rice, &c. and the hire of camels, which muſt be provided for the eſcort, and a great number of pilgrims. Beſides this, 800 purſes muſt be paid to the Arab tribes, who dwell near the road, to ſecure a free paſſage. The pacha reimburſes himſelf by the miri, or duty upon lands, either by collecting it himſelf, or farming it out. The pacha is alſo heir of all the pilgrims who die on the journey; and, beſides, he has the profits from lending money upon intereſt to merchants and farmers, and taking from them whatever he thinks proper in the way of *baſſe* or extortion. His military eſtabliſhment conſiſts of 6 or 700 janizaries, as many Barbary Arabs, who are naked and plunderers, and 8 or 900 dellibaſhes, or horſemen. Theſe ſerve as an eſcort for the caravan, and for reſtraining the Arabs, and likewiſe to enable him to collect the miri from his own ſubjects. The pachalic of Damaſcus, though more expoſed than any other to the incurſions of the Bedouin Arabs, is the leaſt ravaged of any in Syria: and the reaſon is, that this pachalic is uſually held for life. Volney's Travels, vol. ii.

DAMASCUS *ſteel*, a very fine kind of ſteel, made in ſome parts of the Levant, and particularly at Damaſcus, remarkable for its excellent temper; and uſed chiefly in the making of ſword blades.

Some authors aſſure us it comes from the kingdom of Golconda in the Eaſt Indies; where the method of tempering with alum, which the Europeans have never been able to imitate, was firſt invented.

About the beginning of the 14th century, Timûr Leng, on his conqueſt of Syria, conveyed all the celebrated manufactures of ſteel from Damaſcus into Perſia. Since that period, its works in ſteel have been little memorable. They were formerly of the higheſt reputation in Europe and the Eaſt. The famous ſabres appear to have been conſtructed by a method now loſt, of alternate layers, about two or three lines thick, of iron and ſteel: they never broke, though bent in the moſt violent manner, and yet retained the utmoſt power of edge, ſo that common irons or even ſteel, would divide, under their force.

DAMASENSA, in *Geography*, a town of Africa, in the country of Jagra, ſituated on a river of the ſame name, which runs into the river Gambia.

DAMASI MONTES, or DOBASSI MONTES, in *Ancient Geography*, mountains of India, which, according to Ptolemy, extended along the 32d or 33d degree of latitude. It is thought that they were the mountains which bounded the eſtates of the Great Mogul and thoſe of the king of Ava to the north.

DAMASK, French *Damas*, in the *Manufacture of Cloth*, is a tweeled fabric, with flowers, or other ornaments, raiſed upon it, generally of very extenſive patterns.

It has been conjectured, from the ſimilarity of the name, that this branch of the art of weaving originated at Damaſcus. Whether this etymology be correct or not, damaſk has been long woven in ſilk, both in France and Italy. We find in many of our own popular ballads and legends, that a damaſk gown or bed is frequently noticed as an article of magnificence.

The damaſk manufacture of the continent was chiefly of ſilk for garments and ornamental furniture, ſuch as bed-hangings, table-linen, and the like. The ſilk damaſk was frequently woven with a great variety of colours, and produced a very beautiful effect. It is not exactly aſcertained at what period the art of weaving this ſpecies of cloth was introduced into Britain; but it is probable that it was brought over in queen Elizabeth's reign, by the Dutch and Flemiſh weavers, who fled from the perſecutions of the duke of Alva, and his maſter Philip II. of Spain. The ſilk damaſk, from the high price of the raw material, and the great labour of mounting and working the looms, was very expenſive, and, among the middling ranks of people, articles of this kind were only worn upon occaſions of ceremony, and at all other times carefully preſerved, and frequently tranſmitted for ſeveral ſucceſſive generations in the ſame family. The more modern practice of purchaſing articles of dreſs at moderate rates, and changing them frequently according to the variations of taſte or faſhion, has almoſt entirely exploded the uſe of ſilk damaſk, at leaſt in Britain. This branch of ornamental manufacture is now almoſt entirely confined to the fabrication of table-linen, which is manufactured to great extent, and in great variety. The chief ſeat of this manufacture is probably the town and neighbourhood of Dunfermline, in Fifeſhire, where it is conſidered as the ſtaple, and has proved a very profitable branch of traffic to the manufacturer, and given employment to many induſtrious people.

The material uſed there is chiefly linen; but many have been recently woven of cotton, ſince the introduction of that article into the manufacture of cloth has become ſo prevalent. The cotton damaſks are conſiderably cheaper than thoſe of linen; but are not conſidered either ſo elegant or durable. The cotton, alſo, unleſs frequently bleached, does not preſerve the purity of the white colour nearly ſo well as the linen.

The tweeling of the more common kinds of damaſk is generally performed with five leaves of front mounting, excluſive of the harneſs of the draw loom. The fineſt and moſt extenſively ornamented damaſks are woven with eight leaves. The patterns of the damaſk, which are frequently very extenſive, are called *deſigns*, and are drawn upon paper lined into ſmall ſquares to direct the weaver in mounting his loom, ſo as to produce the deſign required.

For

For a particular deſcription of the proceſs of manufacturing damaſk, ſee the articles DESIGN, and DRAW-LOOM.

DAMASKEENING, the art, or act, of adorning iron, ſteel, &c. by making inciſions therein, and filling them up with gold or ſilver wire; chiefly uſed in enriching ſword-blades, guards and gripes, locks of piſtols, &c.

Its name ſhews the place of its origin, or, at leaſt, the place where it has been practiſed in the greateſt perfection, *viz.* the city of Damaſcus in Syria; though M. Felibien attributes the perfection of the art to his countryman Curſinet, who wrought under the reign of king Henry IV.

Damaſkeening is partly moſaic work, partly engraving, and partly carving; as moſaic work it conſiſts of pieces inlaid; as engraving, the metal is indented, or cut in creux; and as carving, gold and ſilver are wrought therein in *relievo*.

There are two ways of damaſkeening; in the firſt, which is the moſt beautiful, the artiſts cut into the metal with a graver, and other tools proper for engraving on ſteel; and afterwards fill up the inciſions, or notches, with a pretty thick ſilver or gold wire. In the other, which is only ſuperficial, they content themſelves to make hatches, or ſtrokes acroſs the iron, &c. with a cutting-knife, ſuch as is uſed in making of ſmall files. As to the firſt, it is neceſſary the gravings, or inciſions, be made in the dove-tail form; that the gold or ſilver wire, which is thruſt forcibly into them, may adhere the more ſtrongly. As to the ſecond, which is the more uſual, the method is this: having heated the ſteel till it changes to a violet, or blue colour, they hatch it over and acroſs with the knife; then draw the enſign, or ornament, intended, on this hatching, with a fine braſs point, or bodkin. This done, they take fine gold wire, and conducting or chaſing it according to the figures already deſigned, they ſink it carefully into the hatches of the metal with a copper tool.

DAMASONIUM, in *Botany*. See ALISMA and STRATIOTES.

DAMASQUITTE, a kind of ſtuff made at Venice, of which there are two ſorts; one with gold, the other with ſilk; the pieces are eighteen ells long.

DAMASSIN, a kind of damaſk, with gold and ſilver flowers, made in warp and woof, or wrought, and not raw ſilk.

DAMASUS I., POPE, in *Biography*, ſuppoſed to be a Spaniard by birth, obtained the high rank of biſhop of Rome in the year 366. In competition for this office he had for a rival Urſinus, to whom a large body of the people and clergy was attached. The conteſt on this occaſion involved the city in a civil war, in which much miſchief was done, and much cruelty perpetrated. Both were proclaimed lawful biſhops, and ſucceſſors to St. Peter at the ſame time; each was, however, too jealous of his rival to admit the poſſibility of a two-fold power. Damaſus at length proved triumphant; Urſinus and his adherents were baniſhed, having firſt ſuffered the penalties of impriſonment and confiſcation. Damaſus was more attached to the pomp, parade, and luxury of the temporal ſtate, than to the decorum and diſcipline which he owed to his rank as biſhop of ſouls. He ſeemed to be totally regardleſs of the morals of the people entruſted to his care; but againſt hereſy, as it was called, he diſplayed the vigilance and zeal of a bitter perſecutor. In five different councils held at Rome between the years 368 and 381, he procured decrees againſt the Arians, and other ſects who had departed from the eſtabliſhed faith; and prevailed on the imperial court to enact penal laws againſt them, which were executed with the utmoſt rigour. Damaſus extended the power and authority of the biſhops of Rome, and laid the foundation of the cuſtom of conferring upon certain biſhops the title of vicars to the pope, by which they were enabled to perform ſeveral authoritative acts, which they could not by the mere virtue of epiſcopal power: hence the rights of biſhops and ſynods became gradually and entirely dependent on the authority of the pope. Damaſus died at Rome in the year 384. His works are partly in proſe, and partly in verſe; they were printed at Rome in 1639, and at Paris in 1672, but they ſeem to have little claim to any ſpecific notice. They are treated of at large by Moreri, to whom we refer for a further account.

DAMASUS II., *Pope*, in the eleventh century, was a native of Bavaria. He is repreſented to have been a perſon of learning, and exemplary piety. He was poſſeſſor of the biſhoprics of Brixen and Aquileia in ſucceſſion, before he attained to the ſee of Rome, which happened upon the death of Clement II. To this dignity he was raiſed by the emperor Henry III., who ſent him to Rome to maintain the imperial right of nomination to the popedom, in oppoſition to the claims of Benedict IX., who had ſeized on it, but who quitted his pretenſions in favour of one who had ſo powerful a protector. Damaſus enjoyed his office only a few days, dying at Preneſte in 1048, ſuppoſed to have been poiſoned. Moreri.

DAMATCORENSIS, in *Ancient Geography*, an epiſcopal city of Proconſular Africa.

DAMATER, or DEMETER, in *Mythology*, the ſurname of Ceres. Vocabatur Ceres, Δημητης, quaſi Γημητης. *i. e.* Terra mater. Serv. in Virgil Æneid. iii. She derived this name from her having firſt taught men the art of cultivating the earth.

DAMATRIUS, in *Ancient Chronology*, the Bœotian name of the Athenian month *Pyanepſion*, which was the fifth of their year, and correſponded to the latter part of our October and beginning of November. See PYANEPSION and MONTH.

DAMAZAN, in *Geography*. See DAMASAN.

DAMBACH, a town of France, in the department of the Lower Rhine; 6½ leagues S.S.E. of Straſburg.—Alſo, a town of Germany, in the arch-duchy of Auſtria; 8 miles E.S.E. of Freuſtadt.

DAMBANNA, a town of Africa, in the kingdom of Kontu.

DAMBEK, or DAMKE, a town of Germany, in the circle of Upper Saxony, and Old Mark of Brandenburg; 4 miles S. of Saltwedel.

DAMBI, a country of Africa, in the kingdom of Kongo, which, together with other inferior provinces, followed the example of the duchy of Ovando, and ſhook off the yoke of the kings of Kongo, to put themſelves under the protection of the Portugueſe, induced by the hopes, and perhaps the promiſes of being leſs oppreſſed, and of enjoying greater liberty under theſe than they did under their own monarchs.

DAMBLAIN, a town of France, in the department of the Voſges and diſtrict of La Marche; 5 miles E. of La Marche.

DAMBROUCZA, a town of Poland, in the palatinate of Lemberg; 8 miles N.E. of Lemberg.

DAME was formerly a title of honour, and is ſtill uſed in the Engliſh law to denote a lady; but in common acceptation it ſignifies the miſtreſs of a family of the lower rank in the country.

DAME, (from *domna*, the abbreviation of *Domina,*) the title of nuns of the Benedictine and certain other ancient orders. See DOMNUS and NUN.

DAME'S-*Violet*. See HESPERIS.

DAMEL, or KAYO, in *Geography*, a country of Africa, on the coaſt of the Atlantic, between the rivers Senegal and Gambia.

DAMELEN, a town of Germany, in the circle of Upper Saxony, and Middle Mark of Brandenburg; 6 miles W. of Belitz.

DAMELOFRE, a kind of bilander uſed in Holland, for conveying merchandize from one canal to another, and contrived for commodious paſſage under the bridges.

DAMENSII, in *Ancient Geography*, a people of Africa, occupying the interior of the region called Syrtica.

DAMERAUCOUR, in *Geography*, a ſmall town of France, in the department of the Somme, 6 miles S. of Foix.

DAMERISCOTTA *Bay*, *River*, and *Pond*, in America, in the ſtate of Maine. The *bay* communicates with Townſend harbour, or Booth-bay; the *river*, which is navigable 15 miles, and on which are ſeveral mills, is ſhort, is parallel with Sheepſcot river, E. of it, divides the town of Booth-bay from Briſtol, and riſes in Dameriſcotta *pond*, which is about 10 miles long and 2 wide, and ſpreads between Newcaſtle and Waldoborough.

DAMERSHEIM, a town of Germany, in the circle of Bavaria, and principality of Neuburg; 10 miles N.W. of Neuburg.

DAMERY, a ſmall town of France in the department of the Marne, between Ay and Chatillon on the river Marne, 3 miles W. of Epernay, remarkable for its excellent red Champaign, known by the name of Oeil de Perdrix.

DAMGARTEN, or DAMGARD, and anciently *Damgur*, *Damgor*, *Damagora*, a ſmall town of Germany, in that part of Pomerania, which, having belonged to Sweden, is at preſent in poſſeſſion of the French. It is ſituated on an eminence not far from the river Reckenitz, 21 miles W. of Stralſund. N. lat. 54° 20′.

DAMIA, in *Mythology*, a pagan divinity, or the good goddeſs, ſaid by Varro to be the wife of Faunus, and by Macrobius to be Cybele, and ſo chaſte, that ſhe never ſaw nor heard any other man than her own huſband. Her ſacrifice, which was privately offered on the firſt day of May, in houſes, having their doors and windows ſhut, was called Damium. No man, nor picture of a male, was ſuffered to be preſent, nor woman to reveal what paſſed. They ſpent nights and days in this feſtival, magnificently apparelled; danced, ſung, and took what liberties they pleaſed. Δαμιον, it is ſaid, is a word of the Doric dialect, and is put for δημιον, *i.e.* δημοδιον. *public*. Some have taken this expreſſion for an antiphraſis, as if it ſignified that nothing was leſs public than this feſtival; but we learn from Cicero, (Haruſp. Reſp. c. 17.) that this ſacrifice was offered to the good goddeſs for the public. Cicero ſays, that the places appointed for this ſolemnity were the houſes of the firſt magiſtrates, and that this privilege belonged to the conſuls and prieſts only.

DAMIAN, ST., in *Geography*, a ſmall town of France in the department of the Sture, which formerly was a part of Piedmont in Italy. It contains 1498 inhabitants, and is the chief place of a canton in the diſtrict of Coni. The canton itſelf has 14 communes, with a population of 11,276 individuals.

DAMIANA, or DAMINA, in *Ancient Geography*, a town of Spain, in the country of the Edetani.

DAMIANI, in *Biography*, an opera ſinger, with a *ſoprano* voice, of conſiderable merit. His voice is ſweet and flexible, but not powerful. His taſte modern, but his fancy not very fertile in cadences and embelliſhments. He came to England, in 1800, to ſing at the Haymarket, but from ſome difference between him and the manager, he tore his article and threw it in the fire, and only performed at a concert eſtabliſhed on the merit of his talents by the worthy Raimondi, on a ſuppoſition that the public not being able to hear him at the opera, would be curious, and eagerly ſubſcribe to a concert where he was to perform, but though a good ſinger, his talents and fame were not of that tranſcendent kind which incline lovers of muſic to think it neceſſary to hear him in order to qualify themſelves for converſation; and Damiani, who was highly paid for his performance, though he increaſed his fortune by the engagement, did not augment his fame.

DAMIANISTS, in *Eccleſiaſtical Hiſtory*, a branch of the ancient Acephalous Severites; who agreed with the Catholics in admitting the fourth council; but diſowned any diſtinction of perſons in the Godhead, and profeſſed one ſingle nature incapable of any difference; and yet they called God, the Father, Son, and Holy Ghoſt. On which account the Severitæ Petritæ, another branch of Acephali, uſed to call them Sabellianiſts, and ſometimes Tetraditæ. Thus much we learn from Nicephorus Calliſtus, lib. xviii. cap. 49.

They took their name from *Damianus*, a biſhop of Alexandria, who was originally their leader, in the ſixth century.

DAMIANO, PETER, in *Biography*, was born at Ravenna in the beginning of the eleventh century. His deſcent was highly reſpectable, and he enjoyed the advantages of a good education, which he improved with ſo much diligence, as to render himſelf capable of offices of diſtinguiſhed truſt, and importance. In the year 1057 he was created cardinal, by pope Stephen IX. much againſt his own wiſhes, which led him, it is ſaid, to prefer a private and a ſtudious life to public honours. If he really deſired privacy, he was unfortunate in being appointed to ſeveral good livings and appointments in the church. Under the pontificate of Nicholas II. he was ſent papal legate to Milan, to reform the clerical abuſes in that dioceſe, and for other objects of ſtate policy. Theſe duties he performed to the ſatisfaction of his employers. Upon his return to Rome he became diſguſted with the profligacy of manners which prevailed among all ranks of the people, and with a becoming zeal for the intereſts of religion, expoſtulated againſt the ambitious interference of the pontiffs in the temporal concerns of princes, the univerſal relaxation of order and diſcipline, and the enormous vices practiſed by the monks and clergy. Finding that his remonſtrances produced no good effect, he reſolved to withdraw from a ſociety, whoſe manners he in vain attempted to reform; and having reſigned his ſeveral preferments into the hands of pope Alexander II., he retired to a monaſtery in 1061. Here he was not permitted to remain; his integrity and ability rendered him fit for ſervices of active life, and he was ſent, in 1062, papal legate to France. In the following years he was ſent on miſſions to Florence, and different parts of Germany. He died in the year 1073, highly reſpected by his contemporaries; his works, which were numerous, entitle him to be ranked among the beſt writers of the times in which he flouriſhed.

DAMIANO, *Saint*, in *Geography*, a ſmall town of France, in the department of the Tanaro, which formerly was a part of Piedmont in Italy. It is the chief place of a canton, in the diſtrict of Aſti, 9 miles N. of Alba, and has a population of 6109 individuals. The canton contains 5 communes and 11,347 inhabitants.

DAMIANOVITZ, a town of Croatia, 64 miles S. of Varaſdin, and 52 E. S. E. of Carlſtadt.

DAMIATTE, a ſmall town of France, in the department of the Tarn, 12 miles W. of Caſtres.

DAMICOTTA, a town of Hindooſtan, in the Coimbetore country; 30 miles N. of Coimbetore, and 60 S. of Seringapatam. N. lat. 11° 28′. E. long. 41° 25′.

DAMIER, in *Conchyliology*, the name given by French naturaliſts

naturaliſts to that elegant ſpecies of voluta, the ſpots of which ſtand in a checquered order, and reſemble the marks of a draught or cheſs board, that being the common ſignification of the word *damier*. See VOLUTA.

DAMIETTA, or DAMIATT, in *Geography*, a ſea-port town of Egypt, which forms a vaſt creſcent at the mouth of the eaſtern branch of the Nile. Steph. Byz. informs us that, under the government of the Greeks of the lower empire, it was called "Thamiatis," and that it was then very inconſiderable. But in proportion as Peluſium declined, it acquired increaſing importance; and at length the total ruin of this ancient town occaſioned the commerce of the eaſtern ports of the Delta to be transferred to Damietta. When the emperors of Conſtantinople took poſſeſſion of it a ſecond time, about the year 238 of the Hegira, A. D. 852, the caliphs perceived the importance of a harbour ſo favourably ſituated; and in the year of the Hegira 244, A. D. 858, the emperor Elmetouakkel ſurrounded it with ſtrong walls. Notwithſtanding this defence, Roger, king of Sicily, took it from the Mahometans in the year of the Hegira 550, A. D. 1155; but ſoon after Salah Eddin, who mounted the throne of Egypt, expelled the Europeans from this city; and when they returned to beſiege it, about 15 years after, this able ſultan baffled all their efforts, and obliged them to retreat, though their land army was ſupported by a fleet of 1200 ſail. In the year 615 of the Hegira, A. D. 1218, under the reign of Eladel, the cruſaders attacked it with a conſiderable force; and having carried by ſtorm the tower on the weſtern ſhore of the Nile, where they had encamped, and broken the ſtrong iron chain, which reached from one ſide to the other, they opened the entrance of the river for their fleet. Nejm Eddin, the ſultan's ſon, made a vigorous reſiſtance, threw a bridge over the river, which the Franks demoliſhed, and choaked up the mouth of the river, which he rendered almoſt impaſſable, by ſinking ſeveral large boats. After alternate ſucceſſes and defeats, many bloody conflicts, and a ſiege of 17 months, the Chriſtian princes took Damietta by ſtorm. However, their tenure was of ſhort duration; for being completely inveſted near the canal of Achmoun, $\frac{1}{4}$ of a league N. of Manſoura, where St. Lewis finiſhed his exploits, by the waters of the Nile and by the Egyptian army, they purchaſed their lives and liberty by the ſurrender of their conqueſt. Thirty-one years after this defeat, St. Lewis carried Damietta without ſtriking a ſtroke. Having thrown himſelf into the waves, in complete armour, to march upon the enemy intrenched upon its banks, he thus ſtruck a panic into their army, ſo that they took flight, and ſhamefully abandoned a fortreſs filled with ſlaves, and capable of a long reſiſtance. The Arabs ſoon recovered it, but tired of defending it, they totally deſtroyed it, and rebuilt it further up in the country. "Damietta being deſtroyed, (ſays Abulfeda) a ſmall town was built at ſome diſtance, called *Menchié*, which is become a conſiderable place. In our days (100 years after its foundation) we ſee ſeveral ſquares, market-places, and public baths. The aneient city was razed to the ground in the year 648 of the Hegira," (A. D. 1250); or, as ſome Arabian hiſtorians ſay, 4 years before this epocha. "The caliph Elmetouakkel, of the family of the Abaſſides, built the walls. The misfortunes it had occaſioned to the Mahometans, and the wars to which it had given riſe, drove them to that extremity. It ſeemed, in fact, as if this fortreſs, in a peculiar manner, invited the Franks, who alternately laid ſiege to the walls." When the French threatened Egypt a ſecond time, it was reſolved to deſtroy Damietta; and it was ſo completely razed to the ground, that there remained no veſtige of it, except the great moſque. Its ruins are diſcernible at the village of Eſbé, on the eaſtern bank of the Nile, a ſhort league from the ſea, which diſtance has been gained by the Delta in the courſe of 600 years. Eleven years after this time the mouth of the Nile was choked up by a bar, which is called Bogaz, ſo as to prevent the enemy's fleets from getting up the river, and to render acceſs as dangerous as that of Roſetta. It is now impaſſable, even for boats, during ſeveral months of the year, and ſhipwrecks frequently occur here. From this epocha its entrance is prohibited to all veſſels, which are now obliged to anchor in the road. The town of Damietta, now ſubſiſting, was built after the deſtruction of the ancient city; and it is ſituated a little above it on the ſame ſide, or about $1\frac{1}{2}$ league diſtant from the village of Eſbé, where the traces of the former are diſcoverable. The modern Damietta, firſt called *Menchié*, as Abulfeda tells us, has preſerved the memory of its origin in a ſquare ſtill called by that name. Writers in general have confounded theſe two towns, and aſcribed to the one the attributes of the other. This is the caſe with father Sicard, Pocock, Proſper Alpinus, Maillet, Shaw, and even Niebuhr. The towers, which have led writers to take the modern for the ancient Damietta, were built by the Mamelukes for the defence of the new town. As they were uſeleſs, they have demoliſhed one, and employed its materials in the conſtruction of a ſmall fort, which is at the mouth of the river. This place, ſays Savary, who paſſed 14 months in it, is large, and not leſs agreeable, than Roſetta, is rounded in a ſemicircle on the eaſtern bank of the Nile, $2\frac{1}{2}$ leagues from the mouth of it. The eye, placed at one of the extremities of the creſcent, takes in its whole extent. It is reckoned to contain 80,000 inhabitants. It has ſeveral ſquares, the moſt conſiderable of which has retained the name of *Menchié*. The bazars are filled with merchants. "Okals" or "khans," as ſpacious as thoſe of Boulak, collecting under their porticos the ſtuffs of India, the ſilks of mount Lebanon, ſal ammoniac, and pyramids of rice, proclaim that it is a commercial town. The houſes, eſpecially thoſe on the banks of the river, are very lofty. They have, in general, handſome ſaloons built on the tops of their terraces, which are cheerful belvideres, open to every wind, where the Turk, effeminately reclining on a ſopha, paſſes his life in ſmoking, in looking on the ſea, which bounds the horizon on one ſide, on the great lake that extends itſelf on the other, and on the Nile, which, running between them, traverſes a rich country. Several large moſques, adorned with lofty minarets, are diſperſed over the town. The public baths, lined with marble, are diſtributed in the ſame manner as thoſe of Grand Cairo. The linen with which you are ſerved is clean, and the water very pure. The heat, and the treatment in them, ſo far from injuring the health, ſerve to ſtrengthen, and even to improve it, if uſed with moderation.

The port of Damietta is continually filled with a multitude of boats and ſmall veſſels. Theſe called "Scherm" ſerve to convey the merchandize on board the ſhips in the road, and to unload them: the others carry on the coaſting trade. This town carries on a great trade with Syria, Cyprus, and Marſeilles. The rice, called "Mezelaoui," of the fineſt quality in Egypt, is cultivated in the neighbouring plains. The exports of it, ſays Savary, amount annually to about 6 millions of livres. The other articles of the produce of the country are linens, ſal ammoniac, corn, &c. A ruinous policy for the country prohibits the exportation of this laſt article; but the law is evaded, and it paſſes under the name of rice. The Chriſtians of Aleppo and Damaſcus, ſettled in this town, have for ſeveral ages

carried on its principal commerce. No Chriſtian merchant, or European, muſt, ſays Niebuhr, reſide here; although there be in Damietta a conſiderable number of Maronites and Armenians, who communicate with the church of Rome. A conſul, and French merchants, once reſided at Damietta. But the inhabitants, obſerving that theſe ſtrangers made too free with their women, roſe up in a fury, and maſſacred them all. Since that period the king of France forbade his ſubjects not only to ſettle in this city, but even to frequent it. The inhabitants of Damietta are generally reckoned more unfriendly to the Chriſtians than any of the other inhabitants of Egypt. The memory of the Cruſades, perhaps, keeps up this inveterate averſion. In the neighbourhood of this city are many rice fields: but towards the ſhore, the ground is covered with ſand, and conſequently barren. As the Bogaz prevents ſhips from entering the Nile, their cargoes are conveyed on board by the boats of the country; and this circumſtance affords opportunity for much fraud and diſſenſion. The badneſs of the port of Damietta is ſtill more detrimental to the commerce of the city. The road where the veſſels lie being expoſed to every wind, the ſlighteſt gale obliges the captains to cut their cables, and take ſhelter at Cyprus, or to ſtand off to ſea. But did not the indolence and deſpotiſm of the Turks prevent it, it would be eaſy, by cutting a canal of half a league, to open a paſſage for ſhips into the Nile, where there is deep water; and thus Damietta would be rendered a noble harbour.

The tongue of land on which Damietta is ſituated, ſtraightened on one ſide by the river, and on the other by the weſtern extremity of the lake Menzalê, is only from two to ſix miles wide from eaſt to weſt. It is interſected by innumerable rivulets in every direction, which render it the moſt fertile ſpot in Egypt. The ſoil produces, *communibus annis*, 80 buſhels of rice for one; the other produce is in the ſame proportion. Nature here preſents flowers, fruits, and harveſts, at every ſeaſon of the year. Winter never deprives it of theſe advantages; nor are its beauties ever impaired by ſummer. Deſtructive heats as well as chilling colds are equally unknown in this happy ſpot. The thermometer varies only from 9 to 24 degrees above the freezing point. Damietta is indebted for this charming temperature to the immenſe quantity of water, with which it is ſurrounded. The rivulets round the fields of rice are lined with ſeveral kinds of reeds, ſome of which riſe to a great height. The reed *Calamus* is here found in abundance, and is uſed for writing by the orientals. Here are alſo foreſts of papyrus, of which the ancient Egyptians made their paper: the lotus alſo, called by the Arabs nuphar, exalts its lofty ſtalk above the waters, and diffuſes from its flowers a moſt agreeable odour along the marſhes and canals in the interior parts of the country.

There are many villages round Damietta, in moſt of which are manufactures, where the moſt beautiful linens of the country are fabricated: and, in particular, the fineſt napkins, fringed with ſilk, are made here. Theſe ſmall towns, generally ſurrounded with little woods, or trees promiſcuouſly planted, form a pictureſque and whimſical aſſemblage. The elegant caſſia-tree, with its cluſters of yellow flowers, is ſeen by the ſide of the ſycamore and tamarind; the date-tree lifts its head with enormous branches above the grove: the orange and lemon-trees cover the labourer's cabin with their golden fruit; the banana-tree, the pomegranate, and the fig-tree, with their different productions, throw a vaſt variety into theſe landſcapes. At a mile from the town to the ſouth-weſt is a grove of orange-trees, which ſerves as a walk for the inhabitants: at the end of the walk is a canal filled with papyrus. Damietta is diſtant 84 miles N.N.E. from Cairo. N. lat. 31° 25′ 44″. E. long. 31° 49′ 45″. Savary's Letters on Egypt, vol. i. Niebuhr's Travels in Arabia, &c. vol. i.

DAMINI, Pietro, in *Biography*, a painter, born at Caſtelfranco, in the year 1591. At an early period he received inſtructions from Gio. Batiſta Novelli, the ſcholar of Jacopo Palma, and a good colouriſt; but being deſirous of making himſelf maſter, as well of the theory as the practical part of his art, he aſſiduouſly ſtudied ſuch prints and pictures as he could obtain acceſs to, and improved himſelf by reading the works of Lomazzo and Albert Durer. Such was his reputation, that at the age of 20, he was employed upon a public work at Padua, where he eſtabliſhed himſelf. Many of his works are to be found in that city as well as in Venice, Vicenza, and the place of his nativity. Singularly beautiful is the altar-picture of Beato Simone Stock, in the church of S. Maria, at Caſtelfranco, and another which is ſurrounded by 12 ſmall pictures of ſtories from the Old and New Teſtament, which are executed with extraordinary taſte.

Even in his ſhort life, this artiſt ſeveral times changed his manner, in the attempt to obtain the perfection of the art. Sometimes he appears to have copied nature as he found her; at other times, as in his fine picture of the crucifixion in the church del Santo at Padua, he aſpired to the repreſentation of ideal beauty. He was carried off by the plague, in 1631, at a period when ſuch high expectations were formed of him, that it was even thought by ſome he would have equalled the great Titian. Lanzi.

Damini, Giorgio, the brother of Pietro, was alſo a native of Caſtelfranco. He excelled in portrait and pictures of ſmall figures, and his reputation was increaſing, when, with his brother, he died of the plague in 1631, leaving a ſiſter, named Damina, who alſo painted portrait. Lanzi.

DAMINS, in *Geography*, a town of Switzerland, in the Grey League; 10 miles N.N.E. of Ilantz.

DAMISCHE Sea, a large lake of Germany, or expanſion of the Oder, in the circle of Upper Saxony, northward of the town of Damm; 8 miles long and about $1\frac{1}{2}$ wide.

DAMIUPOLIS, in *Ancient Geography*, a town ſituated in the environs of Sebaſtopolis.

DAMM, in *Geography*, a ſmall town of Pruſſia, in Pomerania, near the lake of the ſame name; 3 miles E. of Stettin. N. lat. 53° 4′.

DAMMA, in *Ancient Geography*, a town of Serica, placed by Ptolemy above Piada.

DAMMANA, a town of Aſia in Arachoſia. Ptolemy.

DAMMARIE, in *Geography*, a ſmall town of France in the deparment of Eure and Loire, 9 miles S. of Chartres.—Alſo, a ſmall town of France in the department of the Meuſe, diſtrict of Bar ſur Ornain, and canton of Ligny.

DAMMARTIN, in Latin, *Dominium Martini*, a ſmall town of France, in the department of Seine and Marne, chief place of a canton in the diſtrict of Meaux, 27 miles N.E. of Paris, and 15 N.W. of Meaux. It has 1918, and the canton 11,129 inhabitants, 23 communes, and a territorial extent of 220 kiliometres.

Dammartin *ſur Tevre*, a ſmall town of France in the department of the Marne, diſtrict of Sainte Menehould, with a population of 312 individuals. It is the chief place of a canton, which contains 27 communes and 8134 inhabitants, upon a territorial extent of 380 kiliometres.

DAMME. See Dam.

DAMMER, a town in Sileſia, in the principality of Oels; 4 miles S.E. of Militſch.

DAMMIM, or Daminim, in *Ancient Geography*, a town

of Paleſtine, in the tribe of Juda, between Socho and Azeca; mentioned in the book of Kings.

DAMNA, a town of Scythia, on the other ſide of the Imaus. Ptolemy.—Alſo, a town of Paleſtine, in the tribe of Zebulun, allotted to the Levites of this tribe, who were of the family of Merari, mentioned in the book of Joſhua, and alſo by Euſebius and Jerome.

DAMNA, in *Geography*, a town of Arabia Deſerta; 80 miles S. of Damaſcus.

DAMNATA TERRA, ſynonymous with CAPUT *Mortuum*, which ſee.

DAMNÆ, in *Ancient Geography*, a people of Aſia, placed by Ptolemy in Serica.

DAMNII, in *Ancient Geography*, one of the 22 Britiſh nations, which, according to Ptolemy, inhabited that part of Britain, that lay on the ſouth of the wall of Antoninus, between the Friths of Forth and Clyde. They were, according to Camden and Baxter, the ancient inhabitants of Clydeſdale, Renfrew, Lenox, and Stirlingſhire. Their name, ſometimes written Dumnii, might perhaps be derived from the Britiſh word *Dun*, which ſignifies a hill or mountain; a great part of their country being hilly or mountainous. This was one of thoſe Britiſh nations, formerly unknown to the Romans, which were diſcovered by Agricola, in the third year of his government when he penetrated to the river Tay. It was in the country of the Damnii that Agricola built thoſe forts, into which he put his army in winter for the preſervation of his conqueſts: as it was in the ſame country, and probably in the ſame tract, that the famous wall was built in the reign of Antoninus Pius, to protect the Roman territories from the incurſions of the Caledonians. On account of this wall, and the many forts and caſtles upon it, this country was more frequented by the Romans than any other to the north of Severus's wall; and more remains of that illuſtrious people have been diſcovered in it than in any other part of Scotland. Their towns were Colonia, Vanduara, Coria, or Curia, Alauna, Lindum and Victoria.

DAMNONII, DANMONII, *Dumnonii, Dunmani*, or *Domnii*, a people of Great Britain, who inhabited the S.W. parts of Britain; or that tract of country now called Cornwall and Devonſhire, and probably part of Somerſetſhire; bounded on the S. by the Britiſh ocean, on the W. by St. George's channel, on the N. by the Severn ſea, and on the E. by the country of the Durotriges. Some other Britiſh tribes were alſo ſeated within theſe limits, as the Coſſini and Oſtedamnii, which were probably particular claſſes of the Damnonii; and, according to Mr. Baxter, were the keepers of their flocks and herds. As the ſeveral tribes of the Damnonii ſubmitted without much reſiſtance to the Romans, and never joined in any revolt againſt them, theſe people were under no neceſſity of building many forts, or keeping many garriſons in their country. Hence it happens that few Roman antiquities have been found in that country, and that they are ſeldom mentioned by Roman writers. Ptolemy mentions a few places on the ſea-coaſts and in the inland parts of this diſtrict, which were known to, and frequented by the Romans. The moſt conſiderable of theſe places are the famous promontories of Bolerium and Ocripum, now the Land's-End and the Lizard, and the towns of Iſca Damnoniorum and Tamare, now Exeter and Saltaſh. As the Damnonii ſubmitted quietly to the Romans, they might be allowed to live without moleſtation under their own princes and laws. In the moſt perfect ſtate of the Roman government in Britain, the country of the Damnonii made a part of the province called Flavia Cæſarienſis, and was governed by the preſident of that province. After the departure of the Romans, kingly government was immediately revived amongſt the Damnonii in the perſon of Vortigern, who was perhaps deſcended from the race of their ancient princes, as his name ſignifies in the Britiſh language a chieftain, or the head of a family.

DAMO, in *Biography*, daughter of Pythagoras the philoſopher, flouriſhed about 500 years before the preſent era. She was one of the favourite diſciples of her father, and was initiated by him in the ſecrets of his philoſophy. To her the ancient ſage entruſted all his writings, when he felt himſelf approaching his latter end; enjoining her never to make them public: this command ſhe ſtrictly obeyed, though tempted by large offers at a time when ſhe was ſtruggling with the evils of poverty. She led a ſingle life, in obedience to her father's wiſhes, and exhorted other young women, whoſe education ſhe took charge of, to do the ſame. See PYTHAGORAS.

DAMON, a Pythagorean philoſopher, who flouriſhed about 400 years before Chriſt, and who is celebrated for the friendſhip that ſubſiſted between him and Pythias, a philoſopher of the ſame ſect. One of theſe friends was condemned to death by Dionyſius, king of Syracuſe. He wiſhed for a reſpite for a few days, and liberty to depart from priſon to ſettle his affairs, on condition that the other ſhould take his place, and ſuffer in his ſtead, provided the condemned perſon did not return. The morning of the fatal day was come, and the youth had not ſurrendered: the attachment and confidence of his ſurety were now reproached by thoſe about him; but he felt no anxiety on his own account; he was ſure his friend would not and could not violate his promiſe, and he was juſtified in his belief by the actual ſurrender of his friend at the appointed hour. Dionyſius, ſtruck with the magnanimity of the one, and the fidelity of the other, freely forgave the offender, and entreated that he might be admitted to the participation of ſuch ſincere and diſintereſted friendſhip.

DAMON, an ancient Grecian muſician. Muſic, in general, was in ſuch favour, and the ſtudy of it was thought ſo eſſential a part of education, at Athens, in the time of Pericles and Socrates, that Plato and Plutarch have thought it neceſſary to inform us of whom thoſe two great perſonages received inſtructions in that art. Damon, the Athenian, was the muſic maſter of both. The philoſopher calls him his friend, in a dialogue of Plato, where Nicias, one of the interlocutors, informs the company, that Socrates had recommended, as a muſic maſter to his ſon, Damon, the diſciple of Agathocles, who not only excelled in his own profeſſion, but poſſeſſed every quality that could be wiſhed in a man to whom the care of youth was to be confided.

Damon had chiefly cultivated that part of muſic, which concerns time or cadence; for which he is highly commended by Plato, who ſeems to have regarded rhythm as the moſt eſſential part of muſic, and that upon which the morals of a people depended, more than upon melody, or, as the ancients called it, harmony. He is alſo mentioned by Ariſtides Quintilianus, as having excelled in characterizing his melodies, by a judicious choice of ſuch ſounds and intervals as were beſt adapted to the effects he intended to produce.

Pericles, the moſt accompliſhed character in antiquity, was not only a conſummate judge, but a great encourager of all the arts. And in his life, writen by Plutarch, we are told that the muſes bore a principal ſhare in all the public ſpectacles with which he entertained the people. He not only regulated and augmented the poetical and muſical conteſts

at the Panathenæan feſtivals, but built the odeum, or muſic-room, in which poets and muſicians daily exerciſed themſelves in their art, and rehearſed new compoſitions, before they were exhibited in the theatre.

Damon, William, an Engliſh muſician, who flouriſhed in the reign of queen Elizabeth, and who ſeems to have been the firſt who compoſed parts to the old German melodies that were ſung by John Huſs, and the Bohemian brethren to the metrical pſalms. *Damon's* title to his publication is the following. "**The Pſalmes of** David **in Engliſh meter, with notes of foure partes ſet unto them by** Guilielmo Damon, **to the uſe of the godly Chriſtians, for recreating themſelves, inſtede of fond and unſeemely ballades**, 1579."

Theſe parts not being well received by the public, he publiſhed others in 1585, and dedicated them to the lord treaſurer, Burleigh. We are in poſſeſſion of a *Miſerere*, in five parts compoſed by William Damon; obtained from Dr. Pepuſch's collection, about the year 1746. The harmony is clear and good, and the ſubject extremely ſimple and uniform, the parts conſtantly ſing a tetracord in *motto contrario*: as $\begin{cases} G\ F\ E\ D. \\ A\ B\ C\ \sharp\ D \end{cases}$

DAMOT, in *Geography*, a province of Abyſſinia, on the S.E. of the kingdom of Gojam; bounded by the Temei on the eaſt, by the Gult on the weſt, by the Nile on the ſouth, and by the high mountains of Amid Amid on the north. It is about 40 miles in length from north to ſouth, and ſomewhat more than 20 in breadth from eaſt to weſt. But this whole peninſula, ſurrounded with the river, is called Gojam, in general terms, from a line drawn though the ſouth end of the lake to Miné, the paſſage of the Nile in the way to Narea. See Gojam.

DAMP, *adjective* (from the Dutch *dampe)*, denotes a perceptible degree of moiſture in any thing; ſuch as in damp air, damp walls, damp apartments, damp linen, &c. The methods of aſcertaining the actual exiſtence or degree of dampneſs in any thing, an examination of the effects which it is likely to produce, and the various ways of removing it, are the objects of philoſophy, of medicine, and of civil economy; but as thoſe objects will be particularly noticed in various other articles of this Cyclopedia, ſuch as *evaporation*, *miſts*, *fogs*, *hygrometry*, *dew*, &c.; we ſhall in this place only give a compendious and ſuperficial idea of the whole. Almoſt all natural bodies, excepting metallic ſubſtances, moſt hard ſtones, vitrifications, and a few more, contain at all times a certain quantity of water; yet they are conſidered as being dry, when that quantity of water is not more than that which the affinity of the particles of the bodies to water can retain. But ſhould that affinity (*viz.* that degree of attraction between the particles of thoſe bodies and water) be diminiſhed by any adequate cauſe, or ſhould the quantity of water exceed that which the peculiar affinity of each body can retain, then the bodies are ſaid to be damp, and they will appear to be ſo, either by the mere touch of the human hand, or by the indications of hygrometers, and other inſtruments. Thus, common atmoſpherical air always contains a quantity of water which is perfectly diſſolved in the air, and is retained by every particle of the latter, in virtue of their mutual attraction of affinity. But that affinity is diminiſhed by cold, and is increaſed by heat; therefore, if a quantity of air be cooled by any adequate means, its affinity to water will of courſe be diminiſhed, and part of the water it contained will be ſeparated; forming a vapour which in ſome meaſure affects the tranſparency of the air, and is ready to attach itſelf to any other body which may be preſented to it in a ſtate fit for the abſorption of vapour. The air in that ſtate is ſaid to be damp, and an hygrometer placed in it will ſhew it to be ſo, by its uſual movement towards moiſture.

On the other hand, if cold air, which appears to be damp from the indications of hygrometers, or from moiſtening ſalts, &c.; be rendered much hotter, its affinity to water will thereby be increaſed, and the appearances of dampneſs will vaniſh.

Beſides the above-mentioned affinity, there is another power which enables bodies of every kind to retain water: and this is a ſort of ſuperficial adheſion. (See Capillary *Attraction.*) It acts moſt powerfully when a given quantity of water is expoſed to the action of a proportionately great quantity of ſurface; hence, all porous bodies have the power of retaining water to a certain degree, and under certain circumſtances. Therefore, in a variety of bodies both thoſe powers contribute to retain water at the ſame time, and ſuch moſt probably is the caſe with air itſelf.

Sometimes bodies contain water proportionate to their degree of affinity, yet other bodies will rob them of a portion of that water; and ſuch is the caſe with dry fixed alkalies, or freſh quick-lime, which will ſeparate water from air apparently very dry. This, however, only proves that certain bodies have a greater affinity to water than air or certain other bodies have.

In certain circumſtances a greater quantity of moiſture is crowded upon bodies than they can retain; hence they feel damp. Thus, the air which lies contiguous to water generally contains more moiſture than the air which is more remote; but the latter by degrees abſorbs the ſuperfluous moiſture of the former, and thereby enables it to imbibe more of the vapours which riſe from the contiguous water; and thus the proceſs of evaporation goes on. But if the free circulation or communication of the air be interrupted, then the air which is confined over the water will hold a conſiderable quantity of ſuperfluous moiſture, and will thereby become damp. Now ſuch is the caſe with the air of caves, cellars, holds of ſhips, &c. when any water is contained in thoſe places. From the above ſtatement it evidently appears that heating and ventilation are the two moſt powerful means of removing dampneſs. The action of heat diminiſhes the attraction of ſolids to water, and increaſes the affinity between air and the ſame fluid. Ventilation, when the air is dryer than other bodies, removes dampneſs by diſſipating the moiſture through the atmoſphere.

From the reſult of all the experiments that have hitherto been inſtituted, it appears, that a cubic foot of air ſaturated with water, contains two grains of water at the temperature of 32° Fah. (*viz.* at the point of melting ice); it contains four grains at the temperature of 48°, ſix grains at the temperature of 60°, and eight grains at the temperature of 68°.

A remarkable circumſtance attends the mixture of aqueous vapour with air, which is, that air thus ſaturated with vapour is lighter than an equal bulk of dryer air; and this ariſes from the denſity of the vapour thus mixed, which is leſs than the denſity of the air, in the proportion of three to four, according to Sauſſure.

The explanation of ſeveral natural phenomena may be eaſily derived from the above-mentioned facts, attending, however, to other concomitant circumſtances. Thus, in a calm day, when the air is ſerene, a cold wind ſprings up from the north or from the eaſt, the cold air mixes with the warmer, their capacity for containing water is diminiſhed, a

hazineſs enſues, and the air becomes damp; yet ſometimes the cold air is dryer on account of particular circumſtances, and though a hazineſs may at firſt appear, a perfect tranſparency will be reſtored ſoon after.

It frequently happens, that the vapour which is ſeparated from the air by the action of cold, remains ſuſpended in the ſhape of a miſt or cloud; yet at other times it deſcends immediately, and attaches itſelf to terreſtrial bodies in the form of dew. But in theſe phenomena the action of electricity ſeems to be in great meaſure concerned. We ſhall have occaſion to examine the nature of thoſe phenomena more at large in other parts of this work.

The effects of damp air, damp clothing, and damp apartments, are variouſly modified by the climate, by the temperature, and by the cuſtoms of the inhabitants, of every particular country.

DAMP, *noun ſubſtantive*, (from the Saxon *damp*, a vapour or exhalation,) means a fog, or moiſt air, or moiſture; but it is principally uſed in the plural, *damps*, to denote certain noxious vapours or exhalations iſſuing from the earth.

Theſe exhalations frequently occur in mines, coal-pits, wells, and other ſuch like excavations; but ſometimes they are alſo to be met with near the ſurface of the earth, eſpecially in the vicinity of volcanoes. The noxious quality of ſuch exhalations, and the numerous fatal effects which they have produced, have obliged mankind to collect the various accounts of the phenomena, to inveſtigate their origin, and to contrive methods of preventing their dire effects. But the accounts have been moſtly furniſhed by miners, whoſe ignorance, whoſe fears, and whoſe ſufferings, have generally involved the truth in a conſiderable proportion of exaggeration; yet, from a careful compariſon of thoſe very accounts, from the reſult of experiments inſtituted by ſcientific perſons, and from the knowledge of the ſubject of elaſtic fluids, which has, of late years, been wonderfully promoted; the nature of thoſe damps is at preſent pretty well aſcertained, and their effects may be ſufficiently accounted for; excepting, indeed, two or three ſtrange ſtories, which are in need either of hiſtorical confirmation, or of a much deeper philoſophical inveſtigation.

The general effect of the damps is a contamination of the common, or reſpirable, atmoſpherical air; by the admixture, not indeed of moiſture, as one might be led to underſtand by the name of damps, but of other elaſtic fluids, which are abſolutely unfit for animal reſpiration. *Carbonic acid gas*, (formerly called *fixed air*,) *azotic gas*, (formerly called *phlogiſticated air*,) and *hydrogen gas*, or *inflammable air*, are the three elaſtic fluids which generally, if not always, produce the damps: we ſhall, therefore, briefly premiſe the principal properties of theſe gaſes; in order that the nature of the damps may be underſtood without much circumlocution.

Carbonic acid gas is abſolutely unfit for reſpiration or for combuſtion; inſomuch, that an animal confined in it, will be deprived of life rather ſooner than if he were confined under water. A lighted candle or torch brought within a quantity of this gas, is extinguiſhed as readily as if it were dipped in water. This gas is heavier than common air, in the proportion of three to two; hence, when it iſſues out of the earth in hollow or ſheltered places, it remains for a conſiderable time in a ſtratum cloſe to the bottom of the place. Carbonic acid gas conſiſts of 72 parts of oxygen, and 28 parts of charcoal.

Azotic gas is likewiſe unfit for reſpiration and for combuſtion. Its ſpecific gravity is very little below that of common air. It is that gas which forms about three-fourths of the atmoſpherical fluid, the other quarter conſiſting principally of oxygen air. It is produced, or rather left by itſelf, whenever the oxygen of the atmoſpherical air is abſorbed, as is the caſe in combuſtion, reſpiration, and various other proceſſes.

Hydrogen gas is, by itſelf, utterly unfit for animal reſpiration; but when mixed with common air, it may be breathed with impunity. In its pureſt ſtate, hydrogen gas weighs rather leſs than the twelfth part of an equal bulk of common air; but as it is capable of holding in ſolution water, ſulphur, phoſphorus, carbon, &c. ſo its ſpecific gravity generally exceeds that which has been juſt ſtated; it is always, however, much lighter than common air; hence, when it occurs in mines, it is either actually iſſuing out of crevices, or it is lodged under the roofs of thoſe excavations. This gas is highly inflammable, ſo that it may be fired by the flame of a candle, or a very ſmall electric ſpark, or even by a red-hot iron; but, like other combuſtibles, it will burn only in contact with common, or oxygen, air; hence, if a lighted candle be preſented to a certain quantity of hydrogen gas, this will burn either ſilently and progreſſively, or ſuddenly, and with an exploſion, according as the common air is contiguous to one ſide of it, or is more or leſs intimately mixed with it. The greateſt exploſion takes place, when four parts of hydrogen gas are mixed with ſix of common air; the tint of the flame varies according to the ſubſtance diſſolved in the gas. This gas is produced principally in the decompoſition of water; for water conſiſts of oxygen and hydrogen gas; from which circumſtance this gas has obtained its name. After the above compendious ſtatement of the nature and properties of the gaſes which produce the damps, we may proceed to deſcribe the phenomena.

Two ſorts of damps have been principally deſcribed: one has been called the *choke-damp*, from its ſuffocating quality; the other has been called the *fire-damp*, from its diſpoſition to take fire, and to burn either gently, or with an exploſion.

The choke-damps generally occur in old mines, called *waſtes* by the miners; being ſuch as formerly had been worked, but afterwards remained neglected. Theſe damps are likewiſe frequently met with in old wells, deep cellars, and other ſubterranean places wherein the air has long remained undiſturbed. They are formed by an accumulation of carbonic acid gas, which iſſues from the ground, and being much heavier than common air, remains next to the bottom, or ground, in a ſtratum of various depth, and more or leſs mixed with common air, or with azotic gas. The effects which have been produced by this ſort of damp are more than ſufficient to manifeſt the nature of the gas to which it is owing.

The perſons who happen to deſcend within this damp, inſtantly loſe their reſpiration, and fall down ſenſeleſs; nor can their death be prevented, unleſs they are quickly removed into the open atmoſpherical air; but even this method frequently proves ineffectual. Several caſes are recorded, where one perſon having been ſuffocated, a ſecond went down with a view to ſave him; but he alſo fell, and ſometimes even a third perſon met with the ſame fate. Perſons that have thus loſt their lives, on examination, have been found to exhibit all the marks of animals that have been ſuffocated in carbonic acid gas. One of the ſureſt methods of aſcertaining the preſence of this kind of damp in a well, mine, &c. is to ſend down a lighted candle; for if the candle continues to burn, you may conclude that a human being is perfectly ſafe in it; but if the candle goes out, then the

the preſence of the damp may be conſidered as certain; yet the human being may breathe, though not with perfect freedom, in air ſo far vitiated as not to be capable of ſupporting combuſtion. The miners diſtinguiſh this laſt ſtate of the air from that which is completely noxious, by the appearance of the candle; *viz.* if the flame and the redneſs or coaly part of the wick vaniſh at the ſame time, they conclude that the air is utterly unfit for reſpiration; but if the redneſs of the wick continues ſometime longer after the extinction of the flame, then they think it not very dangerous to deſcend into the place.

On account of the ſuperior gravity of the carbonic acid gas, and of its affinity to water, a greater quantity of vapour frequently remains ſuſpended in the choke-damp, than in common air; hence this damp is ſometimes viſible like a fog or miſt, and this is particularly the caſe in a cavern near Pyrmont.

It frequently happens that the ſtratum of carbonic acid gas is not higher than two or three feet; ſo that a man will be perfectly ſafe in it as long as he remains in a ſtanding poſition; but ſhould he attempt to lie down or to ſit, he would run the riſk of being ſuffocated.

The ſudden iſſue of this damp out of the earth, eſpecially when any digging has been performed, has ſometimes inſtantly killed the workmen.

In all ſuch caſes, ventilation (in whatever manner it may be practiſed) is the beſt method of diſſipating the damp. But ſhould a man be obliged to go down into a place thus infected, either for the purpoſe of ſaving another man, or for ſome other particular purpoſe, he would do well to fill a bladder with common air, and by means of a ſhort tube faſtened to the neck of the bladder, and held in his mouth, to breath that air; for a bladder thus filled will laſt him ſome minutes, during which time a great deal might be done. He might alſo take with him two or more bladders filled with common air, and furniſhed with ſtop-cocks, or merely with tubes ſtopped with corks.

Cautious miners ought always to have ſuch bladders, or ſuch like bags, filled with common air, by them; for they coſt little or nothing, and will effectually ſave their lives occaſionally.

When digging is to be performed in any place where the leaſt ſuſpicion of a ſudden iſſue of the choke-damp is entertained, it will be proper to keep a candle or lamp burning cloſe to the ground; for if any noxious gas happens to come forth, the going out of the flame will afford ſufficient warning to the workmen.

The ſudden iſſue of the choke-damp from the earth frequently occurs in the neigbourhood of volcanoes, upon old lavas, and old accumulation of aſhes or other volcanic productions. Numerous caſes of this ſort take place in the vicinity of mount Veſuvius, in Naples, where the noxious vapours, (called *mofete* by the inhabitants,) ſuddenly enter houſes, cellars, &c. to the great annoyance of the inhabitants, who, as well as other animals, are ſometimes killed by them. See ſir William Hamilton's various accounts of the mount Veſuvius and its eruptions, in the Philoſophical Tranſactions, for 30 or 40 years paſt. Some of the ſcientific perſons of the above-mentioned country have occaſionally endeavoured to aſcertain the nature of the gas which produces thoſe mofete; and from their experiments it appears, that the greateſt part of the gas is carbonic acid, but more or leſs mixed with azotic gas, and frequently accompanied with ſulphureous and arſenical vapours. A remarkable inſtance of a continual ſtream of carbonic acid gas iſſuing from the earth, occurs near the city of Naples. At about five or ſix miles from that city, near the foot of a hill, there is a famous cave called *grotta del cane* in the Italian language. This grotto is about fourteen feet long, and nearly ſeven feet high at the entrance. On the bottom of it, which is nearly on the ſame level with the adjacent external ground, there is at all times a ſtratum of carbonic acid gas or choke-damp, which is continually coming out of the earth, through the fiſſures which are pretty apparent on the ground; and where the production of ſuch gas has been remarked from time immemorial. Animals of different ſpecies, as well as human beings who ſheltered themſelves in this grotto, were at times found dead in it, in conſequence of which a door was placed to the aperture of it, which is now only opened occaſionally. The experiments uſually ſhewn to the curious who viſit this grotto, are, that of bringing a lighted torch or lighted piece of paper near the bottom or floor; the flame of which is extinguiſhed as ſoon as it comes within about 14 inches of the ground; and ſecondly that of confining a dog with its head cloſe to the ground for about a minute. The reſpiration of the animal is inſtantly affected, and its ſtrength fails, ſo as to remain apparently dead; but on being expoſed to the ambient air out of the grotto, if it be not too far gone, the poor animal will gradually recover its reſpiration and its ſtrength. It is from this uſual experiment that this grotto has obtained its name: *cane* being the Italian for a dog.

Joannes Caramuelis, in his Mathefis Nova, printed in the year 1670, relates ſome experiments made by himſelf and others upon the noxious elaſtic fluid of this grotto, which are very remarkable, conſidering the time in which they were made. He obſerves, that the ſmoke of a candle, extinguiſhed near the bottom of this grotto, is entirely retained within the ſtratum of gas; and that if part of that ſmoke happened to be driven out of the grotto, it deſcended like water falling from the edge of a tub. Had he been acquainted with the nature of carbonic acid gas, he would have eaſily underſtood that the ſmoke was retained on account of the great attraction between that gas and the aqueous particles; and that it deſcended, when driven out of the grotto, on account of the great ſpecific gravity of the carbonic acid gas with which it was combined. The ſame ingenious perſon relates another experiment, which tends to prove the acid quality of the gas concerned, which quality has long after been fully aſcertained. He and his companions placed the head of an alembic on the bottom of the grotto; and as this inſtrument was colder than the air of the grotto, which generally is pretty warm, it collected a few drops of a watery fluid, which, to the taſte of his companions, ſeemed to be acidulous. In the preſent ſtate of knowledge this experiment is eaſily explained; it being evident that the head of the alembic condenſed the watery particles from the air of the grotto, and theſe became acidulous in conſequence of their becoming impregnated with the carbonic acid gas. The ground in the neighbourhood of grotto del cane ſhews manifeſt ſigns of ſubterranean fires or fermentation, as it abounds with ſulphur, hot ſprings, emanations of ſmoke, &c.

Fire-damp, though conſiderably heavier than pure hydrogen gas, is yet much lighter than atmoſpheric air. Hence where a tolerable ventilation is kept up, it ſeldom accumulates to a dangerous amount in the ſhafts, or vertical pits, that are open to the air; but in the horizontal galleries, where it occupies the upper part, forming a ſtratum, lying immediately in contact with the roof. It generally makes its firſt appearance in the cracks and crevices of the coal,

particularly where it is moiſt and abounding in pyrites. While it is thus oozing out, it often burns with a quiet light blue lambent flame, which, on the contact of a candle, explodes with a hiſſing noiſe, and, for a time, is extinguiſhed or forced into an adjacent crevice. In proportion as the water is drained off, the production of this gas diminiſhes, ſo that the dryeſt mines are the leaſt infeſted with it. Heat contributes much to its generation; hence it is generally more abundant during the ſummer than the winter months. If it is not cleared out of the mine, in proportion as it is produced, it ſoon begins to accumulate in the upper part of the galleries, on which account it is a caution well worth remembering, by thoſe who viſit a coal-pit, to hold their candles as low down as poſſible. The gas thus continues to increaſe without producing any material inconvenience to the miners, till, at length, it comes in contact with ſome lighted candle: the flame is immediately increaſed to five or ſix times its uſual ſize, and in a ſecond or two afterwards, the whole body of gas takes fire: a volume of flame and black ſmoke darts from the gallery into the vertical ſhafts, whence it riſes into the air with a loud ſtunning exploſion, throwing up, to a conſiderable height, men, large beams of timber, and every thing elſe that happens to be in its way. As ſoon as the exploſion has taken place, the external air ruſhes violently into the mine to fill up the vacuum, and the reſidual inflammable gas again takes fire, and burns quietly for a few minutes, till it is extinguiſhed.

When an accident of this kind happens, there are three diſtinct dangers to which the miners within its influence are expoſed. In the firſt place, thoſe who are in the gallery where the inflammation commences are ſcorched by the fire, and are alſo liable to ſuffer ſeverely from the ruſhing in of the air to ſupply the vacuum cauſed by the exploſion. Secondly, thoſe who happen to be in the ſhaft, or near the mouth of the gallery, are either blown up out of the pit, or are killed by being violently forced againſt its ſides. In the latter of theſe ſituations there is no poſſibility of eſcape; but thoſe who are not exploded, often ſave their lives by throwing themſelves on their faces on the ground, and covering themſelves, as well as they can, with ſmall coal, &c. till the danger is paſt. No particular odour is perceivable before the inflammation, but afterwards a ſtrong and ſuffocating ſmell of burning ſulphur becomes very obvious.

We ſhall now give a ſummary of the facts that were collected from the miners by Mr. Jeſſop, as given in the Philoſophical Tranſactions, N° 119.

1. "Thoſe who are in the place where the vapour is fired, ſuddenly find themſelves ſurrounded with flames, but hear little or no noiſe; though thoſe who are in places adjacent, or above ground, hear a very great one. 2. Thoſe who are ſurrounded by the inflamed vapour feel themſelves ſcorched or burnt, but are not moved out of their places; though ſuch as unhappily ſtand in the way of it, are commonly killed by the violence of the ſhock, and are often thrown with great force out of the mouth of the pit; nor are the heavieſt machines found able to reſiſt the impetuoſity of the blaſt. 3. No ſmell is perceived before the fire, but a very ſtrong one of brimſtone is afterwards felt. 4. The vapour lies towards the roof, and is not perceived if the candles are held low; but when theſe are held higher, the damp deſcends like a black miſt, and catches hold of the flame, lengthening it to two or three hands full; and this appearance ceaſes when the candles are held nearer the ground. 5. The flame continues in the vault for ſeveral minutes after the crack. 6. Its colour is blue, ſomething inclining to green, and very bright. 7. On the exploſion of the vapour, a dark ſmoke, like that produced from firing gun-powder, is perceived. 8. Damps are generally obſerved to come about the latter end of May, and to continue during the heat of ſummer. They return ſeveral times during the ſummer ſeaſon, but obſerve no certain rule."

The fire-damps generally occur in coal-mines; and in the Philoſophical Tranſactions, N° 136, we find ſeveral accounts and obſervations made in digging ſuch mines; and from theſe we ſhall compendiouſly extract the moſt uſeful particulars.

"After they had gone, the account ſays, a conſiderable way under ground, and were ſcanted of wind, the fire-damps did begin by little and little to breed, and to appear in crevices and ſlits of the coal where water had been before the opening of the coal, with a ſmall blueiſh flame, working and moving continually; but not out of its firſt ſeat, unleſs the workmen held their candles to it; and then being weak, the blaze of the candle would drive it with a ſudden fiz away to another crevice, where it would ſoon after appear blazing and moving as formerly.

"This mine was neglected for a certain time; and upon a morning, the firſt collier that went down with his candle in his hand, the damp preſently darted out ſo violently at his candle, that it ſtruck the man quite down, ſinged his hair and clothes, and diſabled him for a while. After the ceſſation of work for ſome days, in going down the firſt time, the fire-damps have often exploded with terrible effects."

The bad effects of the fire-damps may, in a great meaſure, if not entirely, be prevented by vigilance, and by a proper conformation of the excavations. In digging a mine, due attention ought to be paid to the roof of it, which ought to be ſhaped ſo as in ſome meaſure to reſemble an inverted funnel, *viz.* having the higheſt part of it near to the ſhaft or ſhank; for, by this means, the hydrogen gas, or fire-damp, would aſcend into the atmoſphere as ſoon as it is generated; nor could it be lodged any where in ſo great a quantity as to produce any dangerous effects. In mines already formed, and eſpecially when they have not been worked for a certain time, it is always proper to let down two or three lighted candles by means of a rope; and if theſe produce no inflammation, then a man with a candle ought to be ſent down, who, after advancing a few ſteps into the mine, ought to lay himſelf down, and ought to lift up a lighted candle on the top of a pole as high as he can; for the inflammable gas which always occupies the upper part of the mine, may, in that caſe, be exploded with hardly any danger to the man.

When miners are actually working in a mine, the accumulation of the inflammable gas may be eaſily prevented, *viz.* by firing it off immediately as it iſſues out of the various crevices.

Ventilation is the beſt method of removing damps out of mines, and at the ſame time of giving wholeſome air to the labourers; but this is hardly practicable in ſuch mines as are furniſhed with one ſhaft or aperture. It is, therefore, always to be wiſhed that mines of any extent ſhould be furniſhed with two or more ſhafts in proportion to their extent. The ventilation then may be promoted by lighting a fire under one of thoſe ſhafts; for by this means the air of that ſhaft being rarefied, will be forced to aſcend, and of conſequence an influx of pure atmoſpherical air will enter the mine through the other ſhaft or ſhafts. Several mechanical methods have alſo been uſed for the ventilation of mines. The nature of the gas which produces the fire-damp, as well as that which produces the choke-damp, has been frequently

quently ſubjected to philoſophical experiments, with a view to aſcertain both its origin and its qualities. Sir James Lowther collected the gas of the fire-damps in bladders, and thus brought it up to London, where, upon trial, he found, that on being let out of the bladders, it would take fire at the flame of a candle. But ſome recent experiments of Dr. William Henry, on a ſimilar ſort of gas, were performed with greater care; and their reſults, which we ſhall ſubjoin, are much more ſatisfactory.

"About the cloſe, Dr. Henry ſays, of 1806, I received from the Rev. W. Turner of Newcaſtle-on-Tyne, two bladders filled with the fire-damp, which had been procured from a coal-mine in the neighbourhood of that town. It was caught by luting a common funnel over the mouth of a *blower* (*viz.* one of thoſe holes or crevices in the coal, from which the fire-damp iſſues, ſometimes with conſiderable force,) and tying a compreſſed bladder on the pipe of the funnel, after the gas had iſſued from it for ſome time. My experiments were made on the gas, about ſeven days after its being firſt collected. At that time the bladders were perfectly dry, and ſhewed no ſigns of putrefaction."

The general reſults of theſe experiments, (as ſtated in a memoir which was read in January 1807, before the Medical Society of Edinburgh,) are the following. The gas was found, by the teſt of nitric oxyd, uſed in Mr. Dalton's method, to contain about $\frac{2}{3}$ its bulk of common air. It had a diſagreeable ſmell. When ſet on fire, as it iſſued from the orifice of a ſmall pipe, it burned with a dark blue flame; and a long conical glaſs veſſel, held over the flame, was ſoon bedewed with moiſture. Mixed with common air, it did not detonate on the approach of a lighted taper, at leaſt in any proportion that was tried. The utmoſt effect was a deep blue flame, which ſpread quickly through the veſſel, but was not accompanied with any noiſe. With oxygen gas, however, it exploded, and gave a loud report. On agitation with lime water, it loſt about $\frac{1}{60}$th of its bulk. The niceſt teſts did not diſcover any admixture of ſulphurated hydrogen. One hundred parts by meaſure appeared, therefore, to conſiſt of

63.34 atmoſpherical air
1.66 carbonic acid
35.00 inflammable gas

100.00

"The nature of the inflammable gas was next aſcertained by detonation with oxygen gas. Reducing the reſults to a general average, and excluding the common air, the really inflammable part of the gas required for combuſtion about twice its bulk of oxygen; and gave its own volume of carbonic acid. Hence the inflammable portion of the gas was *carburetted hydrogen*. From the experiments of Mr. Dalton on the gas from ſtagnant water, and my own obtained by diſtilling pit-coal, the fire-damp appears to differ very little from both theſe gaſſes.

"It was deſirable, however, to repeat the analyſis of fire-damp, leſs adulterated with common air; and for this purpoſe a quantity was collected (as it iſſued through water on the floor of a mine) in an inverted bottle, which was well corked, and tied over with a bladder. Happening to paſs through Newcaſtle laſt ſpring, I carried this gas with me to Edinburgh; and, having no opportunity of making experiments upon it there, my friend Dr. Thomſon was ſo good as to undertake its analyſis, and to furniſh me with the following reſults.

"From the action of nitrous gas and lime-water, the gas appeared by Dr. Thomſon's experiments, to contain in 100 meaſures,

63.0 inflammable gas
6.5 oxygen
25.5 azote
5.0 carbonic acid

100.0."

Notwithſtanding all the above-mentioned facts, experiments, and obſervations, the real origin of the gaſſes which produce the damps is by no means thoroughly underſtood. Indeed the origin of the carbonic acid which produces the choke-damp may pretty well be accounted for, conſidering the immenſe quantity of that gas which is combined with calcareous ſtones and other minerals; alſo that the action of heat eaſily extricates that gas from the above-mentioned minerals; ſo that whenever any fermentation, or any heat ariſing from various cauſes, happens to act upon ſuch minerals, the extrication of carbonic acid is a natural conſequence. But the origin of the hydrogen gas is not equally clear. It was formerly a prevailing opinion, that the inflammable gas was furniſhed by the decompoſition of water on ſtrata of pyrites, eſpecially thoſe of a martial nature; conſidering that the ſolution of iron, and of pyrites itſelf, in various menſtrua, produces abundance of that gas. But if the hydrogen were produced by the action of pyrites upon water, a quantity of ſulphur would be naturally contained in the gas, which does not appear to be the caſe from the above-mentioned experiments of Drs. Henry and Thomſon, who expreſsly mention their not having found any ſulphuretted hydrogen in the fire-damp which they examined.

If we conſider the various ſucceſſive ſtrata of different materials which almoſt every excavation, and eſpecially coal and metallic mines, exhibit to our view, a much more rational mode of accounting for the production of the inflammable gas perhaps would be, by attributing the decompoſition of water, and the conſequent extrication of the gas, to the agency of electricity, agreeably to the phenomena of that branch of it which is at preſent moſt advantageouſly cultivated under the name of *Galvanic* ELECTRICITY; which ſee.

Having thus ſtated every thing which ſeemed to be of importance with reſpect to the damps, which have infeſted from time immemorial, and do actually continue to infeſt mines of almoſt every kind; we ſhall cloſe this article with a ſhort account of two other, much leſs authentic, or much leſs known, kinds of damp. The account (which is contained in the Philoſophical Tranſactions, as given by the ſame Mr. Jeſſop, whom we mentioned above) is as follows:

"They call the third ſort the *peaſe-bloom damp*, becauſe, as they ſay, it ſmells like peaſe-bloom. They tell me it always comes in the ſummer-time; and thoſe grooves are not free which are never troubled with any other ſort of damps. I never heard that it was mortal; the ſcent, perhaps, freeing them from the danger of a ſurpriſe; but by reaſon of it many good grooves lie idle at the beſt and moſt profitable time of the year, when the ſubterraneous waters are the loweſt. They fancy it proceeds from the multitude of red-trefoil flowers, by them called *honey-ſuckles*, with which the lime-ſtone meadows in the Peak do much abound. The fourth damp is the ſtrangeſt and moſt peſtilential of any, if all be true which is ſaid concerning it. Thoſe who pretend to have ſeen it (for it is viſible) deſcribe it thus. In the higheſt part of the roof of thoſe paſſages which branch

out

out from the main groove, they often ſee a round thing hanging, about the bigneſs of a foot-ball, covered with a ſkin of the thickneſs and colour of a cob-web. This, they ſay, if it is broke by any accident, as the ſplinter of a ſtone, or the like, diſperſeth itſelf immediately, and ſuffocates all the company. Therefore, to prevent caſualties, as ſoon as they have eſpied it, they have a way, by the help of a ſtick and long rope, of breaking it at a diſtance; which done, they purify the place well with fire, before they dare enter it again. I dare not avouch the truth of this ſtory in all its circumſtances, becauſe the proof of it is impoſſible, ſince they ſay it kills all that are likely to bear witneſs to the particulars; neither do I deny but ſuch a thing may have been ſeen hanging on the roof, ſince I have heard many affirm it."

DAMPIER, WILLIAM, in *Biography*, an eminent navigator, was deſcended from a reſpectable family in Somerſetſhire. He was born in the year 1652. Having the misfortune to loſe his parents early, he was bound apprentice to the captain of a Newfoundland trader, at the age of 17. His firſt voyage was to France; and in the following year he went to Newfoundland. The ſeverity of the climate, and the attendant hardſhips of the voyage, made him almoſt reſolve that he would abandon for ever the difficulties of a maritime life. An opportunity, however, ſoon offering itſelf, he went out as common ſailor to the Eaſt Indies. In this ſituation he made a voyage to Bantam, and was fully ſatisfied with the experience which he obtained by the event. In 1673 he ſerved in the Dutch war, under ſir Edward Sprague, and was in two engagements. Sickneſs obliged him to land, and he ſpent ſome months with his brother; after which he went to Jamaica, as under manager in a plantation. From the Weſt Indies he went to Campeachy, and engaged with the logwood-cutters as a common workman. When he was tired of this buſineſs he returned to Jamaica, and thence to England. In 1679 he ſailed again for the Weſt Indies, meaning alſo to reviſit Campeachy; but he was perſuaded to join ſome pirates of different nations, who plundered any people over whom they could take advantage. With theſe Dampier croſſed the iſthmus of Darien in 1680, and ſpent that year in roving about the Peruvian coaſt, making attempts upon the ſeveral towns, ſome of which proved ſucceſsful, and in others they were repulſed with conſiderable loſs. In 1681 he recroſſed the iſthmus, and joined another fleet of theſe pirates which was cruiſing on the Spaniſh main: theſe purſued the ſame buſineſs, being prepared for any mode of acquiring gain that might offer. In one inſtance they took three veſſels with 1000 negroes on board; theſe Dampier would have taken and employed in the gold-mines, but his fellow-adventurers overruled the project. His next attempt was to capture the rich plate fleet which was conveying the treaſure of Peru to Panama; but in this they were diſappointed. In this predatory courſe Dampier continued till 1688, when he perſuaded his captain to leave him at Nicobar, where he thought, by conforming to the manners of the natives, and learning their language, he might be able to carry on an advantageous trade in ambergris. With him ſeven others were ſet on ſhore. They attempted to navigate a ſmall boat to Achin in Sumatra. At firſt every thing ſeemed favourable to the project. On the fourth day, when they had made but ſmall progreſs in their voyage, the wind roſe, the heavens lowered, and every appearance ſeemed to threaten them with an inextricable and overwhelming danger. They agreed to furl their ſails, and give themſelves to the fury of the element, which they had no means to avoid, nor power to contend with. Preparations being made, they waited the impending ſtorm with anxious and gloomy apprehenſions. The event was more tremendous than they had even anticipated. The ſea ran mountains high, and breaking over their canoe, every moment threatened to overwhelm her in the deep. Dreadful as the ſituation was by day, it ſeemed ſtill more terrible as the darkneſs approached. All the dangers to which Dampier had been expoſed, were not to be compared to this: "The ſky," ſays he, "looked very black, being wrapped in ſable clouds; the wind blew hard, and the ſea was laſhed into foam around us. A dark night was coming on, and no land to ſhelter us, and our little bark in danger of being ſwallowed up by every wave. What gave a deeper tinge to our diſtreſs, was the reflection, that none of us were prepared to enter on another ſtate of exiſtence with the confidence of hope. I had encountered many imminent dangers before this; but compared with the preſent, the worſt of them was only a play-game. I muſt confeſs that I was in great perturbation of mind: other diſtreſſes came out upon me with ſuch dreadful ſolemnity. A ſudden ſkirmiſh or engagement was nothing, when the blood was warm, and invigorated the heart by the glow of expectation; but here I had a lingering view of impending fate, with little or no hopes of avoiding it. My courage, which had hitherto kept me up, now failed me; and I made very ſad reflections on my former life, and looked back with horror and deteſtation on actions which before I could not reliſh, but at the remembrance of which I now trembled. I had long repented of my roving life; but never with ſuch ſincere contrition before." The whole of their ſufferings is deſcribed by Dampier with admirable force; nevertheleſs, they ſurmounted them all, and landed ſafely at Sumatra. Long continued ſickneſs was, however, the conſequence of their want of reſt, and of neceſſary food, from the effects of which ſome of the party never recovered. Dampier himſelf was not free from the attendant complaints for a twelvemonth and more. After this he made ſeveral voyages to Tonquin, Malacca, and other parts of the Eaſt Indies. In 1691 he returned home, having completed the circumnavigation of the globe. As his property, he brought home a native of one of the ſpice iſlands, who was the ſon of an Indian chief, and was called here the Painted Prince, on account of his being ſo curiouſly tattowed. This youth was purchaſed in the way of trade, was ſhewn in England as a ſtrange ſight, and at length died of the ſmall-pox at Oxford. We know nothing of the manner in which Dampier ſpent his time during the next ſeven or eight years; but in 1699 he was appointed to the command of the Roebuck, a ſloop of twelve guns, with fifty men. He ſailed firſt for the Brazils, and thence he made to the weſtern coaſt of New Holland, where he arrived on the firſt of Auguſt. He next ſailed to Timor, and thence to the coaſt of New Guinea. This he found terminated by an iſland, which he ſailed round, and named New Britain. He returned to Timor in May, and proceeding by the Cape of Good Hope, arrived off the iſle of Aſcenſion, in February 1701. Here his veſſel became leaky, and foundered; but he and his crew reached the iſland, where they remained till they were brought away by an Eaſt India ſhip. He afterwards accompanied captain Woodes Rogers in a voyage round the world. The time of Dampier's death is not known. The account of his voyages has been very frequently reprinted; and the ſubſtance of them has been incorporated in a hundred different compilations. His own volumes contain many curious, valuable, and important obſervations, in a plain but manly ſtyle, and bearing all the marks of fidelity. His remarks diſplay much nautical, and ſome philoſophical knowledge.

A portrait

A portrait of Dampier is preſerved in the Trinity Houſe.
Dampier's Voyages.

DAMPIER'S *Straits*, in *Geography*, lie between the N.E. point of New Guinea, and the S.W. point of New Britain; S. lat. 6° 15′. E. long. from Paris 146°.

DAMPIERRE, a ſmall town of France, in the department of the Upper Saône, chief place of a canton, in the diſtrict of Gray. It has 1344 and the canton 12,123 inhabitants, diſperſed in 33 communes upon a territorial extent of 255 kiliometres.—Alſo, a ſmall town of France, in the department of the Jura, diſtrict of Dôle, with a population of 465 individuals, and chief place of a canton which, in 15 communes and upon 127½ kiliometres, contains 5905 inhabitants.—Alſo, a ſmall town of France, in the department of the Lower Charente, 9 miles N. of Saint Jean d'Angely.—Alſo, a ſmall town of France, in the department of the Côte d'or, 18 miles N.E. of Dijon.—Alſo, a ſmall town of France, with a fine caſtle, in the department of Seine and Oiſe, 3 miles W. of Chevreuſe.

DAMRABAD, a town of Perſia, in the province of Segeſtan; 180 miles S.W. of Zareng.

DAMSEE, a lake of Germany, in the circle of Upper Saxony, and Ucker Mark of Brandenburg; 9 miles N.W. of Prenzlow.

DAMSEL, DAMOISEL, or DAMOISEAU, an appellation anciently given to all young people of genteel or noble extraction of either ſex, *e. gr.* to the ſons and daughters of knights, barons, and even of kings.

Thus, in hiſtory, we read of the damſel Pepin, damſel Louis le Gros, damſel Richard, prince of Wales.

Paſquier will have the word a diminutive of dam, an ancient name for lord; as in ſome authors we read Dam Dieu for lord God; dam chevalier, &c. Though in its feminine ſenſe he takes it to come from dame.—Others derive the word from domicellus, or *domnicellus*, a diminutive of domnus, quaſi parvus dominus: accordingly, Du Cange obſerves, that it has been ſometimes written domenger.

They who hold the ſignory of Commercy, M. de la Roque tells us, anciently held it in the title of damoiſeau: and M. de Marca aſſures us, that the nobleſſe of Bern is ſtill divided into three bodies, or claſſes; the barons, the cavers, and the damſels, domicellos, called in that country domengers.

The kings of Denmark and Sweden have the ſame title, as appears from Pontanus's Hiſt. of Denmark, lib. vii. and viii. and Henry of Upſal's Hiſt. of Suec. lib. iii.

From the ſons of kings, the appellation paſſed to thoſe of great lords and barons; and, at length, to thoſe of gentlemen who were not yet knights.

DAMSEL, at preſent, is applied to all maids, or girls, not yet married; provided they be not of the loweſt claſs of people.

DAMSEL is ſometimes alſo applied to a kind of utenſil put in beds, to warm old men's feet.

It conſiſts of a hot iron incloſed in a hollow cylinder, which is wrapped round with linen cloth, and keeps its warmth a long time. Some call it a nun.

DAMSON TREE, in *Botany*. See CHRYSOPHYLLUM and PRUNUS.

DAMSONS. See PRUNES.

DAMSONG, in *Geography*, a town of Aſia, in the country of Bootan; 54 miles S.W. of Taffaſudon. N. lat. 27° 11′. E. long. 88° 24′.

DAMSTER, a river of Germany, which runs into the Ems at Delfzyl.

DAMVILLE, a ſmall town of France, in the department of the Eure, in the diſtrict of Evreux; 12 miles S. of Evreux, famous for its good cyder. It has 720 inhabitants, and is the chief place of a canton, which reckons a population of 7187 individuals, and 27 communes, upon a territorial extent of 190 kiliometres.

DAMVILLERS, or DAMVILLIERS, a ſmall town of France, in the department of the Meuſe, and chief place of a canton, in the diſtrict of Montmedy; 18 miles N.E. of Verdun, and 36 S.W. of Luxembourg. N. lat. 49° 22′. It has 809 inhabitants, and the canton contains a population of 9117 individuals, and 24 communes, upon a territorial extent of 240 kiliometres. Damvillers had been fortified by Charles V. in 1528; but having been ceded to France at the peace of the Pyrenées, Louis XIV. demoliſhed its fortifications in 1673.

DAN, *Tribe of*, in *Ancient Geography*, lay S.W. of the tribe of Judah, between it and the Mediterranean, contiguous to that of Simeon. It was bounded on the N. by Ephraim, on the W. by the Philiſtines and the Mediterranean, on the S. by Simeon, and on the E. by Judah and Benjamin. Its greateſt length, from north to ſouth, did not exceed 40 miles; on the north ſide it was very narrow, and not above 25 broad on the ſouth. Its ſoil was fertile, and its inhabitants induſtrious and brave; ſome of them, diſdaining confinement within their own limits, advanced, ſo far as the city of Laiſh, in the utmoſt verge north of Paleſtine, after new ſettlements. The country abounded with corn, wine, oil, fruits, and all other neceſſaries. In this diſtrict was the valley called Nahal Eſcol, &c. of the grapes; whence, the ſpies ſent by Moſes brought excellent ſpecimens of its fertility to the camp of the Iſraelites. Dan had within its ſmall extent ſeveral cities of note; the chief of which were Joppa, Jamnia, Caſphin, Thimnah, Beth-Shemeſh, Ajalon, Lachiſh, Modin, Elteke, Laki, Gibbethen, and Zora or Sora.

DAN, a city in the northern part of Paleſtine, in the tribe of Naphtali, which had formerly been called Laiſh or Laſhem; but being taken by a colony of Danites, they gave it the name of their own tribe. This city became infamous for the calf ſet up by Jeroboam, which was reſorted to by all the revolted tribes on this ſide; and as it ſtood on the utmoſt verge of Judæa, as Beer-ſheba did on the oppoſite; this circumſtance gave riſe to the common proverb, "from Dan to Beer-ſheba." When the Romans took it, they gave it the name of Paneas, and beſtowed it on Philip, the ſon of Herod, who called it Cæſarea Philippi. But ſome writers place Dan at the foot of mount Libanus, on the banks of the Jordan, at the diſtance of 4 miles from Paneas, on the ſide of Tyre.

DAN, *Camp of*, lay in Paleſtine, between Saraa and Eſtahol, in the tribe of Dan. In this camp Sampſon was interred.

DAN, in *Geography*, a conſiderable river of America, in North Carolina, which unites with the Staunton, and forms the Roanoke. The famous Burſted hill is ſituated on the bank of the Dan in Virginia, near the borders of N. Carolina. This hill appears to have been an ancient volcano, as large rocks of lava, of great weight, lie on its ſummit, and the crater is partly filled and covered with large trees. N. lat. 36° 34′. W. long. 78° 50′.

DANA, a new town of America, in the ſtate of Maſſachuſetts, and county of Worceſter, formed from the corners of Greenwich, in the county of Hampſhire, and Hardwick and Peterſham, in Worceſter county.

DANA, or *Dagana*, in *Ancient Geography*, a maritime town of Aſia, in the iſland of Taprobana, according to Ptolemy; who adds, that it was dedicated to the moon.—Alſo, a large,

rich, and populous town of Cappadocia, where Cyrus ſojourned three days.

DANABA, a town of Aſia, in Syria, placed by Ptolemy in the Palmyrene territory, S.W. of Palmyra.

DANÆ, or DANATI, a town of Aſia, in the Pontus Polemoniacus, ſituated near the ſprings of the river Iris, in the 41ſt degree of latitude, according to Ptolemy.

DANAE, or *Danace*, Δανακη, or Δανακκη, in *Antiquity*, a coin current among the barbarians, being ſomewhat more than the obolus. This they put into the mouths of dead people, to pay for their paſſage over the river Acheron.

DANAE, in *Fabulous Hiſtory*, the only daughter of Acriſius, who, having learnt from the oracle, that his grandſon would bereave him of his crown and life, ſhut her up in a brazen tower, and would give ear to no propoſal of marriage for her. In the mean time, Prætus, his brother, being deſperately in love with his niece, corrupted the fidelity of her keepers by means of money, and having obtained acceſs to her, ſhe became the mother of Perſeus. This fable is comprehended by Ovid in a ſingle line (Met. l. vi.); "Perſea quam pluvio Danaé conceperat auro." Horace has given it a moral application, in order to demonſtrate the power of gold over mankind:

> "Aurum per medios ire ſatellites
> Novit, &c."

In order to palliate the diſgrace of this intrigue, it was given out, that Jupiter, enamoured of Danae, had transformed himſelf into a ſhower of gold; but it was more probable, that Prætus, if we may believe Voſſius, (De Orig. et Progr. Idol. l. i.) took upon him the ſurname of Jupiter. Pauſanias (in Corinth.) mentions the tower, or rather apartment of braſs, in which Danae had been ſhut up, and aſſures us, that it ſubſiſted till the time of Perilaus, the tyrant of Argos, who demoliſhed it; adding, that even in his time, ſome remains of the ſubterraneous palace, containing Danae's chamber, were to be ſeen. Danae, being delivered of Perſeus, was expoſed, by Acriſius, with her ſon, to the dangers of the ſea, but, at length, hoſpitably received by the king of Seriphus, one of the Cyclades iſlands, who educated young Perſeus. After ſeveral adventures, Perſeus went with his mother into Greece, diſpoſſeſſed Prætus of his territories, and re-eſtabliſhed his grandfather, Acriſius, who had been dethroned, in his dominions; but as he was endeavouring to ſhew his dexterity in playing at quoits, he flung his quoit by accident at Acriſius and ſlew him. Pauſan. in Corinth.

DANÆA, in *Botany*, a moſt curious genus of dorſiferous ferns, was firſt ſeparated by Dr. Smith from the *Aſplenium* of Linnæus, to which it has as little affinity as any two plants of the ſame natural order can have to each other, and was named by him in honour of his friend profeſſor Dana of Turin, the pupil and ſucceſſor of the celebrated Allioni, who had already dedicated a plant to Mr. Dana, which proves to be no other than *Liguſticum cornubienſe*. Sm. in Mem. de l'Acad. de Turin, v. 5. 420, t. 9. f. 11. Tracts, 260, t. 1. f. 11. Swartz, Filic. 167. Claſs and order, *cryptogamia filices*; ſect. *Exannulatæ*. Nat. Ord. *Filices dorſiferæ*

Eſſ. Ch. *Capſules* of one cell, burſting by a pore at the ſummit, accumulated together in two parallel rows.

A double row of crowded capſules is arranged along each vein of the fructifying leaflets, forming all together an oblong, turgid, ſomewhat cylindrical body, perforated with two rows of pores along its upper ſurface, which are the orifices of the capſules. Theſe are not, as Dr. Swartz ſuppoſed, always open, but continue cloſed till the ſeeds are ripe, which are extremely minute and abundant, reſembling the fineſt duſt. The ſame great cryptogamiſt errs, as we preſume to think, in conſidering theſe rows or congeries of capſules as ſingle capſules of many cells. That the idea we have given of them above, not without much conſideration, is moſt correct, appears from their perfectly indeterminate number of theſe little capſules, which is limited chiefly by the ſhape or dimenſions of the leaf, and the rows being ſometimes, though rarely, from accidental circumſtances, interrupted.

Sp. 1. D. *nodoſa*. Sm. Tracts, 260. Swartz Fil. 167. Cavan. Leccion. 281. (Aſplenium nodoſum; Linn. Sp. Pl. 1539. Lingua cervina nodoſa major. Plum. Fil. 90. t. 108.) Stalk ſcarcely winged; leaflets linear-oblong, ſeſſile, pointed, nearly entire, covered with capſules to the edge. Radical ſcales acute. A native of Martinico and Hiſpaniola, in damp ſhady woods near rivers, according to Plumier who firſt deſcribed it. It is a large and handſome fern. *Root* creeping, thick and knotty, producing two alternate rows of *fronds*, accompanied at their baſe with acute undivided ſcales. Each *frond* is about four feet high, ſimply pinnate. The *ſtalk* ſmoothiſh, juicy, knotty, cylindrical with a channel in front, ſcarcely if at all winged, even in the upper part. *Leaflets* oppoſite from each knot, ſeſſile, ſix or eight inches long, oblong, almoſt linear, entire, wavy, with a taper point, ſmooth on both ſides, with one rib, and innumerable, fine, ſtraight, tranſverſe, parallel veins, moſtly in pairs. *Capſules* cloſely covering the leaflets of ſome ſmaller fronds, from whoſe veins they originate, of a lightiſh brown when ripe, each row extending from the main rib very nearly to the margin, with rudiments of a membranous partition between the rows.

2. D. *elliptica*. (Filix major, in pinnas tantum diviſa, raras, latiores, oblongas, ſtriatas, ex adverſo ſitas, et non crenatas. Sloane Jamaic. v. 1. 85. t. 41. f. 1.) Stalk ſcarcely winged; leaflets elliptic-oblong, ſtalked, pointed, nearly entire, bare of fructification near the margin. Obſerved by Sloane in Jamaica, from whence the younger Linnæus obtained a ſpecimen. The *fronds* are but half as tall as in the former, and their leaflets half as long, though ſomewhat broader and elliptical. The latter, moreover, ſtand on ſhort partial footſtalks. The rows of *capſules* ſcarcely extend ſo near to the edge of the leaflet on which they grow, but are more remarkably ſeparated from each other, at leaſt in a half-ripe ſtate, by a double prominent undulated membrane. The frond in our ſpecimen is clothed with minute *jungermanniæ*, evincing its moiſt and ſhady place of growth.

3. D. *alata*. Sm. Tracts, 261. Sw. Fil. 167. (Lingua cervina nodoſa minor. Plum. Fil. 91. t. 109.) Stalk winged towards the top; leaflets ſerrated, bare of fructification near the margin. Radical ſcales obtuſe and jagged. A native of Martinico. *Fronds* about two or three feet high, ſcaly. *Leaflets* numerous, from one to two inches long, on ſhort ſtalks, oblong, criſped and ſerrated, ſcarcely pointed. Rows of *capſules* ſhorter and broader in proportion than in either of the former, with double, ſtraight, intervening membranes, and not extending to the margins of the leaflets, ſometimes by a conſiderable diſtance.

4. D. *ſimplicifolia*. Rudge Pl. Guian. 24. t. 36. Frond ſimple, elliptic-lanceolate, entire. Communicated by T. F. Forſter, Eſq. F.L.S., who received it from Guiana. This differs from all the reſt in its ſimple *fronds*, which are ſix or eight inches long, lanceolate, inclining to elliptic, acute, entire, ſmooth, ſomewhat oblique, each ſtanding on a reddiſh ſcaly *ſtalk*, above its own length. The fertile fronds are covered with crowded ſlender double lines of ſmall *capſules*,

ſules, ſcarcely extending to the margin, with double broadiſh intervening membranes.

Perhaps theſe membranes are a true cover or *involucrum* in this genus. They do not originate from any vein, for each double row of capſules is inſerted into that part.

We have a fern from the iſland of St. Kitt's, with a winged ſtalk, and alternate crenate leaflets, whoſe whole aſpect declares its cloſe affinity to theſe *Danææ*, but without fructification we dare not aſſociate it with them. S.

DANAIDES, in the *Ancient Mythology*, the daughters of Danais, or Danaus, eleventh king of Argos, and brother of Ægyptus.

They were fifty in number, and were eſpouſed to the fifty ſons of their uncle Ægyptus.

Danaus fearing the accompliſhment of an oracle, which had foretold that he ſhould be expelled his kingdom by a ſon-in-law, perſuaded his daughters to murder, each of them, her huſband, the firſt night; which they performed, all but Hypermneſtra, who ſpared her huſband Lynceus.

In vengeance for this crime of the forty-nine Danaides, the poets have condemned them to hell, to be continually employed in filling a caſk perforated at bottom. Euſebius and ſome others ſuggeſt, that what had given riſe to this fiction was, that they had laboured in digging wells in Argos, where ſome of them had been continually employed in drawing water by pumps, which is a painful exerciſe: whence thoſe who were condemned to this labour took occaſion to ſay, that the gods, to puniſh theſe princeſſes, had ſentenced them in hell to fill a veſſel full of holes. The learned Bryant, conceiving that the words νηυς and ναυς are derived from Nau and Noah, obſerves, that the name of Danaus relates not to a man, but is in reality "da Näus," and ſignifies literally "the ſhip." The era of Danaus is, therefore, the era of the ſhip; being the preciſe time when ſome model of this ſacred veſſel was introduced, and the rites alſo and myſteries with which it was attended. The 50 daughters of Danaus were 50 prieſteſſes of the Argo, who bore the ſacred veſſel on feſtivals. In Egypt there was a temple, called Ca Nobus, erected to the god of ſeas; to whom the element of water in general was ſacred. Throughout the whole hiſtory of Danaus and his daughters, ſays Bryant, there will be found alluſions to the rites of this god. The Danaides are ſaid to have been ſent in queſt of water; to have brought water to Argos; to have invented υδριαι, or veſſels for water; and laſtly, they were ſuppoſed to have been doomed in the ſhades below to draw water in buckets, which were full of holes. Every circumſtance of this hiſtory, Mr. Bryant imagines, is deduced from Egypt. The natives of that country were very aſſiduous in conveying water from one place to another. They had likewiſe particular jars, which were ſacred to the god, whom the Greeks called Canobus; and were formed with a repreſentation of him. Theſe canobic veſſels were ſometimes made of porous ſtone; at other times of earth manufactured in ſuch a manner as to have ſmall holes in the bottom; through which they uſed to filter the water of the Nile, when it was either turbid or ſaline. This practice of filling veſſels which could not hold the water put into them, ſeemed ſuch a paradox to the Grecians, that when they came to conſign ſome of their prieſts and deities to the infernal manſions, they made this the particular puniſhment of the Danaides, on account of their cruelty. Anal. Anc. Mythol. vol. ii.

The Danaides are ſometimes alſo called Belides, from their father, who was the ſon of the Egyptian Belius. Hyginus has preſerved the names of forty-ſeven of them.

DANAPRIS, in *Ancient Geography*, a river of Sarmatia, the ſame with Boryſthenes.

DANARAKIE, in *Geography*, a town of Perſia, in the province of Irak; 60 miles E. of Iſpahan.

DANASLU, in *Ancient Geography*, a name given by Jornandes to a river of Sarmatia; the Tyras of the ancients, and the Nieſter or Dnieſter of the moderns. It is called Danaſtus by Ammianus Marcellinus.

DANATA, a name given by Ptolemy to a town of Serica, between Abrogana and Oroſana.

DANBURY, in *Geography*, a town of America, in the ſtate of New Hampſhire, and county of Grafton; containing 165 inhabitants.—Alſo, a poſt-town in the county of Fairfield, in Connecticut; ſettled in 1687, and containing 2 churches, a court-houſe, and about 60 dwelling-houſes. On its ſmall ſtreams are iron-works, and ſeveral mills. It lies about 70 miles N.E. of New York city, and 33 N.W. by W. of New Haven. It has 3180 inhabitants.

DANBY, a poſt-town in Rutland county, Vermont, E. of Pawlet, containing 1487 inhabitants; 32 miles N. of Bennington.

DANCALI, a ſmall kingdom of Africa, on the coaſt of the Red Sea, reaching to the frontiers of Abyſſinia. It is bounded on the eaſt at Azab, by part of the kingdom of Adel, and the Myrrh country. This is a low, ſandy diſtrict, lying on the Red Sea, juſt where the coaſt, after bearing a little to the eaſt of north from Suez to Dancali, makes an elbow, and ſtretches nearly eaſt, as far as the Straits of Babelmandel. It has the mines of foſſile-ſalt immediately on the N. and N. W., a deſert part of the province of Dawaro to the S., and the ſea on the N. It has no port, excepting a ſpacious bay, with tolerable anchorage, called "the bay of Bilur," in lat. 13° 3′. and corruptly, the bay of Bayloul. The king is a Mahometan, as are all his ſubjects, who are called "Taltal;" they are all black, and ſome of them woolly-headed; a circumſtance which ariſes from a mixture with the Abyſſinians, whoſe hair is long. There are only two ſmall rivers of freſh water in the whole kingdom; and theſe, in the hot ſeaſon, are not viſible above the ground, but are ſwallowed up in the ſand, ſo that they are to be dug for when water is wanted. In the rainy ſeaſon they are ſwollen by rain falling from the ſides of the mountains, and from the high lands of Abyſſinia, and then only run with a current into the ſea. The reſt of the water in the country is ſalt or brackiſh, and unfit for uſe. Whenever theſe fail, they are obliged to ſeek, far off in the rainy frontiers of Abyſſinia, water for themſelves, and paſture for their miſerable goats and ſheep. When the Indian trade flouriſhed, this prince's revenue aroſe chiefly from furniſhing camels for the tranſport of merchandize to all parts of Africa. Their commerce is now confined to the carrying of bricks of ſolid or foſſile-ſalt, dug from pits in their own country, which, in Abyſſinia, paſs inſtead of ſilver currency; theſe they deliver at the neareſt market in the high land, at a very moderate profit, after having carried them from the ſea-ſide through the dry and burning deſerts of their own country, at the great riſk of being murdered by Galla. Bruce's Travels into Abyſſinia, vol. ii. and iii.

DANCE, an agreeable motion of the body, adjuſted by art, to the meaſures of a piece of muſic, either ſung or played.

The word is French, *dance*, formed of the German *danz*, or *tantz*, which ſignifies the ſame thing. Bochart derives it from the Arabic *tanza*, and Guichart from the Hebrew דוץ *douts*, which have all the ſame ſignification. Salmaſius derives the French, dancer, to dance, from the Latin denſare, to thicken; as holding it a practice among the ancient fullers to leap and dance as they fulled their cloths.

Some diſtinguiſh the high dance, conſiſting of capers, gambades, &c. from the low dance, which is terra à terra or cloſe to the ground.

In the carouſal of king Louis XIII. there were dances of horſes. The invention of ſuch dances is attributed to the Sybarites.

Dancing has always been in uſe among all nations, both civilized and barbarous; though held in eſteem among ſome, and in contempt among others. Of itſelf, no doubt, dancing is harmleſs. There is a time, ſays the preacher to dance; and ſometimes it is even made an act of religion. Thus David danced before the ark, to honour God, and expreſs his exceſs of joy for its return into the city of Sion. The daughters of Shiloh are likewiſe ſaid to have danced in a yearly feaſt of the Lord. Judges, chap. xxi. And we find many references to this practice in the religious ſolemnities of the Jews. From them it paſſed to the Egyptians, and afterwards to the Greeks and Romans, with whom it was a principal part of the worſhip of their falſe Gods. It afterwards was adopted in many pagan nations; and Chriſtians in popiſh countries celebrated certain feſtivals, particularly thoſe of the ſacrament, and paſſion of our Lord, with dancing. Socrates learnt to dance of Aſpaſia. And the people of Crete and Sparta went to the attack dancing. On the other hand, Cicero reproaches Galbinius, a conſular man, with having danced. Tiberius expelled the dancers out of Rome: and Domitian excluded ſeveral members from the ſenate, for having danced. Caſtor and Pollux are ſaid to be the firſt who taught the art of dancing; and that to the Lacedæmonians: though others attribute the invention to Minerva, who, they ſay, danced for joy after the defeat of the giants.

The ancients had three kinds of dances, called bacchic; the firſt grave, called emmelia, anſwering to our low dances and pavanes. The ſecond gay, called cordax, anſwering to our courants, galliards, gavots, and vaults. The third, called ſiccinis, was a mixture of gravity and gaiety. Neoptolemus, ſon of Achilles, taught the Cretans a new ſort of dance, called Pyrrhica, or the armed dance; to be uſed in going to war: though, according to mythologiſts, the Curetes firſt invented this dance, to amuſe and divert the infant Jupiter, and to drown his cries with the noiſe and claſh of their ſwords, beating againſt their bucklers.

Diodorus Siculus, in the fourth book of his Bibliotheca, aſſures us, that Cybele, daughter of Menoes, king of Phrygia, and Dindymenis his wife, invented divers things, and, among others, the flageolet of ſeveral pipes, dancing, the tabor, and the cymbal. Numa, it is certain, inſtituted a ſort of dance for the ſalii, prieſts of Mars, who made uſe of weapons therein. From theſe dances were compoſed another ſort, called ſaltatio mimicorum, or the buffoons' dance; wherein the dancers were dreſſed in little corſlets, with gilt morions, and had bells on their legs, and ſwords and bucklers in their hands. Lucian has an expreſs treatiſe, and Julius Pollux a chapter, on this head; Athenæus, Cælius Rhodiginus, and Scaliger, alſo make mention of this dance.

It is not many years ago ſince Thoinot Arbeau, a dancing-maſter of Paris, gave an orcheſography, wherein all the ſteps and motions of a dance are written, or noted down; as the ſounds of a ſong are ſcored in muſic. Though the famous Beauchamp has ſome pretenſions to be the inventor of this ſecret, and accordingly procured an arret in his favour.

Dancing is uſually an effect and indication of joy among moſt nations: though M. Palleprat aſſures us, that there are people in South America, who dance to ſhew their ſorrow; and it likewiſe made a part of the funeral ſolemnities of the ancients.

Dancing is ſo neceſſarily connected with muſic, that in treating one art we cannot avoid alluſions to the other. What is it that excites dancing? Muſic. What is it that regulates the ſteps of the dance? Muſic. What is it that exhilarates and keeps off fatigue, but muſic? One of the moſt ancient proverbs in our language ſays; "No longer pipe, no longer dance," a truiſm which Ray has recorded among our national apophthegms.

From the ſocial and ruſtic dance of our peaſants and domeſtics to the ſublime ballet heroique, muſic is called in to animate and enliven the one, and to give grace and dignity to the other. No muſic can boaſt a ſuperior longevity to our country dances. No muſic is more accented, more impreſſive, and more varied in its meaſures, than that of the grand ballets, which of late years have been performed at the opera.

Muſic and dancing are frequent rivals; but as they cannot ſubſiſt without each other, their little jealouſies never come to an open quarrel.

Much has been written concerning the antiquity of this art, particularly in France, the reſidence of all the divinities who preſide over it. But Pere Meneſtrier, M. Cahuſac, and the celebrated ballet-maſter, Noverre, have nearly exhauſted the ſubject. Mademoiſelle Heynel, and the family of Veſtris, have left impreſſions of their ſuperior talents that will never be obliterated by the natives, nor will foreigners or poſterity be ſuffered to remain ignorant of their ſuperior worth, by hiſtorians and men of letters; any more than the readers of the reign of Auguſtus will be allowed to remain ignorant of the pantomimical powers of a Pylades or a Bathyllus.

Muſic, Lucian ſays, is attendant on the art of dancing, and ſubſervient to it. They are more reciprocally uſeful to each other, perhaps, than muſic and poetry; but muſic has its peculiar charms totally independent of both. Modern poetry of various kinds can delight without muſic, but melody is the ſoul of ſongs, without which few would find readers; and dancing, without muſic, would be heavy work, and to a ſpectator excite no other idea than the freaks of inſanity.

Dancing was probably at firſt no more than geſticulation, and moving gracefully in a proceſſion: a natural pantomime; and it has often been ſtyled by philoſophers, the art of geſticulation; and though at firſt natural and ſpontaneous, theſe geſtures were at length poliſhed and refined into rule; but it ſeems as if the firſt dances were religious, and hymns the firſt ſongs. Theſe were the germs of the two arts.

With the ancient Hebrews, as the ſacred writings inform us, dancing made a part of the celebration of all great events. David danced before the ark. In Egypt dancing was a principal part of the religious rites of the prieſthood; and it was in imitation of them that the children of Iſrael danced round the golden calf in the deſert. As the Greeks had their mythology from Egypt, Orpheus who travelled thither for knowledge, is ſuppoſed to have introduced into his country feſtal ceremonies ſimilar to thoſe of Egypt, in all which dance and ſong prevailed. The ingenuity and elegant taſte of the Greeks ſoon improved, refined, and poliſhed theſe ſacred ceremonies, which were adopted by the greateſt part of the civilized world; particularly by the Romans, who were original and ſuperior in nothing but the art of war, and in plundering, ſlaughtering, and enſlaving mankind.

Theſe were the religious dances of Paganiſm: but as a new religion is generally a reform of one more ancient, as the

Grecian

Grecian of the Egyptian; the Roman of the Grecian; the Chriſtian of the Jewiſh, &c., many forms and ceremonies to which the people have been long accuſtomed are neceſſarily retained; and among theſe the ſolemn dances of the Hebrews and Romans, on great feſtivals and celebrations, were admitted by the primitive Chriſtians; in which even the biſhops and dignified clergy, according to Scaliger and Pere Meneſtrier, were performers; and diſpoſitions were made in the firſt temples that were erected after Chriſtianity was firmly eſtabliſhed by Conſtantine, for theſe ſacred dances. Scaliger ſays, that the firſt biſhops were called *Præſules* in the Latin tongue, for no other reaſon than that they led off the ſolemn dance in great feſtivals: and Meneſtrier (Traité des Ballets, 1682) ſays, that he had ſeen the canons and choriſters, on Whitſunday, take each other by the hand and dance while they ſung hymns of jubilation. (And he has pointed out ſeveral ancient churches, ſtill ſubſiſting, in which the choir was conſtructed in a theatrical form.) After ſpeaking of the religious dances of the Hebrews and Pagans, this writer obſerves, that the name of choir is ſtill retained in our churches for that part of a cathedral where the canons and prieſts ſing and perform the ceremonies of religion. The word comes from χορος a *dance*, or a *company of dancers*. The derivation is remarkable, and not one of thoſe that can be ſuſpected of proceeding from fancy, and accidental ſimilitude of ſound. One of the acceptations of the term χορος, given by Suidas, is—το συςημα των ἐν ταις ἐκκλησιαις ᾀδοντων—a *company of ſingers in a church*; that is, a *choir*. It ſeems likewiſe to have been ſometimes uſed, like our word *choir*, in the *local* ſenſe: χορος, ſays Suidas, και οἱ χορευται, και ὁ τοπος, &c. that is, *dancers*, and *the place* in *which* they *danced*. It is ſo uſed by Homer, Od. viii. 260. Λειηναν δε χορον.—They made ſmooth, or level, the *place* appointed for *dancing*. The choir was formerly ſeparated from the altar, and elevated in the form of a theatre, encloſed on all ſides with a baluſtrade. It had a pulpit on each ſide, in which the epiſtle and goſpel were ſung, as may ſtill be ſeen at Rome in the churches of St. Clement and St. Pancratius, the only two that remain in this antique form. Spain, continnues he, has preſerved in the church, and in ſolemn proceſſions, the uſe of dancing to this day; and has theatric repreſentations made expreſsly for great feſtivals, which are called *Autes Sacramentales*. France ſeems to have had the ſame cuſtom till the twelfth century, when Odo, biſhop of Paris, in his ſynodical conſtitutions, expreſsly orders the prieſts of his dioceſe to aboliſh it in the church, cemeteries, and public proceſſions. Conſtitut. 36.

The deſcendants of the original inhabitants of our iſland, the Cambro-Britons, in our own memory, on Sundays, uſed to be played out of church by a fiddle, and to form a dance in the church-yard at the concluſion of the ſermon. Theſe could hardly be called religious dances, though in ſome meaſure connected with the ſervice of the church, where the people are aſſembled; but however harmleſs the practice may originally have been, it has, we believe, been totally diſcredited and aboliſhed by the diſſenters and methodiſts. In France, ſays M. Cahuſac, this ſimple and ruſtic amuſement, which ſeemed to imply gentle and cheerful manners, is now changed for a little wit and much corruption. (Traité Hiſtorique de la danſe.)

On the ſtage, heroic and hiſtorical ballets ſeem very early to have been introduced at Athens, either as intermezzi or in the texture of the drama. The labyrinth of Crete, the battle of Theſeus and the Minotaur, and other well known and popular ſubjects, were repreſented in pantomime, without oral utterance. Proteus, of whom ſuch marvellous changes of figure are related, was only one of their dancers.

In this art, like all others, the Greeks were copied by the Romans.

Pylades, a native of Cilicia, and Bathyllus of Alexandria, carried the pantomimical art at Rome to ſuch perfection in the time of Auguſtus, that all other ſpectacles were neglected by the public. Theſe actors opened a theatre at firſt in partnerſhip; Pylades repreſented grave, tender, and pathetic ſubjects; Bathyllus, ſuch as were cheerful, gay, and jocoſe. But each reciprocally mortified by the applauſe acquired by the other, of which each thought himſelf ſeverally robbed, they ſeparated in a fit of jealouſy, and each ſetting up for himſelf, improved the art by opening different theatres, forming ſcholars, and exhibiting to ſpectators partial to the peculiar talents of each. The public took ſides, diſcuſſed and diſputed their ſeveral merits, and forgot the loſs of the republic and of liberty, to the great increaſe of political tranquillity, and eaſe of Auguſtus and his imperial government. Rome was divided into two factions, the Pyladians and Bathyllians, as France ſome years ago into Gluckiſts and Picciniſts. In the time of Nero, a dancer repreſented the labours of Hercules, traced, in a manner ſo true, all the different ſituations of this hero, that a king of Pontus who ſaw this exhibition for the firſt time, followed the geſtures of the actor ſo cloſely as to comprehend with facility every circumſtance, and was ſo delighted that he entreated the emperor, as a great favour, to let him take the dancer home with him; informing Nero, that he had barbarous neighbours, whoſe language no one underſtood, and who had never been able to learn his own, but he thought the geſticulations of this man would explain his wiſhes to them.

P. Meneſtrier, not a philoſopher, but a regular eccleſiaſtic, who lived under, and wrote for a religious prince (Louis XIV.), ſays, that dancing is in itſelf one of thoſe indifferent things of which the good or bad uſe may incline us to approve or condemn.

The ſages of antiquity regarded dancing as a uſeful bodily exerciſe, an inoffenſive relaxation, and as an efficacious preſervative againſt the diſorders of the mind. When the body is in motion, the mind repoſes itſelf. The figure, the ſteps, the movements of the dance, are equally amuſing to the dancer and the ſpectator. See BALLET and PANTOMIME.

The intimate connexion between muſic and dancing is ſuch as to require a ballet-maſter, not only to be a practical muſician, but a judge of compoſition; if not a compoſer himſelf he ſhould be able to ſuggeſt ſuch ſubjects to the maeſtro di cappella, as will expreſs his ideas, ſuit his principal ſubject, and paint the ſituations into which the ſeveral characters are thrown. Noverre thought that a ballet well compoſed wanted no recit, no words to explain its meaning. Singing and dancing together mutually weaken each other; and even St. Auguſtine, in ſpeaking of ballets, in the third century, complained of their monotony, and ſaid that they were obliged to place a crier at the ſide of the ſcene, to proclaim to the ſpectators what the dancers were about to repreſent. The recits, dialogues, and monologues in the ſplendid dances of Lulli's operas in the time of Louis XIV., Noverre cenſures. He puts great contempt upon mere dancing, and wants to reduce the whole art to pantomime, deſpiſing agility and feats of activity. "Les belles pirouettes, les beaux entrechats," and the remaining ſteadily for a conſiderable time, "ſur le petit point du pied, ſeem hors d'œuvres," in his ſyſtem.

As man had ſenſations before articulation and language; and tones of voice expreſſive of joy, ſorrow, pleaſure, and pain; ſo his features muſt have changed, and geſtures varied in theſe various ſituations. At all times, and in all countries, dancing has advanced towards perfection with the drama. The feaſt

of

of Flora, at the beginning of May, was more particularly celebrated by dancing than any other Pagan feſtival; and among Chriſtians the May-poles erected in our villages, adorned with garlands of real flowers, as well as artificial, around which our peaſants and domeſtics dance, are remains of the Pagan celebration of ſpring.

Domeſtic feſtivity on occaſion of the marriage of a child, the anniverſary of a parent's birth, the arrival of beloved and reſpected ſtrangers, checquered the monotony of ancient ſimplicity of manners.

Socrates himſelf learned late in life to dance of the beautiful and accompliſhed Aſpaſia; and Cato, with all his rigour and ſeverity of manners, diſdained not, at upwards of 60, occaſionally to practiſe what he had learned in his youth.

As there are few amuſements, however innocent in the beginning, while in the hands of the judicious, moral, and decorous members of ſociety, that do not degenerate into licentiouſneſs when imitated by the vulgar; ſo dancing among the Romans, when made a trade, and females were hired occaſionally to enliven domeſtic feſtivity and riotous joy by their talents, gave birth to diſſolute manners, and depravity.

But on ſolemn occaſions, as muſic had its mania, dancing was not confined to occaſions of mirth and joy; there were funeral dances at the interment of great perſonages. And the Spartans advanced to the enemy in a military ſtep, that was called the Phrygian dance.

After dancing had been incorporated in the drama of Athens, it became neceſſary for the ballet-maſter, according to Lucian, to be poſſeſſed of univerſal knowledge. Poetry was neceſſary to ornament, muſic to animate, geometry to regulate, and philoſophy to guide his compoſitions. Rhetoric was likewiſe required to enable him to expreſs and move the paſſions, painting to delineate attitudes, and ſculpture to form his figures. He ought to be equal to Apelles, and not inferior to Phidias. All times ſhould be preſent to his mind, but he ought moſt profoundly to ſtudy the emotions of the ſoul, in order to paint its operations by the movements of the body. His conceptions ſhould be eaſy and natural, his mind lively, his ear nice, judgment ſound, imagination fertile, taſte certain in ſelecting whatever is proper and neceſſary to his deſign. Theſe are rare but indiſpenſable qualities with which ancient hiſtory, or rather fable, will furniſh him materials for the moſt magnificent compoſitions.

He muſt, therefore, inform himſelf of every important event that has happened in the world, from its riſing out of chaos to the preſent time.

Lucian was born under Trajan, and ſurvived Marcus Aurelius. "Lucian," adds M. Cahuſac, "did not require too much of the ballet-maſters of his time; as at Rome all great ſubjects of tragedy and comedy were included in the circle of pantomime. The compoſers of ballets were there, at once poets, muſicians and actors; whereas in our time, the poet is ſeldom a muſician, the muſician never a poet, and the actor neither one nor the other."

In the time of Auguſtus, the two great actors and maſters of declamation, Roſcius and Æſop, were forgotten, and their talents replaced by thoſe of the two great maſters of pantomime, Pylades and Bathyllus. But this was not effected by mere dancing; ſteps, movements, attitudes and poſitions were no longer in queſtion: there reſulted from their performance an expreſſion ſo natural, images ſo reſembling, a pathos ſo touching, or a pleaſantry ſo agreeable, that the ſpectators thought they heard what they ſaw. Geſtures alone ſupplied the ſweetneſs of voice, the energy of diſcourſe, and the charms of poetry. Hanc partem, &c. Caſſiodorus Var. i. 20.

As literature and all the arts partook of the declenſion of the Roman empire, dancing and pantomime could not eſcape decay. Rome, ſubdued by barbarians, plunged into ignorance: and darkneſs covered the reſt of the civilized world. Warriors were left, but the culture of the human mind was ſo totally neglected, as to convert into a deſert and a wilderneſs its moſt poliſhed and fertile provinces.

Few attempts were made to revive the arts in Italy till the 15th century; and thoſe connected with the drama were clumſy and awkward. Poetry and painting, indeed, had made great ſtrides towards perfection before dramatic muſic and dancing had awakened any public intereſt. Dancing made no part of the firſt Italian operas; but in the ſecond ſpecies of melo-drama in Italy, authors tried to unite all the charms of muſic and poetry with the wonders of machinery; and ſoon after the opera was embelliſhed with ballets hiſtoriques, fabuleux, and poetiques.

There were ballets poetiques, allegoriques, boûffons, at the court of Turin, to celebrate the nuptials of illuſtrious perſonages.

In France, balls, maſquerades, and ballets, after the accident which happened to Henry II., in 1559, ſupplied the place of carouſals, tilts, and tournaments.

M. Cahuſac, in his "Traité Hiſtorique de la Danſe," is miſtaken in ſpeaking of the firſt opera, when he ſays, (tome ii. p. 82.) "Ce ſpectacle etoit ſans danſe;" for it appears in the ſcore, printed in 1600, that the choruſes were ſung and danced at the ſame time, like thoſe on the French ſtage in the operas of Lulli. But in the firſt operas it was certainly the intention of their legiſlators, to favour poetry, and conſtitute her miſtreſs of the feaſt; and it was a long time ere muſic abſolutely took the lead. Dancing ſtept into importance only during the laſt century; but rarely in that preceding it.

There were analogous dances in the firſt oratorio at Rome: Dell' anima e corpo, performed in the church of La Vallicella. In the inſtructions for performing this oratorio, it is ſaid, "The performance may be finiſhed with or without a dance. If without, the laſt chorus is to be doubled in all its parts, vocal and inſtrumental; but, if a dance is preferred, a verſe beginning thus: *Chioſtri altiſſimi, e ſtellati,* is to be ſung, accompanied ſedately and reverentially by the dance. Theſe ſhall ſucceed other grave ſteps and figures of the ſolemn kind. During the ritornels the four principal dancers are to perform a ballet, *ſaltato con capriole,* 'enlivened with capers or *entrechats,*' without ſinging. And thus, after each ſtanza, always varying the ſteps of the dance; and the four principal dancers may ſometimes uſe the *galiard,* ſometimes the *canary,* and ſometimes the *courant* ſtep, which will do very well in the ritornels."

Dr. D'Avenant's dramatic operas, in 1671, were all ſet off with the moſt expenſive decorations of ſcenes and habits, and with the beſt voices and dances.

Dryden's definition of an opera, is, "a fiction, repreſented by vocal and inſtrumental muſic, adorned with ſcenes, machines, and dances."

In July 1697, Italian intermezzi, or interludes and mimical entertainments of ſinging and dancing, were performed at York Buildings.

Little mention is made of dancing in the firſt Italian operas performed in England. At the end of Handel's *amadigé,* there was a dance to the melody of the coro finale, 1715. No ballet-maſter, dance, or dancers, are mentioned after the dramatis perſonæ of any one opera ſet by Handel; poetry, compoſition and ſinging, and a complete orcheſtra, ſeem to have ſatisfied the public, without doubling the expence

expence of the performance in ſupport of an additional art.

It was during the regency of lord Middleſex, that a regular ballet maſter, principal dancers, and figuranti of both ſexes, were taken into ſalary. Before that period we have heard of individual dancers of great abilities and attractions: ſuch as miſs Saintlow, a Camargo, a Barberini, a Sallé, the two Pauſſans, the Aurettis, &c. &c.; but ballets heroïques, ballets hiſtoriques, ballets allegoriques, &c. ſeem to have had no exiſtence in this country till about the middle of the laſt century.

The French ſeem to have been the firſt in modern times to introduce ballets analogues in their muſical dramas. Thoſe in all operas written by Luinault and ſet by Lulli, are of that kind. The Italians, not inſenſible of their ſuperiority to all other countries in whatever concerns the fine arts in general, and who are jealous of French pretenſions to rivality, as the French are envious of their claims to preeminence, frankly allow them the palm in dancing. All the Italian writers on the drama, particularly the muſical, recommend the doctrines of Cahuſac and Noverre to the conſideration and practice of their ballet-maſters.

Algarotti, in his Eſſay on the Opera, addreſſed to the firſt Mr. Pitt, 1762, ſays, that though his countrymen have compoſed and executed ſome comic dances, of which the pantomime would have done honour to Pylades and Bathyllus; in ſerious and heroic ſubjects the Italians, and all nations, muſt ſtrike to the French, who ſeem by nature and cultivation as much formed for excelling in this art as the Italians in muſic. Dances, analogous, and incorporated in the drama in which they are performed, at preſent, ſeem preferred in France to all others; but where they are diſtinct, and only performed between the acts, a groteſque and comic dance ſhould not, in a ſerious drama, counteract the labours of the poet and performer, in exciting that pity and terror, which Ariſtotle makes the conſtituent parts of a tragedy. But even comic dances in a theatre ſhould have ſome meaning, ſomething to intereſt, beſides capering and feats of activity. Such ſhould have a plot, its intricacies and dénouement; and in theſe dances, as well as the heroic, the French incline much more to pantomime, in intelligent and eloquent geſtures performed by the hands and features, than by the feet. In Ricoboni's Hiſtory of the Stage, dancing is never mentioned; and Algarotti ſays, "it never was a conſtituent part of the drama, but is always foreign to the buſineſs, and very often repugnant to it. If the ſcene of action be in Rome, the dance is often in Holland or China; and if the opera is ſerious, the dance is ſure to be comic."

DANCE *of St. Vitus*. See VITUS.

DANCE, *Country*. See COUNTRY-*Dance*.

DANCER, *Rope*, *Schœnobates*. Groddeck, profeſſor of philoſophy at Dantzic, has publiſhed a diſſertation on rope-dancers, "De Funambulis," full of learning, and an uncommon knowledge of antiquity. He defines a rope-dancer, a perſon who walks on a thick rope faſtened to two oppoſite poſts; which is preciſely what is expreſſed by the Latin word Funambulus. But our rope-dancers do more; for they not only walk, but dance and leap upon the rope.

The ancients, it is certain, had their rope-dancers as well as we: witneſs the Greek words, neurobates, and ſchœnobates; as well as the Latin funambulus, which everywhere occur. They had likewiſe the cremnobates and oribates, that is, people who walked on the brinks of precipices. Nay more, Suetonius, in Galba, cap. 6. Seneca in his eighty-firſt epiſtle, and Pliny, lib. viii. cap. 2. make mention of elephants that were taught to walk on the rope. This they did both backwards and forwards, as well as up and down; and this feat Galba firſt cauſed to be exhibited to the Roman people. After this, ſuch was the confidence repoſed in the dexterity of the animal, that a perſon ſat upon an elephant's back while he walked acroſs the theatre upon a rope, extended from the one ſide to the other. Lipſius, who has collected the teſtimonies, thinks they are ſo ſtrong, that they cannot be doubted. "Epiſtolarum ſelectarum centuria." Antwerp. 1605. 4to. Suet. Vit. Galba. Seneca Epiſt. 26. Dio Caſſius. In the 13th century ſome ventured to ride a horſe upon a rope.

Mr. Groddeck, coming from the hiſtorical to the moral conſideration, maintains that the profeſſion of a rope dancer is not lawful; that the profeſſors are infamous, and their art of no uſe to ſociety; that they expoſe their bodies to very great dangers; and that they ought not to be tolerated in a well-regulated ſtate. But, coming afterwards to temper the ſeverity of his morals, he allows that there are ſometimes reaſons for admitting them; that the people muſt have ſhews; that one of the ſecrets of government is to furniſh them therewith, &c.

The ancient rope-dancers had four ſeveral ways of exerciſing their art; the firſt vaulted, or turned round the rope, like a wheel round its axis, and there hung by the heels or the neck. The ſecond flew, or ſlid, from above, downwards, reſting on their ſtomachs, with the arms and legs extended. The third run along a rope ſtretched in a right line, or up and down. Laſtly, the fourth not only walked on a rope, but made ſurpriſing leaps and turns thereon. But it is needleſs to recount the various feats of this kind that are exhibited in our places of public amuſement.

DANCERIES, an old French term for country-dance tunes. Jean d'Etrées, a performer on the hautbois in the ſervice of Charles IX., publiſhed at Paris, in 1564, four books of Danceries, firſt writing down the common lively tunes, which, till then, had been probably learned by the ear, and played by memory, about the ſeveral countries ſpecified in the title. The editor of theſe books tells us, that they contained Les chant des branles communs, gais, de champagne, de Bourgogne, de Poitou, d'Ecoſſe, de Malte, des Sabots, de la Guerre, & autres gaillardes, ballets, voltes, baſſes dances, hauberrois, allemandes. Printed at Paris, 1564.

DANCERS, in *Eccleſiaſtical Hiſtory*, a ſect that ſprung up at Aix-la-Chapelle in 1373, and ſpread through Flanders. Perſons of both ſexes were ſuddenly ſeized with dancing fits, and continued them, with extreme violence, till they were quite exhauſted; and at theſe times they pretended to receive wonderful viſions. Like the Flagellants, the dancers wandered about from place to place, had recourſe to begging for their ſubſiſtence, treated with the utmoſt contempt both the prieſthood, and the public rites and worſhip of the church, and held ſecret aſſemblies. This new kind of phrenzy was regarded by the ignorant clergy of that age as the work of evil dæmons, who poſſeſſed, as they thought, this dancing tribe. Accordingly the prieſts of Liege endeavoured to caſt out the devils, which rendered theſe fanatics ſo merry, by ſinging hymns and applying fumigations of incenſe; and they gravely tell us, that the evil ſpirit was entirely vanquiſhed by theſe powerful charms. The French prophets, or convulſioniſts, in later times, and ſome wild enthuſiaſts in America, and in our own country, under the appellation of *ſhakers*, *jumpers*, &c. reſembled theſe more ancient religious dancers.

DANCETTE', in *Heraldry*, is when the out-line of any bordure, or ordinary, is indented very largely; the largeneſs

of the indentures being the only thing that diſtinguiſhes it from indented.

There is alſo a bearing of a bend, called *double dancetté*; thus, he beareth azure, a bend *double dancetté* argent.

DANCHE', or *Denché*, the ſame with indented; or, as others will have it, with *dancetté*.

DANCHET, Antony, in *Biography*, a French poet, and man of letters, was born at Riom in 1671. His parents were of low rank, but by the exertions of his friends he was enabled to acquire a good education, and was at length admitted ſtudent in the college of Louis le Grand at the time of taking Mons and Nice. He wrote a Latin poem upon theſe victories, which was printed while he was ſtill a collegian. He was afterwards choſen rhetorical profeſſor in the college of Chartres, which poſt he occupied four years. In after-life he applied himſelf chiefly to poetry, and the belles lettres, was admitted a member of the French academies, and had a place aſſigned him in the royal library. He died in 1748. He had no claims to be ranked in the firſt claſs of literary excellence, but his works obtained for him a conſiderable ſhare of reputation; they were collected and publiſhed in 1751 in four volumes 8vo. As a man he was highly eſteemed for the qualities of his mind and the mildneſs of his temper; he was ſincere, upright, and diſintereſted, and was an enemy to every ſpecies of ſatire and calumny, weapons too frequently uſed by poets and men of genius. Moreri.

DANCKERT, or Danckerts, Cornelius, a deſigner and engraver, born at Amſterdam in 1561. There were ſeveral engravers of this name, and moſt probably of this family, of which Cornelius may be conſidered the head. He eſtabliſhed himſelf at Antwerp as a print-ſeller; but he did not ſuffer this employment to engroſs his whole time, as he engraved many portraits, landſcapes, and hiſtorical pieces, as well from his own compoſitions as from the deſigns of Berghem, Rembrandt, and others. We ſhall only mention the following: Guſtavus Adolphus, king of Sweden, a large plate; Cornelius de Wit, in a battle, ditto; John Calvin, a large, oval plate. The following are from his own deſigns: the four Monarchies, Ninus, Cyrus, Alexander, and Cæſar; Figures on Horſeback, with emblematical devices, 4 plates, folio; the ſeven Wonders of the World, 7 plates, folio; the principal Subjects of the Old Teſtament, 100 ſmall prints, 4 on each plate; a ſet of Views in Holland, 6 plates. Huber.

Danckerts, Danckert, the ſon of Cornelius, was born at Antwerp, about the year 1600. He alſo engraved different ſubjects, as well from his own deſigns as from thoſe of other artiſts; and though his pieces are not ſo numerous as his father's, they ſurpaſs them in merit. Danckert combined the point and the graver with very great ſucceſs, and the pieces from Berghem and Wouvermanns, which he has wrought in this manner, are much eſteemed. We ſhall mention a few of his engravings: the Portrait of Charles II. king of England, folio; Venus and Cupid, aſleep, ſpied by a Satyr, folio, marked *D. Danckerts, exc.*; Pigeon-ſhooting and Stag-hunting, a pair, large plates, from Berghem, *Danckert Danckerts, fec. et exc.*; four large Landſcapes, from Berghem, lengthways; another ſet of four, of a ſmaller ſize, from the ſame maſter; another ſet of ſix, ſtill ſmaller, from the ſame. Huber.

Danckerts, John, a deſigner and engraver, who, about the year 1654, ſettled at Amſterdam; but being invited into England, he went to London, where he deſigned for the Engliſh Juvenal, the plates engraved by Hollar. This artiſt alſo engraved ſome plates. We ſhall only mention the following: Venus lying upon a Couch, from Titian, *Joh. Danckerts, sc. aq. forti* 1657.; Merchants ſhipping their Goods, *Joh. Danckerts sc.* Huber.

Danckerts, Henry, brother to the above, was alſo bred an engraver, but afterwards became a landſcape-painter. He was born at the Hague, but at an early age travelled into Italy, from whence he came to England. Here he enjoyed the favour of Charles II. who employed him to draw views of the Britiſh ſea-ports, and royal palaces. During the diſturbances which preceded the abdication of James II. (Walpole, by a ſtrange anachroniſm, ſays, *in the time of the popiſh plot*), he quitted England for Amſterdam, where he died ſoon after. The landſcapes painted by this artiſt were numerous, and are chiefly to be found in England. Amongſt them are Views of Windſor, Plymouth, Penzance, &c. marked HDankers, F. 1678, 1679. He alſo engraved from Vandyk, Titian, Jacopo Palma, &c. Walpole. Huber.

Danckerts, Justus. This artiſt was of the ſame family as the former. He was a deſigner, engraver, and print-ſeller, and reſided in Amſterdam. The following plates bear his name: the Portrait of Caſimir, king of Poland; a ditto of William III., prince of Orange; the Harbours of Amſterdam, a ſet of 7 pieces. Huber.

Danckerts de Ry, Cornelius. The circumſtance of both Milizia and Heinecken dating the birth of this architect in 1561, and ſaying that he was born in Amſterdam (the very time and place of the birth of Cornelius Danckerts mentioned above), leads us to ſuſpect ſome chronological error, if not, indeed, that theſe two artiſts were one and the ſame perſon. Cornelius was originally a ſtone-maſon, but afterwards applied himſelf to architecture. He conſtructed in the city of Amſterdam many public and private buildings, highly creditable to his talents on account of their beauty and convenience, and, amongſt others, three of the principal churches, the exchange, and the gate which leads to Haarlem, the moſt beautiful of the city.

Cornelius had a ſon named Peter, who was born at Amſterdam in 1605, and afterwards became painter to Uladiſlaus, king of Poland. Milizia, Mem. degli Architetti.

DANCORITON, in *Ancient Geography*, a town of Illyria, in Liburnia, ſuppoſed to be the ſame that is called by Pliny and Ptolemy Corinium.

DANCRETA, in *Botany*, a name given by the people of Guinea, to a plant which they uſe in diſorders of the head, boiling it in water, and uſing the decoction in the way of fomentation. It is a ſpecies of bindweed, and is called by Petiver, convolvulus quinque foliis Guinenſis foliis non ſerratis, or the five-leaved Guinea bindweed, with leaves not ſerrated. Caſpar Bauhine, in his Prodromus, deſcribes a ſpecies of bindweed growing in Egypt, which exactly agrees with this in all particulars, except that it is finely ſerrated all round the edges of the leaves. Phil. Tranſ. N° 292.

DANDA, in *Geography*, a river of Africa, which ſeparates Kongo Proper from the kingdom of Angola. It is a conſiderable river, and navigable quite up to the town of Icoa; that is, about 30 leagues and upwards. This river gives its name to the province through which it paſſes, and the countries of which it fertilizes; but without cauſing ſuch deſtructive inundations as the Zair. Its navigation, though not difficult or dangerous, is ſubject, however, to the interruption and moleſtation of the numerous ſwarms of crocodiles, ſea-horſes and monſtrous ſerpents, which infeſt it, and make a dreadful havoc among thoſe who frequent it in canoes and other ſmall veſſels. Its courſe is from ſouth-eaſt to north-weſt; during which it receives the Lucale, and ſome other leſs conſiderable ſtreams. This river, and alſo the Bengo and Lucale, are ſuppoſed to ſpring from a lake among the high

high mountains in the eaſt. On the northern ſhore of its mouth is a fort, called "Danda Capitantria," which ſerves as a guard of the frontiers between Kongo and Angola.

DANDACA, in *Ancient Geography*, *Eſki-Foros*, a town of the Cherſoneſus Taurica, upon the moſt weſterly point of the peninſula, W.N.W. of Cherſoneſus.

DANDAGULA, a town of India, on this ſide of the Ganges, in the vicinity of the promontory of Calingon.

DANDAR, in *Geography*, a circar of Hindooſtan, in the country of Guzerat, on the banks of the Puddar, S.W. of Oudipour.

DANDARICA, in *Ancient Geography*, a kingdom ſituated S.E. of the Palus Mæotides, which was traverſed by the river Hypanis.

DANDARII, a people of Aſia, who inhabited the vicinity of mount Caucaſus, Steph. Byz. Strabo places them to the ſouth of the Palus Mæotides. Theſe people occupied the northern coaſt of the Euxine ſea, at the angle of the eaſtern part. It is mentioned by Ammianus Marcellinus.

DANDAXANA, a town of Cappadocia, in the Melitené territory, towards the N.W. of Arca.

DANDELION, in *Botany*. See LEONTODON.

DANDELION, in *Agriculture*, is the name of a very troubleſome weed, the *leontodon officinale*, which is well known as infeſting meadows and other grounds, and which ſpreads greatly where the flowers are ſuffered to perfect their ſeeds, which from being light and downy, are readily capable of being blown about by the wind. It is a weed which ſhould of courſe be extirpated as ſoon as poſſible after it appears, in order to prevent its ſeeding.

DANDINI, CESARE, in *Biography*, a painter of ſome eminence, who was born at Florence, about the year 1595. At the age of 12 he was placed under the tuition of Franceſco Curado, with whom he ſtaid three years: he then became the diſciple of Chriſtofano Allori, and afterwards of Dominico Paſſignano, who took him to Piſa, where he availed himſelf of his aſſiſtance in a conſiderable work he was there employed to execute. On his return, Ceſare was ſent by his father to complete his ſtudies at Rome. There he remained ſome years, and upon his return to Florence enjoyed the reputation of an experienced and correct painter. His works, which much reſemble thoſe of Paſſignano, are by no means uncommon in the churches and palaces of Florence; but his chef-d'ouvre is an altar piece at Ancona, repreſenting St. Carlo and other ſaints, which is judiciouſly compoſed, executed with a maſterly pencil, and well preſerved. This artiſt died at the place of his nativity in 1658. Baldinucci.

DANDINI, VINCENZIO, brother to the laſt-mentioned artiſt, was born at Florence, in 1607. After having been taught the firſt rudiments of his art in the ſchool of Ceſare, he went to Rome, where he ſtudied ſome time under Pietro da Cortona, and copied with the greateſt aſſiduity the maſterpieces of art which adorn (or then adorned) the palaces and temples of that city. Vincenzio was conſidered one of the beſt of Cortona's ſcholars, and met with ample encouragement from the grand duke, as well as from private perſons, on his return to Florence. He painted a beautiful ceiling, in which he repreſented Aurora attended by the hours, at the villa of Poggio Imperiale; and a large picture of the Sacrifice of Niobe, at that of Petraja. One of his beſt altar-pieces, which are frequent at Florence, is the Conception of the Virgin, in the church of Ogniſanti. Lanzi. Storia Pitt.

DANDINI, PIETRO, the ſon and diſciple of Vincenzio, was born at Florence, in 1646. The ſtyle of Pietro Dandini, though founded on that of his father, ſoon degenerated into that manneriſm which is frequently the reſult of facility of execution too ſoon acquired. Although he poſſeſſed, in the opinion of ſome writers, talents even ſuperior to thoſe of his uncle and father, his deſire of gain ſo overbalanced the reſpect he owed his reputation, that his bold pencil generally contented itſelf to paint the unſtudied and ill-digeſted compoſitions of an hour. Sometimes, however, when he was well paid, he ſhewed his abilities; as in a cupola at the church of S. Maria Maddalena, at Florence, as well as in ſome freſcoes in the ducal palace and villas. In the public palace at Piſa, is an extenſive compoſition by this artiſt, repreſenting the taking of Jeruſalem, which likewiſe evinces great talent. One of his beſt altar-pieces is in the church of the Servi at Florence; it repreſents Beato Piccolomini in the act of ſaying maſs. Pietro Dandini died in 1712, leaving a ſon named Ottaviano, who followed the footſteps of his father in ſeveral public works which he executed in Florence. Lanzi.

DANDOLO, HENRY, in *Biography*, one of the moſt illuſtrious of the doges of Venice. In early life he had been ambaſſador at the court of Conſtantinople, where he maintained the rights of his country with ſpirit and dignity. It was not till he had reached his eighty-fourth year that he was advanced to the high honour of doge; but he retained his faculties at that period with ſo much vigour, that the events of his government were among the principal cauſes of the greatneſs of Venice. The republic, at the commencement of his adminiſtration, was engaged in war with the Piſans; but the deciſive meaſures of Dandolo ſoon brought it to a termination. He humbled alſo the Veroneſe; and on the formation of the league for the fourth cruſade, under Baldwin earl of Flanders, application was made to Venice for its aſſiſtance. Dandolo received their deputies favourably, and pleaded their cauſe with ſo much effect, that a treaty was formed in 1201 upon terms greatly to the advantage of the Venetians, who agreed to furniſh ſhips, proviſions, and a ſquadron of armed galleys. Hoſtilities were firſt directed againſt Zara, which was taken and diſmantled; and the conquerors proceeded to Conſtantinople, on the pretext of aiding Alexius Angelus to reſtore his father, the emperor Iſaac, who had been dethroned by his own brother. The ſpirited and venerable doge entered warmly into this meaſure, for the ſake of procuring to his country an acceſſion of commerce and dominion. The fleet arrived before Conſtantinople in June 1203, and the ſiege was ſoon begun. In this Dandolo took an active part. At the ſtorming of the city, he ſtood in a ſuit of complete armour, on the prow of his galley, with the great ſtandard of St. Mark diſplayed before him, commanded his men to row up to the walls, and was the firſt who leaped on ſhore. The walls and towers on that part were ſpeedily occupied by the Venetians, and the banner of the republic fixed upon them, when Dandolo was called away to the aſſiſtance of the French, who were ſurrounded by ſuperior numbers. The Greeks were ſoon repulſed, and the uſurper fled, leaving his capital to the invaders. Dandolo was afterwards nominated to the high office of emperor; but his great age, and the circumſtance of his ſituation as doge, rendered it impoſſible for him to accept the intended honour. The Venetians, however, ſhared the imperial dominions, and Dandolo was ſolemnly inveſted with the title of deſpot of Romania. He died at Conſtantinople, in the year 1205, at the great age of ninety-ſeven. Moreri.

DANDOLO, ANDREW, doge of Venice, and the hiſtorian of his country, was born about the year 1310. He diſtinguiſhed himſelf in early life by his attainments in literature, and was in 1344 elected doge. Under his government the military character of his country ranked very high, and its commerce was extended, particularly by a connection with Egypt, which Dandolo formed by menas of an embaſſy to the

the ſoldan, and the firſt Venetian ſhips ſailed to Alexandria in 1345. This new trade occaſioned a war between the republics of Genoa and Venice, which continued with various ſucceſs ſome years, and which gave riſe to a correſpondence between the doge, and the celebrated Petrarch. The poet was the friend and advocate of peace; the doge replied, and his anſwer is printed among the epiſtles of Petrarch. War was, however, continued, but it cauſed the death of Dandolo which happened in September 1354. He was highly eſteemed by his countrymen for learning, eloquence, courteſy, and patriotiſm. As an author he is diſtinguiſhed for his "Chronicle of Venice," which comprehends the hiſtory of the republic from its foundation to the year 1342; and to him has been aſcribed the compilation of the ſixth book of Venetian ſtatutes. His chronicle obtained conſiderable reputation for impartiality, and for the exhibition of authentic documents which the author produced to ſubſtantiate his facts. Modern Univer. Hiſt.

DANDRIDGE, in *Geography*, deriving its name from the maiden name of the wife of the preſident Waſhington, a poſt and county town of America, in the ſtate of Teneſſee, and county of Jefferſon; 565 miles W. of Waſhington.

DANDUTI, in *Ancient Geography*, a people of Germany, placed by Ptolemy in the neighbourhood of the Tarani, and W. of the Nerterani.

DANE, in *Geography*, a river of England in the county of Cheſter, which joins the Weever at Northwich.

DANEBROG, *Order of*, in *Heraldry*, was inſtituted by Wilderman II. king of Denmark, on St. Laurence's day, in the year 1219, in commemoration of a ſtandard which, as it is pretended, fell miraculouſly from heaven, and revived the courage of Wilderman's ſoldiers, ſo that they beat the Livonians in a battle, in which they were at that time engaged. This ſtandard, in which was ſeen a white croſs, was called, in the language of the country, "Danebrog," or "Danenburgh," *i. e.* the ſtrength of the Danes. Chriſtian V. in the year 1671, revived the order, which had fallen to decay. The badge of the order is "a croſs pattée enamelled white, charged with 11 diamonds." The collar worn on grand days, is "a chain, conſiſting of the letters W. C. alternately, and crowned with a regal crown of Denmark; between the letters a croſs enamelled white, in the C. a figure 5;" the firſt letter alluding to the inſtitutor, and the other to the reviver of the order; on other days the knights have the croſs tied to a white ribband edged red, worn ſcarfwiſe from right to left. The knights likewiſe have embroidered on their coats a ſilver ſtar, ſurmounted with a croſs argent, edged gules, and thus inſcribed, C. V. Restitutor.

DANEDI, Gioseffo, and Gio. Stefano, called likewiſe *Montalti*, in *Biography*, two painters, natives of Treviglio, a town in the ſtate of Milan, where they flouriſhed in the 17th century. They were both educated in the ſchool of Morazzone: the former, however, afterwards ſtudied with Guido Reni, whoſe ſtyle he ſought to imitate, as appears by his Murder of the Innocents, in the church of S. Sebaſtiano, at Milan. Stefano followed the precepts of Morazzone, though, after the example of his brother, he was deſirous to add ſomething of delicacy to the boldneſs and vigour, which characterize the works of his maſter. One of his beſt works is the Martyrdom of S. Giuſtina, in the church of S. Maria, in Pedone, at Milan, which is correctly deſigned, and exempt from that cold and languid tone of colour which too frequently pervades his works. Gio. Stefano died in 1689, at the age of 81. His brother died at the age of 70, but in what year is unknown. Lanzi.

DANEMORA. See Dannemora.

DANEGELT, or *Dane-geld*, from *Dane* and *gelt*, ſignifying in Dutch, *money*, an annual tax laid on our anceſtors, firſt of 1*s*. afterwards 2*s*. for every hide of land through the realm, for maintaining ſuch a number of forces as were thought ſufficient to clear the Britiſh ſeas of Daniſh pirates, which heretofore greatly annoyed our coaſts.

It was firſt impoſed as a ſtanding yearly tax on the whole nation, under king Ethelred, A. D. 991. That prince, ſays Camden, Britan. 142. much diſtreſſed by the continual invaſions of the Danes, to procure his peace, was compelled to charge his people with heavy taxes, called danegelt. At firſt they paid 10,000*l*. then 16,000*l*. then 24,000*l*. after that 36,000*l*. and laſtly, 48,000*l*. *per annum*.

Ethelred, in 1008, made a vigorous effort to free his people from this infamous tribute, by a general tax on all the land of the kingdom, for fitting out a fleet, which might effectually guard againſt the Danes.

It appears from records, that danegelt was levied in the reign of Edward the Confeſſor, not to be paid to the Danes, but to oppoſe their invaſions; and it ſeems to have been continued during the firſt eight years of that king, as a conſtant fund for his navy. We are told, however, that he took it off A. D. 1051, becauſe he ſaw the devil dance on a heap of the money collected by that tax; but Ingulphus, who mentions this ridiculous tale, only as a popular rumour, gives us a very good reaſon why the lands of the kingdom were then diſcharged of this burden, namely, there being a great famine that year which moved the king to remit it, out of charity to the poor. Yet it muſt be obſerved, that this *temporary* evil was no proper cauſe for aboliſhing a tax, which at other times might be neceſſary, to *all perpetuity*; and therefore lord Lyttelton much doubts the hiſtorian's exactneſs in ſaying it was ſo aboliſhed. Edward's ſucceſſor, Harold, drew together a fleet of 700 ſhips of war; and yet we do not find that danegelt, or other ſimilar impoſition, was levied by that prince. In the year 1083, or 1084, William the Conqueror, apprehending a great invaſion of England from Denmark and Flanders, revived danegelt, and advanced it to ſix ſhillings a hide; but its produce was little more than had been obtained from former danegelts. It is not certain, that danegelt, or, as the Saxon Chronicle terms it, "militare tributum," was even exacted by William Rufus. It appears by the "great roll," commonly called the fifth of king Stephen, but which Mr. Madox has demonſtrated to belong to the reign of Henry I. that it was collected ſix years together by that king, and accounted for in the ſame words that were wont to be uſed in accounting for the ſettled yearly revenue. Of Stephen's reign we have no rolls; but ſome hiſtories take notice of his levying of danegelt, which he had a good pretence to do, as he was in perpetual fear of invaſions from Normandy, or other parts of France, in favour of Matilda, or her ſon. We find by the rolls that it was paid in the 1ſt, 2d, 20th, and 21ſt years of Henry II. The low ſtate in which he found the fleet of England might make it neceſſary for that prince to continue this impoſition till the third year of his reign; and the danger of an invaſion from France or Flanders might naturally induce him to revive it in the twentieth. Upon extraordinary occaſions danegelt was levied; and although at the end of that century the name was loſt, a like proviſion was often made, in every age, by our parliaments, for the defence of the Britiſh ſeas, and ſecurity of the kingdom. Lord Lyttelton's Hiſtory, &c. vol. iii. p. 65, &c.

DANE-LAGE. See Common *Law*.

DANE-WORT, in *Botany*. See Sambucus.

Danewort, in *Agriculture*, is a term ſometimes applied provincially to that ſort of elder uſually known by the names of dwarf-elder and wall-wort, (*Sambucus ebulus*). It is remarked

marked by Withering, that the green leaves of this plant drive mice away from granaries; and that the Sileſians ſtrew them where their pigs lie, under the perſuaſion that they prevent ſome of the diſeaſes to which they are liable. It is not eaten either by cows, goats, ſheep, horſes, or ſwine.

DANET, Peter, in *Biography*, a French abbè, known by his dictionary, Latin and French, compoſed for the uſe of the dauphin. He compiled alſo a French dictionary of Greek and Roman Antiquities, in 4to. This was publiſhed in 1698, and has been tranſlated into Engliſh. He was one of the perſons ſelected as editors of the Delphin claſſics: Phædrus fell to his ſhare, but his commentary of this poet gained him little reputation. Moreri.

DANGALA. See Dongola.

DANGCANGHAC, in *Ornithology*, the name given by the people of the Philippine iſlands to the heron. The Spaniards call it *gazza*. It is the ſame ſpecies with that ſo common in Europe. See Heron.

DANGE, in *Geography*, a ſmall town of France, in the department of the Vienne, chief place of a canton in the diſtrict of Chatellerault, with a population of 846 individuals. The canton has an extent of 150 kiliometres, 9 communes, and 6753 inhabitants.

DANGEAU, Louis de Courcillon de, in *Biography*, abbot of Fontaine-Daniel and Clermont, was born at Paris, in 1643. His father was marquis de Dangeau, and his mother was deſcended from Du Pleſſis Mornay, a name celebrated in church-hiſtory as an oracle of Calviniſm. Their ſon was brought up a Proteſtant, but renounced his religion at the perſuaſion of Boſſuet. He travelled when young, and went to Poland, in 1667, as envoy-extraordinary. On his return he devoted himſelf to literature, and entered the church, but with a determination to accept no benefice which required miniſterial duties. He was nominated, in 1671, reader to the king; in this ſituation he uſed his influence in rendering his ſovereign the patron of letters, and was ſo far ſucceſsful that many men of real merit and genius were brought forward by his intereſt. He was admitted a member of the French academy, and became a moſt active and zealous aſſociate. He was particularly attentive to the ſtudy of grammar, and his eſſays on that ſubject were afterwards collected and publiſhed by the abbé Olivet in his Opuſcules ſur la Langue Francoiſe. The abbé Dangeau, himſelf a convert, became zealous in the converſion of others; but his ardour in this work was ſoon abated by the miſconduct of ſome of his diſciples. In the promotion of real knowledge he was very ſedulous, and publiſhed a variety of introductory pieces for the uſe of young perſons. He formed at his own houſe a literary ſociety which aſſembled weekly, and to which were admitted writers diſtinguiſhed for talents in every department of learning. Here all party diſtinctions were forgotten, and the converſation was carried on with perfect liberty. The abbé was celebrated more by his attachment to truth, than by any other circumſtance in life; ſometimes his pertinacity to the line of rectitude was deemed obſtinacy, yet it was admitted on all hands that he was polite, indulgent, well verſed in the manners of the world, humane and liberal to the indigent. He did much good, and was truly benevolent with a very moderate income. He died generally reſpected, and deeply lamented by his friends, in the beginning of the year 1723. Moreri.

Dangeau, in *Geography*, a ſmall town of France, in the department of Eure and Loire; 9 miles N. of Chateau Dun, and 18 S. of Chartres.

DANGER, *Iſlands of*, iſlands in the Southern Pacific Ocean, obſerved by commodore Byron, in June 1765, and ſo called on account of the rocks and ſhoals, which rendered acceſs to them dangerous. They had a more fertile and beautiful appearance than any before ſeen, and like the reſt, ſwarmed with people, whoſe habitations ſtood in cluſters along the coaſt. S. lat. 10° 15'. W. long. 169° 28'.

Danger, *Point*, a cape on the eaſt coaſt of New Holland. S. lat. 28°. E. long. 153° 30'.

DANGERIA, in *Antiquity*, a payment in money made by foreſt tenants, that they might have liberty to plough and ſow in time of pannage.

DANGOLISZKI, in *Geography*, a town of Lithuania; 36 miles S. S. W. of Breſlaw.

DANGU, a ſmall town of France, in the department of the Eure; 3 miles S. W. of Giſors.

DANICHA, a town of Ruſſia, in the government of Tobolſk, on the Chatanga; 360 miles N. N. E. of Turuchanſk. N. lat. 70° 45'. E. long. 98° 14'.

DANIEL, Gabriel, in *Biography*, a French hiſtorian, was born at Rouen in 1649, where he was educated himſelf, and where afterwards he taught others, in the colleges of the Jeſuits. He was invited thence to Paris, to take upon him the office of librarian in the houſe of the order. Of the Jeſuits he was a zealous defender, and wrote in their juſtification in anſwer to Paſchal: the title of his work was "Entretiens de Cleanthe et d'Eudoxe ſur les Lettres Provinciales," for which he was highly applauded by the brethren, but which did not produce the effect deſired. A work of more general intereſt written by father Daniel was, "Le Voyage au Monde de Deſcartes," which was intended as a refutation of the philoſopher's ſyſtem: it has been much read, and tranſlated into Latin, Italian, and Engliſh. But the moſt famous work of this author, and for which he is diſtinguiſhed as an hiſtorian, is the "Hiſtoire de France, depuis l'Eſtabliſhment de la Monarchie Francoiſe." It was publiſhed in 17 vols. 4to. in the year 1756. Voltaire, in ſpeaking of the author, ſays, "He has rectified the faults of Mezerai concerning the firſt and ſecond race. It has been objected to him, that his diction is not always pure, that his ſtyle is too feeble; that he has not given ſufficient information concerning uſages, manners, and laws; that his hiſtory is a long detail of warlike operations, in which a writer of his profeſſion is liable to great miſtakes. His great fault is not to have been informed of the rights of the nation, or to have concealed them: he ſeems to have had no knowledge of the finances, none of the internal condition of the kingdom, or of its manners." Father Daniel, beſides the works enumerated, wrote many others on philoſophical, theological, and critical ſubjects. After a life of intenſe ſtudy and labour, he died at Paris in 1728. Moreri.

Daniel, Peter, the intimate friend of the celebrated George Buchanan, was a native of St. Benoit ſur Loire; but the principal part of his life was ſpent at Orleans. His profeſſion was that of an advocate, and he held the office of *bailli* of the abbey of Fleuri. He was zealouſly attached to critical ſtudies, and attained to an uncommon familiarity with ancient MSS. Scioppius (De Arte Critica) characterizes him as a ſtore-houſe of every ſpecies of antiquities. He lived on terms of intimacy with ſome of the moſt diſtinguiſhed ſcholars of the age. Scaliger and Turnebus acknowledge themſelves indebted to him for the communication of his MSS. treaſures. After his death, which happened in the year 1603, his MS. library was purchaſed by Borgars and Paul Petau, for the ſum of 1500 livres. His only publications were editions of Petronius, Servius, and of the curious relique, entitled "Querolus ſive Aulularia," which is the "Aulularia," of Plautus tranſproſed. To this comedy, which had not formerly been printed, he

prefixed the commendatory verſes of Buchanan. Irving's Memoirs of George Buchanan.

DANIEL, in *Sacred Biography*, one of the Jewiſh prophets, was a deſcendant of the royal family of Judah, as we may partly infer from the book of his prophecies, (chap. i. 3.) and as Joſephus poſitively affirms. Whilſt he was young, as ſome ſuppoſe at the age of 12 years, though others think he might have been older, or not leſs than 18 years of age, he was carried captive from Jeruſalem to Babylon by Aſhpenaz, maſter of the eunuchs, under the order of Nebuchadnezzar, in the 4th year of Jehoiachim, king of Judah, 605 years B. C. Daniel was called Belteſhazzar, and his three companions in exile were Hananiah, Miſhael, and Azariah, who were denominated Shadrach, Meſhac, and Abed-nego. Theſe youths, immediately upon their removal to Babylon, were placed for three years under the tuition of the maſter of the eunuchs, in order to be inſtructed by him in the language and literature of the Chaldeans, previouſly to their admiſſion into the preſence and court of Nebuchadnezzar, as his choſen ſervants. In the 2d year of Nebuchadnezzar's reign at Babylon, from the death of his father, which was the 4th year after his firſt taking of Jeruſalem, B. C. 601, Daniel had liberty of acceſs to the king, and interpreted his dream; upon which he was immediately advanced to be chief of the Magi or wiſe men, and governor of the whole province of Babylon. For this truſt a leſs period than four years could not have been ſufficient for his inſtruction in the language, laws, uſages, and learning of the country; nor, conſidering his youth when he was made captive, could he at an earlier period have been capable of undertaking it. (Dan. ii. 31. 48). Prideaux reckons him at this time about the age of two and twenty. Thus diſtinguiſhed by royal favour, he was not unmindful of his three companions in bondage; but by his recommendation, they were preferred to places of honourable truſt under him in the province of Babylon. Their conſtancy in the profeſſion of their religion is particularly related in the third chapter of his book.

In the 7th year of Zedekiah, the 14th of Nebuchadnezzar, B. C. 591, Daniel had acquired ſuch a character for his wiſdom, and alſo for his piety and virtue, that the prophet Ezekiel (ch. xxviii. 3.) records it as a kind of proverb, "Thou art wiſer than Daniel," in his ironical addreſs to the king of Tyre; and in another place (ch. xiv. 14. 20.) God is repreſented as claſſing him with Noah and Job, and as ſaying, "Though theſe three men, Noah, Daniel, and Job, were in it, they ſhould deliver but their own ſouls by their righteouſneſs." At this time, if we allow him to have been 18, when he was carried away to Babylon, and brought up for the ſervice of the king, he could not have been more than 32 years of age; ſo that he dedicated the prime and vigour of his life to the ſervice of God. In the 36th year of his age, the 11th year of Zedekiah, 587 before Chriſt, he received that honourable teſtimony to his wiſdom already recited. (Ezekiel xxviii. 3.) At this time Nebuchadnezzar returned to Babylon, after the end of the Jewiſh war; and out of the ſpoils collected in that expedition, made a golden image to the honour of Bel his god, which he dedicated to him in the plain of Dura; and on this occaſion he ſummoned all his officers and miniſters to attend, when Daniel's three friends were condemned to the fiery furnace, and were miraculouſly delivered from it unhurt. (Dan. ch. iii.) Daniel himſelf, who was probably preſent, and who, without doubt, did not worſhip the idol, eſcaped accuſation. In the 35th year of Nebuchadnezzar, the 19th year after the deſtruction of Jeruſalem, 570 B. C., he returned from his Egyptian expedition, to Babylon, and there dreamed of a wonderful large tree, and the cutting down of it, of which we have an account in the 4th chapter of the book of Daniel. This dream was interpreted by the prophet, who thus intimated that it prefigured the future circumſtances of the king himſelf. Upon the death of Nebuchadnezzar, in the 43d year of his reign, B. C. 562, he was ſucceeded by his ſon Evilmerodach, or Ilvaradomus, who, after a ſhort reign of two years, fell a ſacrifice to his vices; ſo that his own relations conſpired againſt him, and put him to death. His ſiſter's huſband Nerigliſſar, who was at the head of the conſpiracy, reigned in his ſtead; but this prince being ſlain in the 4th year of his reign, in a battle with Cyrus, his ſon Laboroſoarchod reigned nine months, and was ſucceeded by Nabonadius, the laſt Babyloniſh king, called in Scripture Belſhazzar. In the firſt year of this king's reign, B. C. 555, Daniel had the viſion of the four great beaſts, which repreſented the four monarchies of the Chaldæans, Perſians, Greeks, and Romans, and of the kingdom of the Meſſiah, which was to ſucceed them, which is recorded in the 7th chapter. In the 3d year of Belſhazzar, B. C. 553, he had the viſion of the ram and the he-goat, prefiguring the overthrow of the Perſian empire by Alexander the Great; and he foreſaw alſo the perſecution that was to be raiſed againſt the Jews by Antiochus Epiphanes, king of Syria, the vengeance of God upon him, and the victories of the Maccabees, (ch. viii.) Daniel informs us (ch. v.), that Belſhazzar (in the 17th year of his reign, B. C. 559.) made a great feaſt, on which occaſion he applied to common or profane uſes, the ſacred veſſels, which he had taken out of the temple of Jeruſalem; and in that very night he was ſlain, and Darius the Mede, that is, Cyaxares the uncle of Cyrus, took the kingdom. The hand-writing on the wall, and the awful interpretation of it by Daniel, which he has particularly recorded, are well known. Cyaxares and Cyrus having concerted together for the diviſion of the empire, determined to divide it into 120 provinces, over which were appointed three preſidents, who were to reſide conſtantly at court as the king's miniſters. Of theſe preſidents Daniel was made the firſt; and he was entitled to this preeminence on account of his ſingular wiſdom, approved conduct, and long experience; for he had now, from the 2d year of Nebuchadnezzar, been employed full 65 years as a prime miniſter of ſtate under the kings of Babylon. This ſtation, however, which made him the next perſon to the king in the whole empire, excited the jealouſy and envy of the other courtiers; ſo that they laid that ſnare for him, which occaſioned his being caſt into the lion's den. But being miraculouſly reſcued from injury, this malicious contrivance terminated in the deſtruction of its authors; and Daniel being eſtabliſhed in the favour and confidence of Darius and Cyrus, he greatly proſpered in their time, as long as he lived. (Dan. vi. 28.) In the 1ſt year of Darius, he delivered his famous prophecy of the advent of the Meſſiah, (ſee the next article); and he had alſo another remarkable viſion, in which the angel Gabriel diſcovered to him the events that were to occur in Perſia after the death of Cyrus; *viz.* the arrival of Alexander the Great, the overthrow of the Perſian empire, the Greek dominion, the continued wars between the kingdom of Syria and Egypt, the perſecutions by Antiochus Epiphanes, the deſtruction of that perſecuting prince, and the victory and happineſs of the ſaints. (Dan. x.) Upon the death of Cyaxares, Cambyſes being alſo dead in Perſia, Cyrus returned and aſſumed the whole government of the empire both of the Medes and Perſians, over which he reigned ſeven years. This wiſe and excellent prince had formed a very favourable opinion of Daniel when he firſt came to Babylon and took the city; and when he returned thither again from his Syrian expedition,

tion, the fame of the prophet was augmented, and he had additional reaſons for holding him in high eſtimation. And as Daniel had earneſtly ſupplicated the Almighty for the reſtoration of his people, the Jews, (ſee Dan. ix.) it is reaſonable to imagine that he would intercede for it with the king, and exert his intereſt for the acceleration of this deſirable event. In order to induce him the more readily to comply with his requeſt, he laid before him the prophecies of Iſaiah, (xliv. 28. xlv. 1.), which mentioned him by name 150 years before he was born, as one whom God had deſigned to be a great conqueror, and king over many nations, and the reſtorer of his people, in cauſing the temple to be built, and the land of Judah and the city of Jeruſalem to be again occupied by its former inhabitants. Joſephus tells us, (lib. xi. c. 1.) that Cyrus had ſeen and read theſe prophecies; and it is plain from Scripture that this was the caſe; for they are recited in his decree in Ezra (i. 2.) for the rebuilding of the temple. Who, indeed, was more likely to ſhew theſe prophecies to Cyrus than Daniel, who by his ſtation had conſtant acceſs to him, and who was moſt anxious for ſeeing the accompliſhment of theſe prophecies? When the Samaritans, in the 3d year of Cyrus, B. C. 534, obſtructed and retarded the execution of Cyrus's decree for the rebuilding of the temple; Daniel (ch. x.) ſeems to have ſurrendered himſelf to mourning and faſting for three days; and he afterwards had the viſion already mentioned concerning the ſucceſſion of the kings of Perſia, the empire of the Macedonians, and the conqueſts of the Romans, &c. of which the three laſt chapters of his prophecies contain an account. From what is written in the concluſion of the laſt of theſe, we may infer that he died ſoon after; and, indeed his great age renders it unlikely that he could have ſurvived much longer. For the 3d of Cyrus being the 73d year of his captivity, if he were 18 years old when he was removed to Babylon, he muſt have been in the 91ſt year of his age at this time, a length of years to which few attained in thoſe days. The place of Daniel's death and burial is not aſcertained. Some have ſuppoſed that he died in Chaldæa, being probably detained there by his great employments in the Perſian empire. St. Epiphanius ſays that he died at Babylon, and he is followed by the generality of hiſtorians. Joſephus tells us (Antiq. l. x. c. 12.) that he built a famous edifice of the caſtellated kind at Suſa; and that this was the place where the Perſian and Parthian kings were uſually buried: the copies of Joſephus, now extent, place this building in Ecbatana in Media; but St. Jerom, who gives the ſame account of it *verbatim* out of Joſephus, places it in Suſa in Perſia, whence we may conclude that the copy of Joſephus, uſed by him, had this reading; and this is moſt likely to be true. For Suſa being within the Babyloniſh empire, the Scripture tells us, that Daniel ſometimes reſided there; and it has been a common tradition in thoſe parts for many ages paſt, that Daniel died in that city, which is now called "Tuſter;" and there they ſhew his monument. (Itinerary Benjamin of Tudela.) It is alſo to be obſerved, that Joſephus calls this building Baris, which is the ſame by which Daniel himſelf calls the caſtle or palace at Shuſhan or Suſa. For what we tranſlate "at Shuſhan in the palace," (Dan. viii. 2.) is in the original "Beſhuſhan Habirah," where, without doubt, the Birah of Daniel is the ſame with the Baris of Joſephus; and both ſignifies this palace or caſtle built there by Daniel, while he was governor of that province.

Daniel was a very extraordinary perſon, both for wiſdom and piety, and exhibits an example of conſtancy in maintaining his religious principles and profeſſion, notwithſtanding the temptations of a proſperous and affluent condition, and of a corrupt idolatrous court, which none can contemplate without admiration, and which ought to excite a laudable emulation.

DANIEL, *Book of*, a canonical book of the Old Teſtament, ſo denominated from its author, Daniel, of whoſe hiſtory and character we have given a brief ſketch in the preceding article. See BIBLE and CANON.

The book of Daniel may be divided into two parts; the *firſt* is hiſtorical, and contains a relation of ſeveral incidents that occurred with regard to Daniel himſelf, and the Jews under ſeveral kings at Babylon: the *ſecond*, beginning at the 7th chapter, and ending at the 12th, comprehends the viſions and prophecies, with which he was favoured, and which enabled him to foretell various events, that pertained to the monarchies of the world, the time of the advent and death of the Meſſiah, and the deſtruction of the kingdom of the Jews. Part of this book, *viz.* from the 4th verſe of the ſecond chapter to the end of the 7th chapter, was originally written in the Chaldee language; the reaſon of which was, that in this part the writer treats of the Chaldæan or Babyloniſh affairs, and, therefore, he wrote of them in the Chaldee or Babyloniſh language. The reſt is in Hebrew. The Greek tranſlation of this book, uſed by the Greek churches through all the eaſtern countries, was that which Theodotion had tranſlated. This was adopted by the ancient Chriſtians, becauſe they found the LXX. verſion too faulty to be uſed in their churches. In the vulgar Latin edition of the Bible, as well as in the Greek tranſlation of the book of Daniel by Theodotion, there is added in the third chapter after the 23d verſe, between that and the 24th verſe, the ſong of the three children, Hananiah, Miſhael, and Azariah, who were caſt into the fiery furnace; and at the end of the book, the hiſtory of Suſanna, and of Bel and the Dragon; the former is made the 13th, and the other the 14th chapter of the book in that edition:—but theſe additions were never received into the canon of Holy Writ by the Jewiſh church, neither are they extant either in the Hebrew or the Chaldee languages, nor have we any evidence, that they ever were ſo. That they were originally written in the Greek tongue by ſome Helleniſtic Jew, without having any higher ſource, from which they are derived, appears from this circumſtance, that in the hiſtory of Suſanna, Daniel, in his replies to the elders, alludes to the Greek names of the trees, under which, they ſaid, the adultery charged upon Suſanna was committed, which alluſions cannot hold good in any other language. The church of Rome, however, allows them to be of the ſame authority with the other parts of the book of Daniel; and by their decree at Trent, (ſeſſ. 4.) have given them an equal place with it among the canonical Scriptures. But the ancients never did ſo. Africanus, Euſebius, and Apollinarius have rejected theſe pieces, not only as being uncanonical, but alſo as fabulous; and Jerom gives the hiſtory of Bel and the Dragon no better title than that of "The Fables of Bel and the Dragon." And others, who have admitted them for inſtruction of manners, have, nevertheleſs, rejected them from the canonical Scriptures, in which reſpect they are followed by the Proteſtant churches, which exclude them from the canonical, and aſſign them to the apocryphal writings. See APOCRYPHA and BEL *and the* DRAGON.

The prophecies of Daniel, concerning the advent of the Meſſiah, and other important events, of times far remote from thoſe in which he lived, are ſo clear and explicit, that Porphyry, towards the cloſe of the third century after Chriſt, alleged againſt them, that they muſt have been written

written after the facts to which they refer had occurred. To him they appeared to be a narration of events that had already taken place, rather than a prediction of things to come; ſuch was the ſtriking coincidence between the facts, when accompliſhed, and the prophecies, which foretold them. Porphyry ſeems to have been the firſt perſon who denied their genuineneſs and authority. In the 12th of his 15 books againſt the Chriſtian religion, he attempts to depreciate Daniel's prophecies; alleging, that they were not compoſed by Daniel, whoſe name they bore, but by ſome perſon who lived in Judæa about the time of Antiochus Epiphanes, becauſe all to that time contained true hiſtory, but all beyond that period were manifeſtly falſe. This work of Porphyry (ſee PORPHYRY), together with the anſwers of Euſebius, Apollinarius, and Methodius, is wholly loſt, except ſome few fragments and quotations which are preſerved by Jerom, and others of the fathers. But, as Jerom rightly obſerves, this method of oppoſing the prophecies, affords the ſtrongeſt teſtimony to their truth. For they were fulfilled with ſuch exactneſs, that, to infidels, the prophet ſeemed not to have foretold things future, but to have related things paſt. We may obſerve, in general, that the prophecy relating to the kings of Syria and Egypt, (ch. xi.) which is ſaid to have been written after the times of Antiochus Epiphanes, was tranſlated into Greek 100 years before his time, and the tranſlation was in the hands of the Egyptians, who had no great kindneſs for the Jews and their religion: and thoſe prophecies that foretell the ſucceſſes of Alexander (ch. viii. 5. xi. 3.) were ſhewn to Alexander by the Jews, in conſequence of which they obtained ſeveral privileges from him.

The author of "The Scheme of Literal Prophecy" conſidered, (A. Collins, eſq.) hath followed the ſteps of Porphyry; and formed eleven objections againſt the book of Daniel, concluding with no ſmall degree of confidence, that it muſt have been written in the time of the Maccabees. But his two learned opponents, both of the ſame name, have ſolidly and clearly refuted his eleven objections, and ſhewn that they are all mere cavils, unfounded aſſertions, erroneous quotations, or evident contradictions. (See Biſhop Chandler's Vindication of his Defence of Chriſtianity, and Dr. Samuel Chandler's Vindication of the Antiquity and Authority of Daniel's Prophecies, in Anſwer to the Scheme of Literal Prophecy conſidered.) The following ſummary of Mr. Collins's objections, and the replies to them, may not be unacceptable to the theological reader; and comports with the deſign of the editor in all articles of this kind, which is to defend and eſtabliſh the truth of our holy religion, and the authenticity of the Scriptures, upon which our faith in it depends. Collins objects, *firſt*, that the famous Daniel, mentioned by Ezekiel, could not be the author of the book of Daniel; becauſe Ezekiel, who propheſied in the fifth year of Jehoiakim, king of Judah, ſuppoſes that Daniel at that time was a perſon in advanced life; whereas the book of Daniel intimates that he was then a young man. To this objection it has been replied, that Ezekiel did not propheſy in the fifth year of Jehoiakim, nor in the reign of Jehoiakim at all; but he began to propheſy in the fifth year of the captivity of king Jehoiachin, the ſon and ſucceſſor of Jehoiakim (Ezek. i. 2.) that is, 11 years after. When Daniel was firſt carried into captivity, he might be a youth about 18; but when Ezekiel magnified his wiſdom and piety (ch. xiv. xxviii.) he was between 30 and 40; and ſeveral years before that period he had interpreted Nebuchadnezzar's dream, and was advanced to an honourable ſtation in the court of Babylon (Dan. ii. 48.); and he was therefore very fit and worthy to be celebrated by his fellow-captive Ezekiel. See DANIEL. The *ſecond* objection of Collins is, that Daniel is repreſented in his book as living chiefly at the courts of the kings of Babylon and Perſia; and yet the names of the ſeveral kings of his time are all miſtaken in the book of Daniel. As to the miſtake of the names of the kings, we may obſerve, that there are only four kings mentioned in the book of Daniel, *viz.* Nebuchadnezzar, Belſhazzar, Darius the Mede, and Cyrus. Of the firſt and laſt there never was any doubt; and the other two may be rightly named, though they have been differently denominated by the Greek hiſtorians, who yet differ as much from one another as from Daniel. The Eaſtern monarchs, it is well known, had ſeveral different names: and one writer might uſe one, and another writer might uſe another. Mr. Collins further ſtates, that it is more ſuited to a fabulous writer than to a contemporary hiſtorian, to ſpeak of "Nebuchadnezzar's dwelling with the beaſts of the field, and eating graſs like oxen, &c." and then returning again to the government of his kingdom. It ſhould be conſidered, however, that the caſe of Nebuchadnezzar is related in the prophetic figurative ſtyle: and ſtripped of its figures, the plain meaning is, that Nebuchadnezzar ſhould be puniſhed with madneſs, ſhould fancy himſelf a beaſt and live accordingly, and be obliged to ſubſiſt upon a vegetable diet; but after ſome time ſhould recover his reaſon, and reſume the government. What is there in this account fabulous or abſurd? The dream was not indited by Daniel, but was told by Nebuchadnezzar himſelf. The *third* objection of Mr. Collins is, that the book of Daniel could not be written by that Daniel, who was a captive at Babylon, becauſe it abounds with derivatives from the Greek, which language was unknown to the Jews till long after the captivity: it is not true, that the book of Daniel abounds with derivatives from the Greek; but an affinity is obſervable between ſome few words in the Greek and the Chaldee language; and it is not unreaſonable or unlikely, if we advert to the analogy of languages, that the Greeks derived them from the Chaldee, and not the Chaldees from the Greek; or they might both derive them from a common ſource. Moſt of the words are names of muſical inſtruments; and the Greeks themſelves acknowledge that they received their muſic from the Eaſtern nations, from whence they themſelves originally deſcended. It is objected, *fourthly*, that the book of Daniel does not appear to have been tranſlated into Greek, when the other books of the Old Teſtament were, which are attributed to the LXX.: the preſent Greek verſion, inſerted in the Septuagint, being taken from the tranſlation of Theodotion, made in the ſecond century of the Chriſtian era. It appears, however, that there was an ancient Greek verſion of Daniel, which is attributed to the LXX.; it is cited by Clemens Romanus, Juſtin Martyr, and many of the ancient fathers; it occupied a column of the Hexapla of Origen; and it is quoted ſeveral times by Jerom. This verſion, which had been repudiated by the doctors of the church, and in the room of which Theodotion's was ſubſtituted, was publiſhed ſome years ago from an ancient MS., diſcovered in the Chighian library at Rome. A *fifth* objection is that of Porphyry already ſtated; *viz.* that ſeveral matters of fact are ſpoken of with the clearneſs of hiſtory, to the times of Antiochus Epiphanes; whence Porphyry inferred that the book of Daniel was written about the time of this Antiochus, the author appearing to be well acquainted with things down to the death of this prince, but not farther. This indeed is a ſingular kind of argument againſt the book of Daniel. His prophecies are clear, and therefore are no prophecies. Could

not God who inſpired the prophet, enable him to deliver clear predictions of future events, perfectly known to himſelf? Has he not done ſo in other inſtances? Beſides, there are ſeveral prophecies in Daniel's book, which relate to events far beyond the death of Antiochus; and theſe are as clear as thoſe that pertain to events that occurred before his death. Mr. Collins's *ſixth* objection is, that Daniel is omitted among the prophets, enumerated in Eccleſiaſticus, where it ſeems proper to have mentioned him, if his book had been received as canonical, when Eccleſiaſticus was publiſhed. The author, however, does not profeſs to give a complete catalogue of the Jewiſh canonical writers; others are omitted beſides Daniel. No mention is made of Job and Ezra, and of the books under their name. It is of greater importance, that Daniel is propoſed (1 Maccab. ii. 60.) as a pattern by the father of the Maccabees, and his wiſdom, as we have already ſeen, is highly extolled by Ezekiel; and there are ſufficient teſtimonies of his antiquity, without the confirmation of a later writer. It is further objected, *ſeventhly*, that Jonathan, who made the Chaldee paraphraſes on the prophets, has omitted Daniel; whence it ſhould ſeem that his book was not held in the ſame eſtimation by the Jews with other books of the prophets. The caſe is the ſame with regard to the books of Ezra and Nehemiah; and Jonathan might not have made a Targum or Chaldee paraphraſe on Daniel, becauſe half of the book is written in Chaldee: or if he made ſuch a Targum, it has been loſt as well as others: and, indeed, biſhop Chandler has ſhewn, that there was an ancient Targum on Daniel. After all it deſerves conſideration, that Jonathan frequently applies the prophecies of Daniel, as fuller and clearer than thoſe of other prophets, and we may hence conclude, that he was regarded by him as a prophet of equal authority, at leaſt with thoſe who preceded him. The Jews, indeed, ſince the time of Chriſt, have not regarded Daniel as a prophet, and therefore they have placed his prophecies only among the "Hagiographa;" alleging, that his manner of life was not conformable to that of the other prophets, but he lived like the courtiers and grandees of Babylon; and that, although he had divine revelations communicated to him, it was not in the prophetic mode, but by dreams and viſions of the night, which they reckon to be the moſt imperfect manner of revelation, and below the prophetic. But Joſephus thought very differently. (Antiq. l. x. c. 12.) This Jewiſh writer reckons him among the greateſt of the prophets, and mentions ſome circumſtances relating to his predictions, which evince his ſuperiority to other prophets; and he was always eſteemed a prophet by the ancient Jewiſh church. But the point in diſpute between the Jews and Chriſtians is fully decided by the authority of our bleſſed Lord, who calls him "Daniel the prophet" when he cites his prediction. (Matt. xxiv. 15. Mark xiii. 14.)

"The Jews," ſays the eminently learned biſhop Lowth, (Lectures on the Sacred Poetry of the Hebrews, lib. x. vol. ii. p. 61., &c. Gregory's Tranſlation,) "would refuſe to Daniel even the character of a prophet: but the arguments under which they ſhelter this opinion are very futile: for thoſe points which they maintain concerning the conditions, on which the gift of prophecy is imparted; the different gradations, and the diſcrimination between the true prophecy and mere inſpiration, are all trifling and abſurd, without any foundation in the nature of things, and totally deſtitute of Scripture authority. They add, that Daniel was neither originally educated in the prophetic diſcipline and precepts, nor afterwards lived conformably to the manner of the prophets. I do not, however, comprehend how this can diminiſh his claim to a divine miſſion and inſpiration; it may poſſibly enable us, indeed, to aſſign a reaſon for the diſſimilarity between the ſtyle of Daniel and that of the other prophets, and for its poſſeſſing ſo little of the diction and character of poetry, which the reſt ſeem to have imbibed in common from the ſchools and diſcipline in which they were educated."

It has been objected, *eighthly*, that the part of Daniel's book which is written in Chaldee, reſembles the ſtyle of the old Chaldee paraphraſes; which, being compoſed many hundred years after the time of Daniel, muſt have a different ſtyle from that uſed in his time; and, therefore, that part could not have been written at a period very remote from the date of the eldeſt of theſe Chaldee paraphraſes. This argument is one of thoſe which, by proving too much, proves nothing. According to this mode of reaſoning, Homer cannot be ſo ancient an author as he is generally reputed to be, becauſe the Greek language continued much the ſame many hundred years after his time: but the ſtyle of Daniel's Chaldee differs more from that of the old Chaldee paraphraſes than Homer does from the lateſt of the Greek claſſic writers.

It has been farther objected, *ninthly*, that the book of Daniel ſeems to have been compoſed to do honour to the Jews, in the perſon of Daniel, by making him, as a Jew, ſuperior to all the wiſe men of Babylon. Hence we might infer, that, becauſe books have been counterfeited under the names of perſons of renown, there can be no genuine books of the ſame perſons. Some pieces in Greek have been forged under the name of Daniel, and, therefore, he wrote no book in Chaldee and Hebrew long before thoſe forgeries. Poems have been aſcribed to Homer and to Virgil, which they did not compoſe: and therefore one was not the author of the Iliad, and the other did not write the Æneid. Spurious writings have been attributed to St. Peter and St. Paul, and therefore theſe apoſtles have tranſmitted to us no true writings. As ſome books have been counterfeited in the name of this or that writer; it is a much more probable preſumption than the contrary, that there were ſome genuine books of his writing.

The *tenth* objection is, that the author of the book of Daniel appears plainly to be a writer of things paſt, after a prophetical manner, by his uncommon punctuality, by not only foretelling things to come, like other prophets, but fixing the time when the things were to happen. But other prophets have done the ſame, *e. g.* 120 years for the continuance of the antediluvian world; 400 years for the ſojourning of Abraham's poſterity in a ſtrange land; 40 years for the peregrination of the children of Iſrael; 70 years for the deſolation of Tyre; 70 years for the captivity of Judah, &c.; and, therefore, the fixing of the times and dates cannot be a particular objection againſt the prophecies of Daniel. Joſephus (Antiq. l. x. c. 11.) aſcribes this punctuality to divine revelation, and not, like the objector, to the late compoſition of the book; and deduces from it an argument in proof of the diſtinguiſhing excellence of the prophet.

Laſtly, it is objected, that the book of Daniel gives an imperfect, confuſed, contradictory, obſcure, and emblematical relation of facts, blended with images and ſymbols, unlike the books of the other prophets, and taken from the ſchools of the Greeks. It may be replied, that Daniel's mode of writing was ſuited to his deſign, which was not to compoſe a hiſtory, but to deliver prophecies, and hiſtory merely ſo far as it relates to prophecies. The charge of his contradicting other hiſtorical relations is altogether unfounded. As to the cenſure of his emblems, which are ſaid not to reſemble thoſe of other prophets, and to have been borrowed from the ſchools of the Greeks, this is unjuſt; for ſimilar

emblems

emblems are uſed by other prophets, and they are agreeable to the ſtyle and genius of all the eaſtern writers of his time. So far from having borrowed them from the Grecian ſchools, if any of them ever were uſed by the Greeks, they borrowed them from the oriental writers. The laſt objection ill accords with the *fifth* and *tenth*. *There* obvious matters of fact were narrated with the clearneſs of hiſtory; and the author was charged with forgery, on account of his uncommon punctuality. *Here* all is dark and emblematical, imperfect, and contrary to other hiſtories. Such objections contradict, and deſtroy one another. Both may be falſe, but both cannot be true. Upon the whole, we may obſerve, that the ſtyle of Daniel is not ſo lofty and figurative as that of the other prophets; it is clear and conciſe, and his narrations and deſcriptions are ſimple and natural; and he writes more like an hiſtorian than a prophet.

Of the genuineneſs and authenticity of the book of Daniel, we have all the external and internal evidence, which can be reaſonably deſired. As to external evidence, we have not only the teſtimony of the whole Jewiſh church and nation, which have conſtantly received this book as canonical, but particularly of Joſephus, who commends Daniel as the greateſt of the prophets; of the Jewiſh Targums and Talmuds, which frequently cite and appeal to his authority; of St. Paul and St. John, who have copied many of his prophecies; of our Saviour himſelf, who has cited his words, and ſtyled him "Daniel the prophet;" of ancient hiſtorians, who relate many of the ſame tranſactions; of the mother of the 7 ſons, and of the father of the Maccabees, who both recommend the example of Daniel to their ſons; of old Eleazar in Egypt, who, praying for the Jews then ſuffering under the perſecutions of Ptolemy Philadelphus, (3 Macc. vii. 6, 7.) mentions the deliverance of Daniel out of the den of lions, together with the deliverance of the three men out of the fiery furnace; of the Jewiſh high prieſt, who ſhewed Daniel's prophecies to Alexander the Great, while he was at Jeruſalem; and of Ezekiel, a contemporary writer, who greatly extols his piety and wiſdom. The internal evidence is not leſs convincing; for the language, ſtyle, manner of writing, and all other internal marks and characters, are perfectly agreeable to that age; and he appears plainly and undeniably to have been a prophet, by the exact accompliſhment of his prophecies, as well thoſe which have been already fulfilled, as thoſe which are now fulfilling in the world.

Of the viſions and prophecies of Daniel we ſhall now give a brief account. His firſt prophecy was his interpretation of Nebuchadnezzar's dream, recorded in the ſecond chapter. When the Magi, or wiſe men, had failed to interpret it, and the king had ordered them to be deſtroyed, Daniel offered himſelf to the captain of the guard, benevolently interpoſing for preſerving the lives of the Magi, under a ſentence of deſtruction, and modeſtly aſcribing to divine communication the ſuperior wiſdom which he poſſeſſed. The object of Nebuchadnezzar's dream was a great image, whoſe form was terrible. This image was not an improper emblem of human power and dominion; and the various metals of which it was compoſed do not unaptly typify the various kingdoms which ſhould ariſe. It conſiſted of four different metals, gold, ſilver, braſs, and iron mixed with clay; and theſe four metals, according to Daniel's interpretation, mean ſo many kingdoms; and the order of their ſucceſſion is clearly denoted by the order of the parts; the head and higher parts ſignifying the earlier times, and the lower parts the later times. "The head of the image was of fine gold," (v. 32.) which Daniel interprets as referring to Nebuchadnezzar himſelf, his family, and his repreſentatives. The Babylonian was, therefore, the firſt of theſe kingdoms, fitly repreſented by the head of fine gold, on account of its great riches. But this empire, though of great extent, was yet of no long duration; for it ended in his grandſon Belſhazzar, not 70 years after the delivery of this prophecy, nor above 23 years after the death of Nebuchadnezzar. "The breaſt and arms of the image were of ſilver," (v. 34.) which Daniel interprets in theſe words, (v. 39) "After thee ſhall ariſe another kingdom inferior to thee;" the kingdom which aroſe after the Babylonian, was the Medo-Perſian. The two hands and the two ſhoulders, ſays Joſephus, (Ant. l. x. c. 10. § 4.) ſignify that the empire of the Babylonians ſhould be diſſolved by two kings; who were the kings of the Medes and Perſians, whoſe powers were united under Cyrus, by whom Babylon was beſieged and taken, and who, putting an end to that empire erected on its ruins the Medo-Perſian, or Perſian empire. Thus far all critics and commentators are agreed, that the two firſt kingdoms repreſented in the dream of Nebuchadnezzar were the Babylonian and the Perſian. "The belly and thighs of the image were of braſs," (v. 32.) which Daniel interprets (v. 39.), "And another third kingdom of braſs, which ſhall bear rule over all the earth." Alexander the Great, it is well known, ſubverted the Perſian empire; and therefore the kingdom which ſucceeded to the Perſian was the Macedonian, repreſented by braſs, becauſe, as it is ſaid, the Greeks were famous for their brazen armour. It has been controverted, whether this kingdom terminated in the perſon of Alexander, or was continued in his ſucceſſors. The two thighs of braſs, it is ſuggeſted, might be deſigned to denote the Saleucidæ, who reigned in Syria, and the Lagidæ, who reigned in Egypt, who were the only ſucceſſors of Alexander particularly pointed out, becauſe they had the moſt intimate connexion with the Jewiſh church and nation. The kingdom of Alexander and of his ſucceſſors was one and the ſame kingdom, though Grotius conſidered them as diſtinct; for they are ſo repreſented by all ancient authors. "The legs of the image are of iron, his feet part of iron and part of clay" (v. 33.), which deſcription is interpreted by Daniel (v. 40, 41, 42, 43.) This fourth kingdom is deſcribed as ſtronger than the preceding, and is ſuppoſed to repreſent that of the Romans. The Roman empire was ſtronger and larger than any of the preceding; and the Romans brake in pieces, and ſubdued all the former kingdoms. The two legs of iron might ſignify the two Roman conſuls; and the iron, mixed with miry clay, might intimate that the Romans were defiled by a mixture of barbarous nations. The Roman empire was at length divided into ten leſſer kingdoms, correſponding to the ten toes of the image. Beſides the image, already deſcribed, Nebuchadnezzar ſaw "that a ſtone was cut without hands, which ſmote the image upon his feet that were of iron and clay, and brake them to pieces, &c." (v. 34, 35.) which part of the viſion is interpreted and explained by Daniel (v. 44, 45.) This is underſtood by the ancients of the kingdom of Chriſt, which was ſet up during the days of the kingdom of the Romans. The ſtone was totally a different thing from the image, and the kingdom of Chriſt is totally different from the kingdoms of this world; it was cut without hands, that is, this kingdom was ſpiritual: it was ſet up by the God of heaven, and hence the phraſe of the kingdom of heaven came to ſignify the kingdom of the Meſſiah, as it was underſtood by the Jews, and is applied by our Saviour in the New Teſtament. This kingdom was to "break in pieces and conſume all the kingdoms," to ſpread and enlarge itſelf, ſo that it ſhould comprehend within itſelf all the former

mer kingdoms. This kingdom was to "fill the whole earth," to become univerſal, and to "ſtand for ever."

A revelation, ſimilar to that made unto Nebuchadnezzar, in the ſecond year of his reign, concerning the four great empires of the world, was communicated to Daniel with ſome different circumſtances, in the firſt year of Belſhazzar, or about 48 years afterwards. (Dan. vii.) To Daniel the repreſentation was, not in the form of a great image, but in the ſhape of great wild beaſts. The firſt kingdom is repreſented by a beaſt (v. 4.) that "was like a lion, and had eagle's wings, &c.;" this is the kingdom of the Babylonians, which, by the figures of a lion, the king of beaſts, and an eagle, the king of birds, is deſcribed as the firſt and nobleſt kingdom. The eagle's wings denote ſwiftneſs and rapidity; and the conqueſts of Babylon were very rapid; that kingdom having been advanced to its height within a few years by a ſingle perſon, under the conduct and arms of Nebuchadnezzar. The ſecond kingdom is repreſented (v. 5.) by "another beaſt like a bear, &c." This is the kingdom of the Medes and Perſians, and, on account of their cruelty and thirſt for blood, they are compared to a bear. Its three ribs are underſtood by Jerom, Vatablus, and Grotius, to denote the three kingdoms of the Babylonians, Medes, and Perſians; but ſir Iſaac Newton and biſhop Chandler explain them, as ſignifying the kingdoms of Babylon, Lydia, and Egypt, which were conquered by it, but were not properly parts and members of its body. They might be called ribs, as the conqueſt of them much ſtrengthened the Perſian empire; and they might be ſaid to be between the teeth of the bear, as they were much grinded and oppreſſed by the Perſians. The third kingdom is repreſented (v. 6.) by "a beaſt like a leopard, &c." which aptly repreſents the kingdom of the Macedonians; the ſwiftneſs of the leopard denoting the rapidity of Alexander's conqueſts; its ſpots being emblematic, according to Bochart, of the different manners of the nations which Alexander commanded, or, according to Grotius, of the various diſpoſitions and manners of Alexander himſelf, who was alternately merciful and cruel, temperate and drunken, abſtemious and incontinent. The principal point of likeneſs ſeems to conſiſt in the ſwiftneſs and impetuoſity of the one and the other. The fourth kingdom is repreſented (v. 7.) by a "fourth beaſt, dreadful and terrible, &c." which can pourtray no other than the Roman empire. The 10 horns of this beaſt repreſent 10 kingdoms, which are variouſly enumerated by different writers. Machiavel (Hiſt. Flor. lib. i.) gives them under the following names; *viz.* the Oſtrogoths in Mœſia, the Viſigoths in Pannonia, the Suevi and Alani in Gaſcoigne and Spain, the Vandals in Africa, the Franks in France, the Burgundians in Burgundy, the Heruli and Thuringii in Italy, the Saxons and Angles in Britain, the Huns in Hungary, and the Lombards at firſt upon the Danube, and afterwards in Italy. Mr. Mede (Works, B. iii.), reckons up the 10 kingdoms in the year 456, the year after Rome was ſacked by Genſeric, king of the Vandals, in the following manner: *viz.* Britons, Saxons in Britain, Franks, Burgundians in France, Wiſigoths in the ſouth of France and part of Spain, the Suevi and Alani in Gallicia and Portugal, the Vandals in Africa, the Alemanni in Germany, the Oſtrogoths, ſucceeded by the Longobards, in Pannonia, and afterwards in Italy, and the Greeks in the reſidue of the empire. Biſhop Lloyd (Addenda to Lowth's Comm. p. 524.) exhibits the following liſt, adding to each the time of its riſe; *viz.* Huns about A. D. 356, Oſtrogoths 377, Wiſigoths 378, Franks 407, Vandals 407, Suevi and Alani 407, Burgundians 407, Heruli and Thuringii 476, Saxons 476, and Longobards, who began to reign in Hungary, A.D. 526, and were ſeated in the northern parts of Germany, about the year 483. Sir Iſaac Newton (Obſ. on Daniel, chap. 6.), enumerates them thus: the kingdom of the Vandals and Alans in Spain and Africa, that of the Suevians in Spain, that of the Wiſigoths, that of the Alans in Gallia, that of the Burgundians, that of the Franks, that of the Britons, that of the Huns, that of the Lombards, and that of Ravenna. The number of theſe kingdoms was not conſtantly 10, but ſometimes more and ſometimes fewer; but, as ſir Iſaac Newton obſerves, whatever was their number afterwards, they are ſtill called the "ten kings," from their firſt number.

Beſides theſe 10 horns or kingdoms, another little horn was to ſpring up among them (v. 8.) which Grotius, Collins, and ſome others have ſuppoſed to be Antiochus Epiphanes, without ſufficient reaſon; but we are more probably to ſeek for it in the weſtern Roman empire; and it is commonly conceived to denote the pope of Rome, whoſe power, as a horn or temporal prince, was eſtabliſhed in the eighth century. All the kingdoms above deſcribed will be ſucceeded by the kingdom of the Meſſiah. (v. 9, 10.)

Daniel had another viſion in the third year of the reign of Belſhazzar, or about 553 years B. C. (ch. viii. 1.) This viſion was that of a ram and he-goat. Here we have two beaſts denoting two empires. The Babylonian is omitted, becauſe its fate was nearly terminated. The ram with two horns was the empire of the Medes and Perſians, or the Medo-Perſian empire, founded by Cyrus. Mr. John Mede (Works, B. iii.), conjectures, that the Hebrew word for a ram, and that for Perſia, *i.e.* אַיִל and אֵלָם, both ſpringing from the ſame root, and both implying ſomewhat of ſtrength, the one is not improperly made the type of the other. Beſides, it was uſual with the king of Perſia to wear a ram's head, made of gold, and adorned with precious ſtones, inſtead of a diadem; for thus Ammianus Marcellinus deſcribes him. Biſhop Chandler, Wetſtein, and others, obſerve, that rams' heads with horns, one higher and the other lower, are ſtill to be ſeen on the pillars at Perſepolis. The exploits of the ram are recapitulated in verſe 4; and it is well known that, under Cyrus, the Perſians extended their conqueſts weſtward, as far as the Ægean ſea, and the boundaries of Aſia; northward, they ſubdued the Armenians, Cappadocians, and various other nations; ſouthward, they conquered Egypt. Under Darius they ſubdued India.

The next animal that commands our notice in this viſion is the he-goat (v. 5.); which is properly the type or emblem of the Grecian or Macedonian empire, becauſe the Macedonians at firſt, about 200 years before Daniel, were denominated "Ægeadæ," or the goat's people; the city Ægeæ or Ægæ, was the uſual burying place of the Macedonian kings. In verſes 6 and 7 we have an account of the overthrow of the Perſian empire by the Grecians; for, as the Perſians, in the reigns of Darius Hyſtaſpis and Xerxes, had poured down with great armies into Greece, the Grecians, in their turn, carried their arms into Aſia, and the he-goat invaded the ram that had invaded him. The empire of the goat, as deſcribed in the prophetic language, was in its full ſtrength, in conſequence of the rapid and extenſive conqueſts of Alexander, when he died at Babylon; but, in the ſpace of about 15 years, the royal family became extinct, and the governors of provinces aſſumed the titles of kings. By the defeat and death of Antigonus in the battle of Iſſus, theſe were reduced to four; *viz.* Caſſander, Lyſimachus, Ptolemy, and Seleucus, who parted between them the dominions of Alexander, and ſettled them into four kingdoms. Theſe are the four notable horns, which came up in the room

of the firſt great horn; and they are the ſame as the four heads of the leopard in the former viſion. The prophecy ſays, that they were to extend "towards the four winds of heaven;" accordingly, in the partition of the empire, Caſſander held Macedon and Greece, and the *weſtern* parts; Lyſimachus had Thrace, Bithynia, and the *northern* regions; Ptolemy poſſeſſed Egypt, and the *ſouthern* countries; and Seleucus obtained Syria and the *eaſtern* provinces. Thus were they divided towards the four winds of heaven. Here a little horn is deſcribed as riſing among the four horns of the Grecian empire, (v. 9, 10, 11, 12.) This is explained in the verſes 23, 24, 25. The little horn is generally underſtood, both by Jewiſh and Chriſtian, and ancient and modern interpreters, to mean Antiochus Epiphanes, king of Syria, who was a great enemy and cruel perſecutor of the Jews. Sir Iſaac Newton entertains a different opinion; nor, indeed, according to the interpetation of other parts of this propheey already given, is it likely that the little horn ſhould ſignify Antiochus Epiphanes, or any ſingle king; but it ſhould denote ſome kingdom, *i. e.* ſome government, ſtate, or polity in the world, either monarchical, republican, or ſome other form. Our views are, therefore, directed to the Romans. When they gained footing in Greece, they then became a horn of the goat. Out of this horn they proceeeded, and were at firſt a little horn, but in proceſs of time they overtopped the other horns; extending their arms from Greece, and overrunning the other parts of the goat's dominions, perſecuting and oppreſſing the people of God, wherever they came. This horn, as ſir Iſaac Newton juſtly obſerves, was to riſe up in the N.W. parts of thoſe nations, which compoſed the body of the goat, and from thence was to extend their dominion towards Egypt, Syria, and Judæa. Another remarkable property of the little horn, and that diſtinguiſhed it from all others, was, that "his power ſhould be mighty, but not by his own power," which deſcription applied more juſtly to the Romans than to Antiochus Epiphanes, or any other ſovereign or kingdom. The ſtrength of the other kingdoms conſiſted in themſelves, and had its foundation in ſome part of the goat; but the Roman empire, as a horn or kingdom of the goat, was not mighty by its own power, or by virtue of the goat, but drew its nouriſhment and ſtrength from Rome and Italy. There grew that trunk and body of the tree, though the branches extended over Greece, Aſia, Syria, and Egypt. The remainder of the prophecy relates chiefly to the perſecution and oppreſſion of the people of God. (v. 24.) Antiochus was perſecuting and oppreſſive to the Jews, but his power was limited, and laſted only for a ſeaſon; but the Romans poſſeſſed and exerciſed a more extenſive and durable power to oppreſs and injure. "He took away the daily ſacrifice" for a few years; but the Romans for many ages; and they utterly deſtroyed the temple, which he only ſpoiled and profaned. When he took Jeruſalem, he ſlew 40,000, and ſold as many more; but when the city was beſieged and taken by the Romans, the number of captives amounted to 97,000, and of the ſlain to 11 hundred thouſand. The Romans put an end to the government of the Jews, and entirely took away their place and nation. It is added, "he ſhall alſo ſtand up againſt the prince of princes." If by the "prince of princes" we underſtand the high-prieſt, it is true that Antiochus appointed and removed the high-prieſts at pleaſure; but the Romans took away the whole adminiſtration. If by the "prince of princes" we underſtand the Meſſiah, Antiochus had no ſhare in the completion of the prophecy; it was effected by the Romans. By the malice of the Jews, but by the authority of the Romans, our Saviour was put to death; and he ſuffered the puniſhment of the Roman malefactors and ſlaves. Moreover, the perſecuting power of Rome, whether Pagan or Chriſtian, whether exerciſed towards the Jews or towards the Chriſtians, by the emperors or by the popes, is ſtill the "little horn." The tyranny is the ſame; but as exerted in Greece and the Eaſt, it is the little horn of the he-goat, or the third empire; as exerted in Italy and the Weſt, it is the little horn of the 4th beaſt, or the 4th empire. But the little horn, like other tyrannical powers, was to come to a remarkable end; "he ſhall be broken without hand;" *i. e.* it ſhall fall, not by the hand of man, but by a ſtroke, as it were, from heaven, ſhall it periſh; in other words, the dominion of the Romans ſhall finally be deſtroyed with ſome extraordinary manifeſtation of the divine power. Antiochus Epiphanes died, indeed, in a very extraordinary manner. (See ANTIOCHUS *Epiphanes*.) But, though in a variety of particulars, the prediction of Daniel may be applicable to his exploits, and to his character, and the general hiſtory of his life, and though it has been thus generally applied; yet it ſeems to have a more extenſive reference, and to receive itsfull accompliſhment in the conduct and hiſtory of the Romans. The anxiety and concern felt by Daniel in the view of the events, that were likely to befal his country and countrymen, ſeem to intimate his apprehenſion of ſome more grievous and permanent calamities which would befal them, than any Antiochus Epiphanes would have it in his power to inflict. In this inſtance, and indeed in every other, Daniel exhibits a moſt amiable temper, no leſs ſolicitous for the honour of religion than for the welfare of his country; alike pious and public ſpirited; and no leſs eminently a patriot than a prophet.

The memorable events which were revealed to Daniel, in the viſion of the ram or he-goat, are again more clearly and explicitly revealed to him in his laſt viſion; ſo that this latter prophecy may not improperly be ſaid to be a comment and explanation of the former. This revelation was made (ſee ch. x. 1.) in the third year of Cyrus king of Perſia, when Daniel was very far advanced in years; and the prophecy delivered in conſequence of it muſt comprehend the fate and fortune of the people of God for many years. It muſt extend much further than from the 3d year of Cyrus, B.C. 535, to the death of Antiochus Epiphanes, B. C. 165, which was not above 370 years. It comprehends in reality many ſignal events after that time to the end of the world. The firſt prophecy relates to the Perſian empire, which was then ſubſiſting. "Behold, there ſhall ſtand up three kings in Perſia, &c." (xi. 2.) *i. e.* after Cyrus the founder of the empire, who was then reigning. Theſe three kings were Cambyſes, the ſon of Cyrus, Smerdis the Magian, who pretended to be another ſon of Cyrus, and was really an impoſtor; and Darius, the ſon of Hyſtaſpes, who married the daughter of Cyrus; "and the fourth ſhall be richer than they all." The fourth, after Cyrus, was Xerxes, the ſon or ſucceſſor of Darius. Of him it is ſaid that "by his ſtrength through his riches he ſhall ſtir up all againſt the realm of Grecia." Accordingly Xerxes's expedition into Greece is one of the moſt memorable adventures in ancient hiſtory. Xerxes, in raiſing his army, ſearched every place of the continent; and his army is ſaid to have amounted, including ſoldiers and followers of the camp, to 5 millions, 283 thouſand, 220 men. He alſo ſtirred up the weſt, and engaged his allies the Carthaginians to collect an army of 300 thouſand men, and a fleet of 200 ſhips. Alexander is characterized in verſe 3, as "a mighty king that ſhall rule with great dominion, and do according to his will." This prediction is amply verified in the extenſive conqueſts and arbitrary mandates of Alexander. (See his article.) But his kingdom was ſoon to be broken and divided (v. 4.) We have already ſhewn how ſoon his glory terminated,

terminated, and how his kingdom was divided. In this prophecy two out of the four kingdoms into which his empire was divided, are ſpecified, *viz.* Egypt and Syria, which were by far the moſt conſiderable, and continued diſtinct kingdoms, after the others were ſwallowed up by the Romans. The kings of Egypt and Syria are denominated, in reſpect to the ſituation of theſe countries to Judæa, the kings of the *ſouth* and the *north*. "The king of the ſouth," it is ſaid, "ſhall be ſtrong;" which was verified when Ptolemy had annexed Cyprus, Phœnicia, Caria, and many iſlands, and cities, and regions, to Egypt; and, moreover, by the acquiſition of Cyrene, he was become ſo great, as to be the terror of all his enemies. Nevertheleſs, Seleucus Nicator, the king of the north, was "ſtrong above him;" for, having annexed the kingdoms of Macedon and Thrace to the crown of Syria, he was become maſter of three parts out of four of Alexander's dominions. "In the end of years," ſays the prophet, "they ſhall join themſelves together," &c. (v. 6.) All theſe particulars, and thoſe mentioned in verſes 7—30, were verified by the events, which we cannot now recite. This prophecy concerning the kingdoms of Egypt and Syria, from the death of Alexander to the time of Antiochus Epiphanes, is ſo particular and circumſtantial, that it is really more perfect than any hiſtory. The prophecy is equally exact beyond the time of Antiochus, extending to remoter ages, and reaching even to the general reſurrection. The ſequel of the prophecy is ſuppoſed by Porphyry, among the ancients, and by Grotius, among the moderns, to have been literally accompliſhed in Antiochus Epiphanes. Others, however, as Jerom, and moſt of the Chriſtian fathers, conſider Antiochus as a type of Antichriſt. Others again underſtand what remains partly of the tyranny of Antiochus, and partly of the great apoſtaſy of the latter days, or the days of the Roman empire. Others again apply it wholly to the invaſion and tyranny of the Romans, the ſubſequent corruptions in the church, and alterations in the empire. But our limits will not allow us to detail the particulars. For an application of the celebrated prophecy relating to the Meſſiah (ch. ix. 24. 27.), and an account of the exactneſs with which it was accompliſhed, we ſhall refer to the article PROPHECY. See alſo WEEK.

We ſhall now conclude this extended article, with the reflections of biſhop Newton on Daniel's prophecy of the things noted in the Scriptures of truth, recorded in chap. xi. "Upon the whole, what an amazing prophecy is this, comprehending ſo many various events, and extending through ſo many ſucceſſive ages, from the firſt eſtabliſhment of the Perſian empire, above 530 years B. C., to the general reſurrection! And the further it extends, and the more it comprehends, the more amazing ſurely, and the more divine it muſt appear, if not to an infidel like Porphyry, yet to all who, like Grotius, have any belief of revelation. How much nobler and more exalted the ſenſe, more important and more worthy to be known by men, and to be revealed by God, when taken in this extended view, and applied to this long and yet regular ſeries of affairs, by the moſt eaſy and natural conſtruction; than when confined and limited to the times and actions of Antiochus, to which yet it cannot be reconciled by the moſt ſtrained and unnatural interpretation! What ſtronger and more convincing proofs can be given or required of a divine providence, and a divine revelation; that there is a God who directs and orders the tranſactions of the world, and that Daniel was a prophet inſpired by him, "a man greatly beloved," as he is often addreſſed by the angel! Our bleſſed Saviour hath beſtowed upon him (Matt. xxiv. 15.) the appellation of "Daniel the Prophet;" and this is authority ſufficient for any Chriſtian; but in this work have been produced ſuch inſtances and atteſtations of his being a prophet, as an infidel cannot deny, or, if he denies, cannot diſprove. The character that is given of him by Joſephus, is nothing more than ſtrictly his due. It expreſſeth the ſenſe of the Jewiſh church: and the ſame muſt be the ſentiments of every man, who will conſider and compare the prophecies and events together. This hiſtorian is commending the ſuperior excellence of Daniel's predictions; "for he was wont, ſays he, not only to foretell future things, as other prophets alſo did; but he likewiſe determined the time wherein they ſhould happen." Afterwards, having mentioned ſome of Daniel's prophecies, he proceeds thus: "All theſe things, God having ſhewn them to him, he left in writing, that they who read them, and behold the events, might admire Daniel for the honour vouchſafed him by God; and by theſe things might be convinced how much the Epicureans are miſtaken, who deny a providence, and allow not that God regards human actions, nor that all things are governed by a bleſſed and immortal Being for the preſervation of the whole, but aſſert that the world is carried on at random, without a guide or ruler: which, if it was without a governor, as they pretend, would have been deſtroyed by the blind impulſe, and have periſhed and come to nought, as we ſee ſhips, which are deſtitute of pilots, overwhelmed by the ſtorms, and chariots overturned and broken to pieces, which have no drivers. For, by theſe things predicted by Daniel, they appear to me widely to err from the truth, who declare, that God hath no care of human affairs; for we ſhould not ſee all things ſucceed according to his prophecies, if it happened that the world was governed by chance." Prideaux's Connection. Dupin's Hiſt. of the Canon. Newton's Diſſertations on the Prophecies. Calmet's Dict.

DANIEL, in *Geography*, a ſmall iſland in the river Meuſe, a little below Stockem, in the biſhopric of Liege.

DANIEL, *Eau de*, a ſpring of mineral water, in the department of the Gard, in France, not far from Alais, the chief place of the department.

DANIEL, *Port*, lies on the northern ſide of Chaleur bay, and is a commodious harbour for veſſels of a conſiderable draught of water. It affords a cod-fiſhery, and is about nine leagues from Pato, W.N.W. of Cape Deſpair.

DANILOF, a diſtrict and town of Ruſſia, in the government of Yaroſlaf, ſeated on a rivulet that falls into the Volga; 28 miles E.S.E. of Yaroſlaf, and 360 E.S.E. of Peterſburg.

DANILOWICZE, a town of Lithuania, in the palatinate of Wilna; 44 miles S. of Braſlaw.

DANK, in *Agriculture*, a term made uſe of to ſignify damps, humid, moiſt, or wet, as applied to graſs, &c.

DANK, in *Commerce*, a piece of ſilver current in Perſia, and in ſome parts of Arabia, weighing the ſixteenth part of a drachm. It is alſo a weight uſed by the Arabians to weigh jewels and drugs.

DANKALI, in *Geography*. See DANCALI.

DANN, a ſmall town of France, in the department of the Meurthe, diſtrict of Sarrebourg, three miles N. of Phalſbourg, remarkable for a mineral ſpring, called La Bonne Fontaine, which is conſidered as a ſure remedy againſt hemorrhagies.

DANNA, in *Ancient Geography*, a town of Paleſtine, ſituated in the mountains of the tribe of Judah.

DANNEBERG, or DANNENBERG, in *Geography*, a ſmall town of Germany, on the river Jetze, not far from the Elbe, 48 miles S.E. of Luneburg, and 90 N. by E. of Brunſwick, in the duchy of Luneburg Zell, belonging to the king of England, as elector of Hanover, but at preſent in the poſſeſſion of the French. It has about 1000 inha-

bitants, and its diſtrict, which is nearly 40 Engliſh miles in circumference, comprehends 77 villages. Near Dannenberg is a decayed caſtle, at the entrance of which is a tower, where Waldemar II. king of Denmark, is ſuppoſed to have been confined, in the year 1223, by Guntzel, count of Schwerin: but Buſching very juſtly thinks it more probable that Tannberg, in the duchy of Mecklenburg Schwerin, was the place of the Daniſh king's confinement.

DANNEMARIE, a ſmall town of France, in the department of the Upper Rhine, chief place of a canton in the diſtrict of Befort, with a population of 724 individuals. The canton has 27 communes, and 7630 inhabitants, upon a territorial extent of 110 kiliometres.

DANNEMORA, a famous Swediſh iron mine, near Oſterby, 26 Engliſh miles N.W. of Upſal, in the government of Upſal, which yields the beſt iron in the world. It has no ſubterraneous galleries. The pits are deep excavations, like gravel pits, into which the miners go down and from which they are drawn up in a bucket. The richeſt ore yields 70, the pooreſt 30 *per cent.* The collective maſs gives upon the average one third of pure metal. Twelve thouſand tons are annually drawn from the mine, and yield four thouſand tons of bar-iron. The maſs of ore occupies a comparatively ſmall compaſs. Conſidered as one, the length of the pits is 760 feet, and the breadth from three to twelve. The ore runs in veins from eaſt to weſt. The richeſt pit is near 500 feet deep, and the great pit (Storymningen) has not yet been fathomed. The matrix of the ore, being a calcareous earth, contains but little ſulphur, which is perhaps the reaſon of the ſuperior quality of the iron. Cox's Travels.

Near 300 perſons are employed in mining and tranſporting the ore. The water is drawn out of the pits in ſummer by pumps worked by water, and in winter by a ſteam engine, which is not uſed in ſummer, on account of the ſcarcity and dearneſs of coals, and is often heated with wood.

In ſummer the ore which is dug is laid out in heaps, and during the winter months it is conveyed on ſledges to the forges; the four principal of which are Leufsta, Oſterby, Gimo, and Akerby.

The mine of Dannemora conſiſts of twelve pits belonging to thirteen different proprietors. Baron de Geer poſſeſſes more than one-third of the whole mine.

Notwithſtanding the mine of Dannemora has been wrought theſe 320 years, having been diſcovered in the year 1448, it yet yields a vaſt quantity of iron of a ſuperior quality, much uſed in the Engliſh ſteel manufactures of Sheffield and Birmingham.

The ſale of the Dannemora iron in England is a monopoly in the hands of two Engliſh commercial houſes, one at London, the other at Hull. They procure it excluſively for the Britiſh manufactures, by a ſpecial contract with the proprietors of the mine.

DANNGE, a river of Pruſſia, which runs into the ſea at Memel.

DANNOCKS, in *Agriculture*, a term provincially applied to hedging gloves or mittens.

DANT, or LANT, in *Zoology*, called by the Africans *Lampt*, an animal of the figure of a ſmall ox, but having ſhort legs. It has black horns, which bend round and are ſmooth. Its hair is whitiſh, and its hoofs are black and cloven. It is ſo ſwift that no animal, except the Barbary horſe, can overtake it. Theſe dants are common in the deſerts of Numidia and Libya, and ſeveral northern provinces of Africa. Buffon ſuppoſes that this animal is the ſame with the dwarf ox, or *Zebu*, which ſee. The name dant has been transferred from Africa to America, and applied to a very different animal. See TAPIR.

DANTE, ALIGHERI, in *Biography*, a celebrated Italian poet, was born at Florence in 1265. He was initiated at an early age to the ſtudy of the ſciences, and of polite literature under Brunetto Latini. He attached himſelf to the profeſſors of the ornamental arts who flouriſhed at that period; but was his own maſter in the art of poetry in which he afterwards ſo much excelled. When he had attained to years of manhood he joined the military defenders of his country, and was engaged in two actions, one againſt the Aretines, in 1289, the other againſt the Piſans, in 1290. In the following year he married Gemma, the daughter of Manetto de Donati, from whom, after having had ſeveral children, he ſeparated. He entered public life, and was conſiderably employed in the affairs of the Florentine republic. In 1300 he was one of the chief magiſtrates of Florence, an honour which proved the ſource of many of his misfortunes. At that period all the towns of Italy were diſtracted by the oppoſite parties of the Guelphs and Ghibellines; and in Florence a further diſtinction took place in the factions of the Neri and Bianchi, or Blacks and Whites. Dante belonged to the latter, of which a more full account will be given under the word FLORENCE: ſuffice it to ſay, his party was overpowered, and himſelf impriſoned, with the loſs of his property. He was afterwards baniſhed, and ſentence of death paſſed upon him, ſhould he again fall into the power of the Florentine ſtate. The poet, after this, may be traced to Padua, Urbino, Bologna, and various other places. When Henry of Luxembourg was elected emperor, Dante ſedulouſly paid his court to him, in hopes that by his means he might be reſtored to his country: but the death of Henry in 1313 cut off all the hopes of Dante.

About this period he went to Paris, where he engaged in the ſtudies of the univerſity. He here made a literary diſplay of his talents by holding a ſolemn diſputation on ſome theological queſtions, in which, according to the manners of the age, he was well verſed. From this time he ſeems to have roved about Italy in an indigent and diſtreſſed condition, till he was hoſpitably received by the lord of Ravenna, a patron and proficient in letters. By him Dante was employed in ſome political negociations, and was ſent to Venice, in order to compromiſe a quarrel which had ariſen between him and the republic. The Venetians, however, refuſed to admit Dante to an audience, by which he was ſo much affected, that ſoon after his return to Ravenna, he died on the 14th of Sept. 1321. Funeral honours and a ſplendid monument were given him by his patron, who alſo pronounced an oration over the dead body. A new and more ſumptuous monument was erected to his memory in 1780, by the legate cardinal Gonzaga, bearing the following inſcription: "Danti Aligherio, poetæ ſui temporis primo, Reſtitutori politioris humanitatis."

The Florentines now began to be aſhamed of their enmity to this great man: they made many efforts to obtain his remains, in order to pay them that reſpect and honour which they merited; and Michael Angelo offered to execute, gratuitouſly, a monument which ſhould be worthy of the poet. But Ravenna would not grant them the honour. The fame of Dante did not, however, depend on marble or braſs: his "Divina Commedia" has given him an unfading and immortal reputation. The ſubject of this work is the deſcription of a viſion in which the author is led through hell, purgatory, and paradiſe; it is full of extravagances, but it contains a variety of paſſages of ſingular ſtrength and ſublimity. The admirers of this poem

contend that no work of Italian poetry bears ſuch a ſtamp of original and ſublime genius; and that in grandeur of conception, warmth of feeling, and energy of expreſſion, no compoſition of modern times can compare with it. Scarcely had this poem appeared, before it became the object of univerſal admiration throughout Italy: copies of it were multiplied, and commentaries written for its illuſtration. Its firſt expoſitors were the ſons of the poet; and in 1373 a profeſſorſhip was eſtabliſhed at Florence, for the expreſs purpoſe of explaining Dante to the public: the firſt perſon who filled the chair was Boccacio. The beſt edition is that of Venice, in three vols. quarto, publiſhed in 1757. Boccacio has deſcribed Dante as of a middle ſtature; of a penſive and melancholy expreſſion in his countenance. His gait was compoſed, his manners grave and ſedate, his addreſs courteous and civil, his way of living extremely temperate. He is ſaid to have been a very abſent man, of which inſtances have been recorded; once meeting with a book in an apothecary's ſhop, which he had been long looking for, he opened it, and read from morning to night without being rouſed from his purſuit by the diſtraction and tumult occaſioned by a great wedding paſſing through the adjacent ſtreet. Dante was a conſiderable writer in the Latin as well as in his own language: but his "Commedia" is the only work to which he is indebted for celebrity. Gen. Biog. Moreri.

Danté, Ignatius, an Italian mathematician of the 16th century, a native of Perugia, was deſcended from a family eminent for their knowledge of the ſciences. His father was a mathematician and an architect, and he himſelf applied ſo aſſiduouſly to the ſtudy of mathematics, that he was invited to Florence by the grand duke Coſmo: here he was treated with the utmoſt liberality; and here he left, as monuments of his fame, a marble quadrant, an equinoctial and meridian line on the front of the church of St. Maria Novella. He removed to Bologna after the death of Coſmo, where he was appointed mathematical profeſſor, and here, in the church of Saint Petronius, he traced the meridian, which was completed by Caſſini. He was afterwards employed by pope Gregory XIII. in reforming the calendar, and in the conſtruction of the maps of Italy in the Vatican gallery. For this labour he was preſented with the biſhopric of Alatri, which he did not enjoy any length of time. He died Oct. 19, 1586, at the age of 49, leaving behind him ſome mathematical treatiſes. Gen. Biogr. Moreri.

Dante, Jean Baptise, native of Perugia, a mathematician, who flouriſhed towards the end of the fifteenth century. He is ſaid to have invented a method of making artifical wings, ſo well proportioned to the weight of the body that he was able to fly: he made many ſucceſsful experiments, but at length one of his wings failed him, when he was exhibiting at a grand ſpectacle; he fell upon the church of Notre Dame, and was ſeriouſly wounded. He, however, recovered under the hands of an able ſurgeon, and afterwards taught the mathematics at Venice. He died at the age of forty. Moreri.

DANTELLE', in *Heraldry*, the ſame with danché, or rather with dancetté, *viz.* a large open indenture. See Dancette.

DANTHELETÆ, in *Ancient Geography*, a people who, according to Ptolemy, inhabited Thrace. This author aſſigns them the town of Pantalia.

DANTZIC, or Dantzick, in the Poliſh language *Gdantzk*, in German *Danzig* or *Dantzig*, in Latin *Gedanum* or *Dantiſcum*, in *Geography*, an ancient and large city of Poliſh or Weſtern Pruſſia, in that part which, from having anciently belonged to the duchy of Pomerania, has retained the name of Little Pomerania or Pomerellia, is ſeated on the leaſt of the ſeveral branches of the river Viſtula, which form the iſlands called the *Dantziger Werder*. Hence large veſſels have not depth of water ſufficient to come loaded into the harbour, although Dantzic is but four miles from the place where the Viſtula falls into the Baltic ſea. The harbour at the town admits only ſhips of one hundred tons burthen; thoſe of greater burthen deliver and receive their cargoes at Weixel or Weichſel Munde, *Viſtulæ Oſtium*, the mouth of the Viſtula; and when the weather is calm, in Dantzic road, called the *Fahrwaſſer*, which is from eight to fifteen fathoms deep.

The city of Dantzic is bounded on the Eaſt by the Viſtula, on the ſouth by the kingdom of Pruſſia, on the north by the Baltic ſea, and on the weſt by the duchy of Pomerania, which belongs to the king of Pruſſia. It is ſituated in E. long. 18° 36', and N. lat. 54° 22' 23" twenty-four miles N. W. of Marienburg, and thirty-two N. W. of Elbing, 76 miles N. of Thorn, 150 N. W. of Warſaw, 260 N. of Cracow, 220 N.E. of Breſlau, 80 miles S.W. of Konigſberg, 260 S.W. of Riga, 900 N.E. of Paris, and 540 S.W. of St. Peterſburg. Two ſmall rivers, the Radaun and Motlau, run through the city, which is divided into three towns, the Vorſtadt (Fore town), Altſtadt (Old town), and Reichsſtadt (Imperial town,) with their reſpective ſuburbs, St. Albrecht or Albert, Old Scotland, Stoltzenberg, Hagelberg, Biſchofsberg, Schidlitz, Langefuhr, and New Scotland. Stoltzenberg which is ſituated on a high ſandy hill, to the weſt by ſouth, commands a fine view of the town and harbour, with the ſhips' road, even to the ſea. But moſt of the ſuburbs were burnt down in 1806, when Dantzic was beſieged by the French.

The circumſtance of two of the ſuburbs of Dantzic being called Old and New Scotland, is owing to the ſignal ſervices which a gentleman, of the Scotch family of the Douglas, rendered to the city whilſt it was beſieged by the Poles, in conſequence of which the Scots obtained privileges that induced numbers of them to ſettle at Dantzic in the ſeventeeth century.

The corn magazines or granaries form a ſeparate town of lofty buildings, divided into ſeveral ſtreets. It has no communication with the city but by a large drawbridge, being completely encompaſſed by water, ſo that boats may load and unload at each granary's door. Few of theſe magazines are lower than five ſtories, and each ſtory is provided with funnels or pipes to let down the corn from one chamber into the other. Not a ſingle individual is allowed to lodge in this corn iſland, which is guarded at night by fierce maſtiffs let looſe by their keepers, who quit the iſle ſoon after ſun-ſet, when the bridge is drawn up.

The houſes at Dantzic are of brick and ſtone, commonly five, ſix, or more ſtories high, with a ſort of gallery called a *Beyſchlag* on the outſide of the ground floor projecting into the ſtreet, in the middle of which gallery there is an aſcent of a few ſteps to the principal entrance of the houſe. Several ſtreets have rows of trees on each ſide. The principal buildings are the cathedral, the guildhall, the arſenal built in 1606, the public weigh-houſe, and the exchange; but they are old ſtructures generally more remarkable for their antiquity than for their elegance.

Dantzic was the firſt town of Poland that embraced the Lutheran perſuaſion in the year 1525. It counts fourteen Lutheran churches, two belonging to Calviniſts, one to Roman Catholics, and before its ſurrender to the French, in 1807, it had alſo an Engliſh chapel. There are ſeveral hoſpitals and charitable foundations.

Cluverius, or Cluvier, the celebrated geographer, is the moſt illuſtrious learned man that was born at Dantzic, although

though it boaſts of a gymnaſium or academy which has ſeveral profeſſors; of an extenſive public library, and of a ſociety for promoting the ſtudy of natural hiſtory.

In 1709, Dantzic was ſeverely viſited by the plague, which ſwept off above 40,000 of its inhabitants; yet their number, in 1730, is ſaid to have approached 200,000. But this computation is evidently erroneous, for in the year 1752, when the trade of Dantzic was ſo flouriſhing that 1014 ſhips entered inwards, Buſching ſtates the number of deaths to have been only 1846, which, calculating even at one in fifty, gives but 92,300 inhabitants. In the year 1774 Ludwig von Baczko, a very reſpectable Pruſſian author, eſtimates the population of Dantzic at 50,000. In 1802, nine years after it had been forced to ſubmit to the king of Pruſſia, Dantzic contained 47,000 inhabitants, beſides the garriſon; and in 1804, including the garriſon, its whole population amounted to 60,097.

Dantzic was formerly at the head of the Hanſeatic league in the north. Towards the end of the fourteenth century its trade was conſiderable, having already engroſſed all the foreign commerce of Culm and Thorn. Before the diſaſtrous war of 1806, its own ſhipping was numerous, and more than 1000 ſhips were reckoned to enter inwards annually: but in that unfortunate year the number of veſſels arrived was only 379, and of thoſe that ſailed 408. In the year 1803 there entered into the ſeveral ports of Great Britain only, 204 ſhips from Dantzic.

The principal ſtaple commodity is corn of all ſorts bought up in Poland, of which Dantzic ſhips annually from 40 to 50,000 laſts. It alſo exports oak planks, timber, ſtaves, wax, honey of a ſuperior kind, hemp and flax, yarn, potaſs, cordials, a large quantity of ſpruce beer, known in England by the name of black beer, and a variety of other articles. Its principal manufactures, beſides the diſtilleries and breweries, are thoſe of ſaltpetre, potaſs, woollen cloth, hardware, and refined ſugar.

According to Buſching, it appears from ancient records that, ſo early as the year 997, Dantzic was a conſiderable commercial town; it is, however, generally ſuppoſed that, till the year 1164, it conſiſted only of ſome fiſhermen's cottages; that Maſleirn the ſecond duke of Pomerania, dying without male iſſue, left it to Primiſlaus, king of Poland, who annexed it to the crown, and in 1295 erected it into a city. In 1310, the knights of the Teutonic order rendered themſelves maſters of Dantzic, and by them it was firſt walled round in 1343. In the year 1454 Caſimir IV., king of Poland, reconquered Dantzic, and granted great privileges to the citizens, who afterwards, in defence of the Lutheran confeſſion, ſided with Maximilian of Auſtria againſt the Poles, which provoked king Stephen Battori to beſiege Dantzic in 1577; but, by the mediation of other princes, the citizens were reſtored to all their former immunities and liberties in 1597. In the year 1632 Dantzic was made a member of the ſtate in the Poliſh diets, and admitted to a vote on the election of a king of Poland. For a long ſeries of years Dantzic continued a free republic, with a territory of above 40 miles in circumferance, under the protection of Poland. In 1655 Dantzic ſtrenuouſly adhered to the intereſt of John Caſimir V., king of Poland, whom Charles Guſtavus of Sweden had unjuſtly attacked, and by ſhutting its gates to the invader, put a barrier to the victories of the Swedes, ſaved the kingdom of Poland, and occaſioned five years after an honourable concluſion of the war, by the peace of Oliva in 1660.

The weakneſs of Dantzic, as a ſtate, expoſed it to frequent moleſtations from the neighbouring powers, who often exacted from it large contributions; and though in 1706 the queen of England, the king of Pruſſia, and the ſtates of Holland, entered into a league to protect it, yet the czar, Peter I. of Ruſſia, called twice on Dantzic for large ſums.

In 1734 Staniſlaus, king of Poland, took refuge in this city, which ſubmitted to Auguſtus III., only after Staniſlaus had made his eſcape. From that time till the year 1752, Dantzic was frequently convulſed by ſerious diſſenſions between the magiſtrates and the citizens, which terminated by the *Ordinatio regia civitati Gedanenſi præſcripta.*

At the firſt partition of Poland, in 1772, the king of Pruſſia, by obtaining Weſt Pruſſia, extended his dominions to the very gates of Dantzic, and even occupied ſome of its ſuburbs. This circumſtance, and the eſtabliſhment of a cuſtom-houſe at Fordon, where the king of Pruſſia levied heavy tolls upon the articles that were brought from Poland to Dantzic, depreſſed the commerce of this city to ſuch an intolerable degree, that the expiring republic claimed the protection of Ruſſia againſt the oppreſſions of Pruſſia. Several diplomatical notes were exchanged in the years 1784 and 1785, but Dantzic obtained very little redreſs; and at the ſecond partition of Poland in 1793, it acknowledged the Pruſſian ſway. Under the protecting influence of the then powerful kingdom of Pruſſia, the trade of Dantzic revived, and had nearly regained its ancient importance, when the diſaſtrous war of 1806, between France and Pruſſia, plunged this flouriſhing town into a ſtate of great diſtreſs. At the approach of the enemy the ſuburbs were burnt down, and, during a ſiege of ſeveral months, about 3000 buildings in the town itſelf were conſiderably damaged. The whole damage has been eſtimated at ten millions of dollars, or nearly one million and a half ſterling. At length the Pruſſian general count Kalkreuth ſurrendered Dantzic, by capitulation, to the French marſhal Lefebvre, who on this occaſion received the title of duke of Dantzic from the French emperor.

On the 10th of July, 1807, Dantzic recovered its old conſtitution as a free republic under the protection of Ruſſia, Saxony and Pruſſia, and the territory which it had poſſeſſed before the year 1772, being nearly fifteen miles in extent round the city, beſides the Dantzic Werder, and the Dantzic or Friſche Nehrung. The former is an uncommon fertile iſland formed by a branch of the Viſtula and the river Motlau, containing twelve pariſhes and thirty-three villages. The latter is a narrow ſlip of land between the Friſche Haf and the Baltic ſea, 50 Engliſh miles long and not more than two miles and a half broad in its greateſt breadth, containing five pariſhes.

Agreeably to its former conſtitution Dantzic was divided into three cities, each of which had its particular burgomaſter or major. Theſe three burgomaſters, a limited number of aldermen, and a common council of one hundred citizens, elected promiſcuouſly out of the three cities, formed together one ſenate, to which all matters relating to the government of the republic were referred. How far this conſtitution is at preſent acted upon, it is difficult to know; Dantzic having ſtill a French garriſon, which it is to retain till a general peace, or at leaſt what is termed a maritime peace between Great Britain and France, takes place. In the mean time trade is at a ſtand, and there is every reaſon to ſuppoſe that the inhabitants of Dantzic are ſubject to the martial law of the French, or nearly ſo. The French general Rapp is governor of the place. His proclamations take precedency of the decrees of the Dantzic ſenate, which till this moment has not diſtinguiſhed itſelf by

by any tranſaction that characterizes a perfectly independent ſtate.

DANTZIGERS, or PRUSSIANS, in *Eccleſiaſtical Hiſtory*, a ſect of the refined anabaptiſts (ſee FLEMINGIANS), ſo called on account of their adopting the manners and diſcipline of the Pruſſians.

DANUBA, in *Geography*, a town of Africa, in the kingdom of Tomani.

DANUBE, *The*, in German the *Donau*, is the moſt conſiderable river of Germany, its courſe, without reckoning its windings, being computed at 1620 miles. It has its ſource near the ſmall town of Doneſchingen, in the court-yard of the palace of the princes of Furſtenberg; and although the two ſmall rivers of Bribach and Brege, which unite below the town, are far more conſiderable than the ſtreamlet that flows into them from Doneſchingen ſoon after their junction, yet this little ſtream alone has the honour of being acknowledged as the ſource of the mighty Danube. Two celebrated Swiſs writers, Sceuchzer and Fæſi, have contended that the Danube riſes in Swiſſerland, becauſe the river Inn, which actually has its ſource in the canton of the Griſons, is 890 feet wide at the place where it joins the Danube, whilſt the width of the latter is only 784 feet. But the rivulet which comes from Doneſchingen has the name of the Danube, or Donau, long before it reaches the river Inn; and admitting that the Danube is narrower and cramped up by hills where it meets the Inn, it is yet certain that it contains much more water upon equal ground, and is already a much mightier river than the Inn far above Ratiſbon, even before it has received four ſmaller rivers. Suabia, therefore, is the true birth-place of the majeſtic Danube, with which only the Volga, amongſt the European rivers, can vie.

The Danube is one of the few rivers that flow from eaſt to weſt. From its ſource it runs N.E. to Ulm, where, in the month of October, 1805, it overflowed its banks, with a violence which had been unparalleled ſince the time of Louis XIV., particularly in the night that preceded the diſgraceful capitulation of general Mack.

From Ulm the Danube continues its north-eaſt courſe to Ratiſbon, from whence it runs ſouth-eaſtwards to Deckendorf, where it receives the river Iſer. It was here that Dr. Burney entered the Danube, on his aquatic excurſion from Munich to Vienna. This ſouth-eaſt courſe goes on to Vilohofen, where there is a wooden bridge of ſixteen arches. In this part the Danube abounds in rocks, ſome above water, and ſome below, which occaſion a great noiſe, owing to the rapidity of the current running over or againſt them. The ſame courſe holds to Paſſau; at the end of which town there is a confluence of three rivers, the Inn on the right hand, the Iltz on the left, and the Danube in the middle. After this junction, the Danube becomes more and more rapid; the ſhore on each ſide, for a conſiderable way below Paſſau, has high hills and rocks, covered with ſpruce fir-trees, and box.

As far as Ingelhartzeil, or the entrance into Auſtria, the Danube is compreſſed and ſhut up between two high mountains; and ſometimes the noiſe againſt rocks is as loud and as violent as a cataract. The river continues running through a woody, wild, and romantic country. For fifty miles not a corn-field or paſture is to be ſeen. At Aſha the country opens a little. Here river after river comes tumbling into the Danube, and yet it grows rather more deep than wide by theſe acceſſions; many ſmall rivers detach themſelves again from it; and iſlands are frequently formed in the middle of this world of waters.

Towards Lintz the Danube runs almoſt full eaſt, through a flat country, with high mountains covered with trees at a diſtance. At Lintz there is a bridge over the Danube of twenty very wide arches.

At Spieburg there is a water-fall. Ens is here in ſight upon the right hand. The courſe of the Danube now becomes extremely irregular, and inclines a while to the ſouth, and then to N.E. The river is ſometimes like a ſea, ſo wide, that there is ſcarce any land in ſight; at other times it is broken and divided into ſmall ſtreams by iſlands.

At Strudel, which is ſituated in a very wild country, is the famous water-fall and whirl-pool, which, in winter, often proves fatal to boats that are drawn into its vortex. At Ips the country opens, and is very beautiful. Beyond Melk the country grows more and more wild as far as Stein. The rocks are often ſo high on each ſide of the Danube, as to prevent the ſun from being ſeen. At Stein, which is on the left of the river, there is a wooden bridge of twenty-five wide arches, which leads to Krems on the right-hand of the Danube.

As the Danube rolls on to the S.E. towards Vienna, the country becomes leſs ſavage. The vine grows on the hills, and innumerable iſlands divide the Danube.

From Vienna the Danube flows to the S.E. towards Preſburg, and below the town of Haimburg quits Auſtria and Germany to enter Hungary. From Preſburg to Comorn it continues to the eaſt, but afterwards flows to the ſouth, and even a little to the ſouth-weſt, and then again ſouth-eaſt, towards Belgrade and Widdin, when it runs on eaſtwards, dividing Bulgaria from Wallachia, and diſcharges itſelf at laſt by ſeveral channels into the Black ſea, in the province of Beſſarabia. It is ſo deep between Buda and Belgrade, that men of war have been navigated upon it, and yet it is not navigable to the Black ſea, on account of the cataracts.

The Danube abounds in fiſh; particularly the *huſo*, Iſin. in Latin *antacæus*, in the Ruſſian language *beluga*, of which is made the glue known in commerce by the name of *iſinglaſs* in Latin *ichthyocolla*; but this fiſh is much more plentiful in the Volga.

The Danube is ſuppoſed to have been the northern boundary of the Roman empire in Europe; towards its mouth the ancients called it the *Iſter*; which ſee.

The courſe of the Danube, with regard to its length, compared with the Thames, is as 7 to 1, or ſix times longer than the Thames.

DANUBE, in *Mythology*, a river worſhipped by the Scythians, on account of the great extent of its water. This river deity is exhibited on a medal of Trajan, ſitting with his urn, and diſtinguiſhed by a large veil floating over his head: but the fineſt figure of him is to be ſeen on the column of Trajan at Rome. Mr. Spence (Polymetis) ſays, that he is one of the firſt figures on that column, very near the baſe; and that he appears there, from the waiſt upward, riſing out of his ſtream, to ſhew his duty to the Romans, and to ſupport the bridge of boats, which they had laid over it. The hand of the god may be diſcerned, though partly covered with the water, ſtretched quite to the bridge, and ſome way under it, as willing to ſupport it.

DANUM, in *Ancient Geography*, a town of Albion, marked in Antonine's Itinerary between Segelocum or Agelocum, and Legeolium. It is the preſent Doncaſter.

DANVERS, in *Geography*, a townſhip of America, in the ſtate of Maſſachuſetts and county of Eſſex, adjoining Salem on the N.W. in which it was formerly comprehended by the name of Salem village. It conſiſts of two pariſhes, and contains 2643 inhabitants; and it was incorporated in 1757.

1757. The moſt conſiderable and compact ſettlement in it is formed by a continuation of the principal ſtreet of Salem, which extends more than two miles towards the country, having many work-ſhops of mechanics, and ſeveral for retailing goods. Large quantities of bricks and coarſe earthen ware are manufactured here. Another pleaſant and thriving ſettlement lies at the head of Beverly river, called New-Mills, where a few veſſels are built. The town of Danvers receives an annual compenſation of 10*l.* from the proprietors of Eſſex bridge, on account of the obſtruction of the river. A ſlitting tide-mill was erected here in 1797. On the ſame dam are a griſt-mill, an anchor ſhop, a ſcythe-ſhop, whoſe hammers are carried by water, and a ſhovel-manufactory.

DANVILLE, a thriving poſt-town of America, in Mercer county, and formerly the metropolis of Kentucky, pleaſantly ſituated, in a large fertile plain, on the S.W. ſide of Dick's river; 35 miles S.S.W. of Lexington. It conſiſts of about 50 houſes, and a Preſbyterian church, and contains 270 inhabitants, of whom 101 are ſlaves. N. lat. 37° 30′. W. long. 85° 30′.—Alſo, a very thriving town-ſhip in the ſtate of Vermont, and county of Caledonia; it was a few years ago a wilderneſs, and now contains 1544 inhabitants; 8 miles N.W. of Barnet.—Alſo, a thriving poſt-town in Pittſylvania county, and ſtate of Virginia, ſituated on Dan river, on the main road from Philadelphia to the Moravian town, N. Carolina.—Alſo, a poſt-town of Northumberland county, in Pennſylvania, on the Suſquehanna, at the mouth of Mohoning creek; 12 miles above Northumberland.

DANYCLOW, a town of Poland, in the palatinate of Lemberg; 64 miles E. of Lemberg.

DANZI, Mademoiselle, afterwards *Madame* le Brun, in *Biography*, with many excellencies, an extenſive compaſs of voice, a good figure, and a great knowledge of muſic, was cold and unintereſting in her performance. She was an admirable inſtrumental performer on the piano-forte, in Emanuel Bach's ſtyle, and had more expreſſion with her fingers than voice.

DAOLA, in *Mythology*, a Tonquineſe idol, who preſides over travellers.

DAON, in *Geography*, a town of France, in the department of the Mayenne, and diſtrict of Chateau-Gontier; 2 leagues S. of Chateau-Gontier.

DAONA, in *Ancient Geography*, a town and alſo a river of India, on the other ſide of the Ganges. Ptolemy.

DAONUS, or Daos, in *Mythology*, a deity of the ancient Chaldæans.

DAOULAS, or Doulas, in *Geography*, a ſmall town of France, in the department of Finiſterre, and chief place of a canton, in the diſtrict of Breſt. It has but 440 inhabitants. The canton, which has an extent of 235 kiliometres and 10 communes, contains a population of 13,799 individuals.

DAOURIAN Mountains, mountains of Aſiatic Ruſſia. See Nershinsk.

DAOURITA. See Schorl.

DAPALIS, in *Mythology*, an epithet of Jupiter, deduced from the great feſtivals celebrated in honour of him.

DAPHNÆ, Pelusiæ, in *Ancient Geography*, a town of Egypt, 16 miles from Peluſium, on the route from Memphis, near the canal of Peluſium formed by the Nile.

DAPHNÆUS, in *Mythology*, an epithet of Apollo, deduced from the fable of his amours with Daphne.

DAPHNE, Δαφνη, in *Antiquity*, a kind of divination, taken from the crackling of laurel leaves thrown into the fire.

Daphne, in *Botany*, (after the nymph Daphne, in alluſion to her transformation into a laurel; ſome of this genus having the aſpect of laurels. Linnæus, it ſeems, originally deſigned this name for his *andromeda polifolia*; but having found ſo apt a denomination for that plant, he applied *daphne*, as it remains at preſent, to the *thymelæa* of Tournefort, the latter name being, according to his rules, untenable, as compounded of another eſtabliſhed one, *thymus*.) Linn. Gen. 192. Schreb. 260. Willd. Sp. Pl. v. 2. 415. Juſſ. 77. Claſs and order, *octandria monogynia*. Nat. Ord. *Thymelææ*, Juſſ.

Gen. Ch. *Cal.* of one leaf, funnel-ſhaped; externally rude; internally coloured; its tube cylindrical; border four-cleft, ſpreading, ſhorter than the tube, deſtitute of glands or crown at the baſe. *Cor.* none. *Stam.* Filaments eight, inſerted in two rows into the tube, and encloſed within it, very ſhort; anthers roundiſh, erect. *Piſt.* Germen, ovate, ſuperior; ſtyle very ſhort; ſtigma capitate, depreſſed. *Peric.* Drupa roundiſh, coloured, juicy, of one cell. *Seed* ſolitary. Some ſpecies are dicœcious.

Eſſ. Ch. Cal. coloured, funnel-ſhaped, four-cleft, withering, including the ſtamens. Cor. none. Drupa of one ſeed.

About 30 or more ſpecies of this elegant genus are known, ſome of which have a lateral, others a terminal, inflorescence. Their habit is ſhrubby, tough and flexible, often ſilky; their inner bark invariably compoſed of fine ſattin-like white, and ſhining fibres. Leaves ſimple, moſtly ever-green, without ſtipules. Flowers more or leſs cluſtered, externally rude, ſilky, and frequently greeniſh; internally ſmooth, red, white, or yellowiſh; for the moſt part highly and agreeably ſcented. Fruit red or black. Every part of theſe plants is highly acrid; and hence they have, in conſideration moreover of their habit, obtained the names of ſpurge-laurel, and ſpurge-olive. D. *mezereum*, common mezereon, Engl. Bot. t. 1381, found apparently wild in ſome parts of England, belongs to the firſt ſection (flowers lateral), and is frequent in gardens. The leaves are ſmooth, deciduous, and come after the flowers, which are crimſon, occaſionally white, and appear in the early ſpring. Their fragrance is ſo ſtrong as to be, to ſome perſons, intolerable in a room. The bark of the root eſpecially, is uſed in medicine as a powerful ſtimulant. This ſpecies is propagated by ſeeds, or by ſuckers from the root. D. *alpina*. (D. altaica, Pallas, Roſſ. t. 35.), is another hardy ſpecies, a native of the Alps, eaſily raiſed from ſeeds in our gardens, eſpecially in bog-earth. Its flowers are white and ſweet-ſcented. Leaves deciduous, ſmoothiſh. D. *laureola*, ſpurge-laurel, Eng. Bot. t. 119, is frequent in ſhady woods and thickets. Its flowers are green, and ill-ſcented. Berries black. The tuft of ſhining leaves, crowning the naked ſtem, gives this ſhrub an elegant palm-like aſpect. D. *pontica*, Andr. Repoſ. t. 73, firſt found by Tournefort in the Levant, and figured in his voyage, has of late become frequent in our gardens, where it is very hardy, and very acceptable. The leaves are ever-green. Flowers copious, early, greeniſh-yellow, exhaling in the evening a rich, pungent, lemon-like odour.—Of thoſe with terminal flowers, D. *odora*, Sm. Exot. Bot. t. 47, is remarkable for its ſweet white bloſſoms. In order to have them in perfection, the heat of a ſtove, in the autumn and winter, is requiſite; otherwiſe the plant itſelf is almoſt hardy enough to bear our climate; but it ſcarcely ever flowers in the open ground. D. *collina*, Sm. Spicil. t. 18. Curt. Mag. t. 428. Neapolitan mezereon, is very able to bear our hardeſt winters, though an ever-green, and a native of Italy, Greece, &c. Its ſweet roſe-coloured flowers, produced in ſpring, or even in the winter, if mild, and its dark-ſhining leaves,

leaves, ſilky beneath, render this a very deſirable plant. It is increaſed by budding on D. *laureola*, or by ſeeds. D. *cneorum*, Curt. Mag. t. 313, an elegant and fragrant Alpine ſhrub, is rather more difficult to keep in a garden. It requires bog-earth, and regular moderate ſupplies of water. D. *lagetto* produces a kind of lace from the artificial extenſion of its inner bark. It it a native of Jamaica.

Daphne, in *Gardening*, comprehends plants of the low, ſhrubby, ornamental, ever-green, and deciduous kinds; of which the ſpecies moſtly cultivated are the mezereon (D. *mezereum*); the wood, or ſpurge laurel (D. *laureola*); the ſilver-leaved daphne, or tartouraira (D. *tartouraira*); the trailing (*daphne cneorum*); and the ſweet-ſmelling daphne, (D. *odora*).

Method of Culture.—Theſe plants are capable of being raiſed in different methods, according to the kind and nature of them.

The firſt ſort and varieties are beſt propagated by ſowing the ſeeds or berries, as ſoon as they have become perfectly ripe, as about Auguſt, on beds of light ſandy earth, covering them in to the depth of half an inch. When poſſible, a ſouth-eaſterly aſpect ſhould be choſen. And, to preſerve the ſeeds in a perfect ſtate, the ſhrubs ſhould be netted in the latter end of the ſummer, to prevent the attacks of the birds, by which they are very liable to be injured.

The young plants generally appear in the following ſpring, when they ſhould be kept clear from weeds, and the largeſt ones removed when too cloſe together: they may remain in theſe beds till the beginning of the ſecond autumn, when they ſhould be removed, and ſet out in nurſery-rows, at the diſtance of a foot and a half, and ten or twelve inches in the rows, great care being taken not to break or injure their roots. After they have had two years' growth in theſe ſituations, they are in a proper condition for being planted out where they are to remain: and as the plants flower very early in the ſpring, the beſt time for removing them is in the early part of the autumnal ſeaſon.

The plants grow to the greateſt ſize, and flower in the moſt full and perfect manner, when the ſoils are of a dry quality: as in moiſt adheſive ſoils they are apt to become moſſy, and grow in a very imperfect manner.

The ſecond ſpecies may be increaſed by ſowing the ſeeds in the ſame manner as the above; and alſo by cuttings and layers of the young ſhoots; theſe ſhould be planted out or laid down in the beginning of the autumn, and in the following autumn they will be well rooted: the layers may be taken off and planted where they are to remain, or put into nurſery-rows as above. The cuttings may, likewiſe, be treated in the ſame way.

And the third and fourth ſorts ſucceed beſt when raiſed from ſeed procured from abroad, and ſown on a warm dry ſituation, in the early autumn, in the places where the plants are to remain, as they do not bear tranſplanting well. The ground ſhould be as little as poſſible ſtirred about the plants. The former ſhould have a dry warm aſpect, where the land is poor, but the latter ſucceeds in ſuch as are more cool: theſe plants are ſufficiently hardy to ſucceed in the open air, when the winters are not very ſevere.

The laſt ſort is raiſed by ſowing the ſeeds, procured from its native ſituation, on a gentle hot-bed, in the autumn or ſpring, and when the plants are of ſufficient growth, removing them into ſeparate pots, to be placed under the protection of the green-houſe. It is much more tender than the other ſorts, not being capable of bearing the open air in cold weather.

The firſt and ſecond kinds are highly ornamental plants in the clumps, borders, and other conſpicuous parts near the houſe; the former flowering early; and, where many are together, affording a fine fragrance.

The other ſorts, though more tender, are curious, and afford an agreeable variety, in aſſemblage with others of ſimilar growth, either in the borders, or among potted plants.

Daphne *Mezereum*, in *Pharmacy*. Many parts of the mezereon are diſtinguiſhed for their extreme acrimony, eſpecially the berries and bark both of the trunk and root. It is the root which is employed in medicine.

When a piece of the root is chewed, at firſt it appears equally without taſte as ſmell; but after a time, a ſenſe of heat and pungency in the fauces comes on, which increaſes to a painful degree, and is remarkably permanent, often remaining for many hours, and not to be waſhed away or removed. This pungency is ſo intenſe in the berry or freſh bark, as to corrode the cuticle of the tongue and fauces, and when it has ſubſided, an inſenſibility of theſe organs remains for ſome time.

Two ounces of the bark digeſted with hot water affords, (according to Murray,) about two drams of a gummy extract, and with ſpirit, 48 grains of reſin. Both theſe preparations poſſeſs the acrimony of the entire plant.

The mezereon root was firſt introduced into this country as an ingredient in the compound decoction of ſarſaparilla or Liſbon diet drink, and was afterwards employed alone in the cure of venereal nodes by Dr. Ruſſel. The formula which he gives, and which has been adopted by the Edinburgh college, is two drams of the mezereon, and half an ounce of liquorice-root boiled with three pints of water down to a quart. From four to eight ounces of this decoction may be given four times a day. This medicine produces ſcarcely any ſenſible effect except a moderate heat in the mouth as already mentioned, and ſometimes it excites perſpiration.

The mezereon has alſo been uſed with advantage in rheumatic complaints, and in ſeveral obſtinate cutaneous affections.

The bark of the mezereon is in popular uſe in France, as a ſtimulant application to the ſkin, to excite a ſerous diſcharge, which it effects, without actually bliſtering; a practice which deſerves a further trial, and might often ſuperſede with advanntage ſome of the ſtimulating plaſters and unguents now in uſe. A piece of the bark, cut of the required ſize, is ſteeped for a ſhort time in vinegar, and then bound upon the ſkin. It ſhould be renewed every day. It is apt, however, to produce eruptions on the contiguous ſkin.

Daphne, in *Geography*, a river of Paleſtine which runs into the Leſſer Jordan, at ſome diſtance from lake Samochonites.

Daphne, a very conſiderable village of Aſia, in Syria, ſituated on the river Orontes, near its mouth in the Mediterranean, reckoned a ſuburb of Antioch, though at the diſtance of 4 or 5 miles from it. Here Seleucus planted a thick grove of laurels and cypreſſes, reaching 10 miles in circumference, and forming in the moſt ſultry ſummer a cool and impenetrable ſhade. In the middle of the grove he erected a magnificent temple which was conſecrated to Apollo and Diana, and he made the whole an aſylum. Daphne was the ſame with reſpect to Antioch that Baiæ was to Rome, and Canopus to Alexandria, a place of reſort for amuſement and pleaſure. Here a thouſand ſtreams of the pureſt water, iſſuing from every hill, preſerved the verdure of the earth, and the temperature of the air; the ſenſes were gratified with harmonic ſounds, and aromatic odours; and

and the tranquil grove was devoted to Bacchus and Venus, to health and joy, to luxury and love. With regard to voluptuous gratification and enjoyment, it was ſo infamous that "Daphnicîs moribus vivere," *i. e.* to live after the manners of Daphne, became a proverb, expreſſing the moſt luxurious and diſſolute mode of living; and all that had any reſpect for modeſty and virtue avoided the place. The ſoldier and the philoſopher wiſely ſhunned the temptations of this ſenſual paradiſe, where pleaſure aſſuming the character of religion, imperceptibly diſſolved the firmneſs of manly virtue. Caſſius, the Roman general, when he came to Antioch, prohibited his ſoldiers, by public proclamation, and under penalty of being caſhiered, from viſiting Daphne, that they might not be corrupted by its luxury and debaucheries. Nevertheleſs the groves of Daphne continued for many ages to attract the veneration of natives and ſtrangers; the privileges of the holy ground were enlarged by the munificence of ſucceeding emperors; and every generation added new ornaments to the ſplendour of the temple. When Julian, on the day of the annual feſtival, haſtened to adore the Apollo of Daphne, his devotion was raiſed to the higheſt pitch of eagerneſs and impatience. His lively imagination anticipated the grateful pomp of victims, of libation, and of incenſe; a long proceſſion of youths and virgins, clothed in white robes, the ſymbols of their innocence; and the tumultuous concourſe of an innumerable people. In his time there was an oracle at Daphne, which was deſtroyed by the Chriſtian emperors: and Julian complained, that inſtead of hecatombs of fat oxen, ſacrificed by the tribes of a wealthy city to their tutelar deity, he found only a ſingle gooſe, provided at the expence of a prieſt, the pale and ſolitary inhabitant of this decayed temple. The altar was deſerted, the oracle had been ſilenced, and the holy ground was profaned by the introduction of Chriſtian and funereal rites.

After Babylas, a biſhop of Antioch, who died in priſon in the perſecution of Decius, had reſted near a century in his grave, his body, by the order of Cæſar Gallus, was tranſported into the midſt of the grove of Daphne. A magnificent church was erected over his remains; a portion of the ſacred lands was uſurped for the maintenance of the clergy, and for the burial of the Chriſtians of Antioch; and the prieſts of Apollo retired, with their affrighted and indignant votaries. As ſoon as another revolution ſeemed to reſtore the fortune of Paganiſm, the church of St. Babylas was demoliſhed, and new buildings were added to the mouldering edifice, which had been raiſed by the piety of Syrian kings. Julian was anxious to deliver the oppreſſed deity from the odious preſence of the dead and living Chriſtians; the bodies were decently removed; and the miniſters of the church were permitted to convey the remains of St. Babylas to their former habitation within the walls of Antioch. The return of the ſaint was a triumph; and the triumph was an inſult on the religion of the emperor, who exerted his pride to diſſemble his reſentment. During the night which terminated the proceſſion that accompanied the removal of the relics of St. Babylas, the temple of Daphne was in flames; the ſtatue of Apollo was conſumed; and the walls of the edifice was left a naked and awful monument of ruin. It was ſaid, however, by the Chriſtians at Antioch, that the powerful interceſſions of St. Babylas had pointed the lightnings of heaven againſt the devoted roof; but Julian aſcribed the fire of Daphne to the revenge of the Galilæans. For the diſcovery of the criminals ſeveral eccleſiaſtics were tortured; and a preſbyter of the name of Theodoret was beheaded by the ſentence of the count of the Eaſt. But this haſty act was blamed by the emperor, who lamented, with real or affected concern, that the imprudent zeal of his miniſters would tarniſh his reign with the diſgrace of perſecution. Gibbon's Hiſtory, vol. iv.

Daphne, *Fountain of*, a fountain of Judæa, in the tribe of Naphtali. According to Steph. Byz. there was a town called Daphne in Lycia.—A ſea-port on the Euxine ſea had alſo this name.

Daphne, in *Mythology*, a nymph with whom Apollo is ſaid to have had an amour. Whilſt he was in purſuit of her, it is ſaid that ſhe was transformed into a laurel. The name is ſaid to be derived from Δαφονεω, *voco*, becauſe the laurel makes a crackling noiſe while it burns. The fable of the amours of Apollo and Daphne, is thus accounted for by Banier. Some prince, called Apollo, on account of his love of the belles lettres, falling in love with Daphne, the daughter of Peneus, king of Theſſaly, and being one day in purſuit of her, the young princeſs died upon the banks of a river in ſight of her lover. Some laurels ſpringing up on that ſpot gave riſe to her metamorphoſis; or rather the etymology of Daphne's name, which in Greek imports a laurel, was the foundation of the fable.

DAPHNELÆON, in *Medicine*, Δαφνελαιον (from δαφνη, the *bay-tree*, aud ελαιον, oil), *laurinum*, or oil of bay. This is prepared of the berries, when full ripe and ready to fall off, by boiling them in water; by which they tranſmit through their huſks a fat ſubſtance, which, after compreſſing the berries with the hand, is taken off with ſhells. Some, after they have inſpiſſated oil of unripe olives with cyperus, juncus odoratus, and calamus, caſt therein the tender leaves of the bay, and boil them together; and others add the berries, until it ſmells ſufficiently ſtrong; and ſometimes ſtyrax and myrrh are mixed with them. The mountainous and broad-leaved bay is the fitteſt for the preparation of this oil, which is beſt of its kind when recent, of a green colour, very bitter and acrimonious.

DAPHNEPHORIA, Δαφνηφορια, in *Antiquity*, a novennial feſtival, celebrated by the Bœotians in honour of Apollo.

At this feſtival a globe of braſs was ſet upon a branch of olive, from which hung ſeveral other ſmall globes; the firſt repreſented the ſun or Apollo; the ſecond, ſomewhat leſs in ſize, repreſented the moon; and the reſt, the ſtars. Crowns which encircled theſe globes pointed out the days of the year. This branch, with all its ornaments, was carried about in proceſſion by a young man, who held likewiſe in his hand a laurel-bough, and thence had the name "Daphnephoros." This youth, according to Pauſanias (in Bœot.), was to be choſen out of the beſt families, and to be well-formed, vigorous, and robuſt.

DAPHNOMANCY, from δαφνη, *laurel*, and μαντεια, *divination*; a kind of divination practiſed by throwing branches of laurel into the fire: the crackling of them was deemed a favourable omen; the contrary, otherwiſe. The leaves of laurel were alſo chewed, in order to communicate the gift of prophecy.

DAPHNUS, in *Ancient Geography*, a part of the canal of Conſtantinople, at the diſtance of 80 ſtadia from this city, and 40 ſtadia from the Euxine ſea. Arrian.—Alſo, a town of Lower Egypt, ſeated on a branch of the Nile, on the route from Peluſium to Memphis.—Alſo, a fort on the Danube, conſtructed by the emperor Conſtantine; and after being demoliſhed by the barbarians, repaired by the emperor Juſtinian.—Alſo, baths in Sicily, near Syracuſe.—Alſo, a ſea-port of Ethiopia, on the Arabic gulf.—Alſo, a town of the Opuntian Locrians, ſituated on the ſea-coaſt, near the frontiers which ſeparated the Opuntians from the Epicnemidian Locrians. It formerly belonged to the Phocæans.—Alſo, a river of Aſia Minor, in Caria.

DAPHNUSA,

DAPHNUSA, an iſland of the Ægean ſea, placed by Pliny near thoſe of Samos and Leſbos.

DAPHNUSIS, a lake of Aſia Minor, in Bithynia.

DAPHTHITÆ, a people of Africa, placed by Ptolemy in the interior of Libya, at the foot of mount Atlas.

DAPIFER, the dignity or office of grand-maſter, or grand-ſewer, of a king's or prince's houſehold.

The word is pure Latin, compounded of *daps*, *dapis*, a diſh of meat ſerved on the table, and *fero*, I bear; ſo that dapifer literally ſignifies a diſh-carrier, or an officer who ſerves the meats upon the table.

The title of dapifer was given by the emperor of Conſtantinople to the czar of Ruſſia, as a teſtimony of favour. In France, the like office was inſtituted by Charlemagne, under the title of dapiferat, and ſenechauſſe; to which was affixed the ſuperintendance over all the officers of the houſehold.

In England the office of dapifer was leſs eminent; being found in ſeveral of our ancient charters named one of the laſt of the officers of the houſehold.

The dignity of dapifer is ſtill ſubſiſting in Germany. Till the year 1623, the elector palatine was dapifer, or grand-ſewer of the empire: ſince that time, the elector of Bavaria has aſſumed the title of arch-dapifer of the empire. His office is, at the coronation of an emperor, to carry the firſt diſh of meat to table on horſeback.

The ſeveral functions of a dapifer occaſioned the ancients to give him divers names: as, ελειατρος, and eleater, dipnocletor, convocator, trapezopæus, architriclinus, proguſta, præguſtator, domeſticus, megadomeſticus, œconomus, majordomus, ſeneſchallus, ſchalus, gaſtaldus, aſſeſſor, præfectus, or præpoſitus menſæ, princeps coquorum, et magirus.

DAPIFERAT, DAPIFERATUS, the office of DAPIFER.

DAPPLE, in *Rural Economy*, a term uſed to ſignify marked with different colours as applied to animals; thus we have in horſes dapple, or dappled bays and grays.

DAPPLE *bay*, in the *Manege*, is uſed for a horſe which has marks of a dark bay colour. Such are alſo called bays à mirroir.

DAPPLE *black*, a black horſe, having ſpots or marks blacker and more ſhining than the reſt of his ſkin.

DAPS, in *Geography*, a river of Denmark, which runs into the Little Belt; 14 miles north-eaſt of Haderſleben.

DAPSILES CORONÆ, among the Romans, a kind of crowns or garlands worn by the women, which covered their faces, and ſerved as a veil.

DARA, in *Ancient Geography*, a river of Aſia, in Caramania, which falls into the Perſian gulf; called by Pliny *Daras*.—Alſo, a river of Africa, which diſcharged itſelf into the Atlantic ocean, called by Ptolemy *Daratis*, and ſuppoſed to be the river Senegal of modern times.

DARA, a fortified town of Aſia in Meſopotamia, 14 miles from Niſibis, and four days' journey from the river Tigris, was peopled and adorned by the emperor Anaſtaſius, from whom it derived the name of *Anaſtaſiopolis*. Dara has been amply deſcribed by Procopius, who ſays that it was traverſed by the river Cordes. The haſty works conſtructed in this place, by order of Anaſtaſius, were improved by the perſeverance of Juſtinian; and as a ſpecimen of the military architecture of that age, we ſhall give a brief deſcription of it.

The city was ſurrounded with two walls, and the interval between them of 50 paces afforded a retreat to the cattle of the beſieged. The inner wall was a monument of ſtrength and beauty; it meaſured 60 feet from the ground, and the height of the towers was 100 feet; the loop-holes, from which an enemy might be annoyed with miſſile weapons, were ſmall, but numerous; the ſoldiers were planted along the rampart, under the ſhelter of double galleries, and a third platform, ſpacious and ſecure, was raiſed on the ſummit of the towers. The exterior wall appears to have been leſs lofty, but more ſolid; and each tower was protected by a quadrangular bulwark. A hard rocky ſoil reſiſted the tools of the miners; and on the ſouth-eaſt, where the ground was more tractable, their approach was retarded by a new work, which advanced in the ſhape of an half-moon. The double and treble ditches were filled with a ſtream of water; and in the management of the river, the moſt ſkilful labour was employed to ſupply the inhabitants, to diſtreſs the beſiegers, and to prevent the miſchiefs of a natural or artificial inundation. Dara continued more than 60 years to fulfill the wiſhes of its founders, and to provoke the jealouſy of the Perſians, who inceſſantly complained, that this impregnable fortreſs had been conſtructed in manifeſt violation of the treaty of peace between the two empires. When Choſroes, the Perſian monarch, aſſumed the guard of the gates of Caucaſus, he ſuſpended the demolition of Dara, on condition that it ſhould never be made the reſidence of the general of the Eaſt. In his laſt wars with the Romans, A. D. 572, &c., Choſroes conducted in perſon the ſiege of Dara; and although that important fortreſs had been left deſtitute of troops and ma gazines, the valour of the inhabitants reſiſted above five months, the archers, the elephants, and the military engines of the great king. During the reign of Choſroes II., the ſtrong cities of Martyropolis and Dara were reſtored to the Romans; and the Peſarmenians became the willing ſubjects of an empire, the eaſtern limit of which was extended, beyond the example of former times, as far as the banks of the Araxes, and the vicinity of the Caſpian.

DARA, or *Dra*, in *Geography*, a large river of Africa, which riſes in the Greater Atlas, not far from Teſza, and diſcharges itſelf into the Atlantic, not far from Cape Non, encloſing a great part of the country called Mauritania Cæſarienſis.

DARA, or *Dra*, a province of the kingdom of Morocco, ſo called from the river Dara, which paſſes through it, and comprehending, according to ſome modern authors, a great part of Biledulgerid. It is bounded on the north by the provinces of Morocco, Gezula, and Tafilet, on the eaſt and ſouth by Sahara, and on the weſt by Sus. Some have eſtimated its length at about 100 leagues. It contains a number of caſtles, forts, and ſtrong holds along the banks of the Dara. One of the chief towns is Beniſabih, or Macabah, not far from which is Quiteoa, about 200 paces from the river, well defended by walls, and fortified by a citadel. Near this town is Tozarin, and at the diſtance of about 20 leagus from Quiteoa is Tayamadert. On the banks of the Dara are Turzela and Margala; the former of which is ſaid to contain 4000 houſes, a caſtle, and above 400 Jewiſh families. Yinzulin is the largeſt town of the province, ſituated about 12 leagues from Jaragala, and ſtrongly fortified by a citadel and walls. Timeſguit, another of its towns, is ſituated on the confines of Gezula, and contains within its walls about 3000 houſes, according to La Croix, and about 200 families in the ſuburbs. The province of Dara is generally barren, though ſome parts of it produce grain, eſpecially after the overflow of its river. The whole province depends for the ſubſiſtence of its inhabitants, on corn and other neceſſaries procured at Fez, in exchange for its indigo and dates. The inhabitants who are Arabians and Mahometans, are for the moſt part of a very dark complexion, which is aſcribed to their frequent alliances with the Negroes. The women, though ſome-

what corpulent, are reckoned handſome; and their general diſpoſition is mild, and leſs ſavage than that of other females of the country. Some diſtricts of the country are dependent on the emperor of Morocco, to whoſe ſovereignty Dara is ſubject, though they are governed by their own ſcheiks.

DARAAN, or DARAUN, a town of Aſia, in Great Tartary; about 24 leagues E. of Samarcand.

DARABA, in *Ancient Geography*, a town of Ethiopia, placed by Strabo on the other ſide of the foreſt of Cumania, and in the vicinity of the country belonging to the people called Elephantophagi.

DARABGERD, or DARABGUIERD, in *Geography*, a town of Perſia, in the province of Farſiſtan, ſaid to have been founded by Darius; it is large, but not populous; and near it is found ſalt of various colours, white, black, red, and green. A conſiderable manufacture of glaſs is carried on in this place: 116 miles E S.E. of Schiras.

DARABITTA, in *Ancient Geography*, a village of Paleſtine, at the extremity of Galilee. Jonathan paſſed through it in his way from Tiberias to Jeruſalem.

DARADÆ, a people of Africa, in the interior of Libya, placed by Ptolemy on the coaſt of the weſtern ocean, in the environs of the river Daratis. Pliny calls them *Daratitæ*.

DARADAX, a river of Aſia, in Syria. We learn from Xenophon, that Beleſis, governor of Syria, had a large and beautiful park, and alſo a palace, near the ſource of this river. Cyrus cauſed the trees of the park to be cut down, and ſet fire to the palace.

DARADI, a people of Africa, in the interior of Ethiopia.

DARADUS, a river of Libya Interior.

DARAE, a people of Africa, in Libya, who formed a part of the Getulians, and inhabited a diſtrict very remote from the ſea.

DARAIA. See HANIFA.

DARAMAJON, a town on the north-weſt of the iſland of Java; 30 miles E. of Batavia.

DARAMPOORY. See DAREMPOORY.

DARAN, JAMES, in *Biography*, a French military ſurgeon, who acquired much celebrity for his ſkill in treating diſorders in the urethra, particularly for his improved method of making bougies, publiſhed in 1745, "Recueil d'Obſervations Chirurgicales ſur les Maladies de l'Urethra. It has been ſeveral times reprinted, and, in 1750, was tranſlated into Engliſh by Mr. Tomkyns, an eminent ſurgeon of London, who was able, he ſays, from his own experience, to atteſt the ſuperior utility of Daran's bougies over thoſe that had been commonly uſed. In the fifth volume of the "Journeaux de Medicine," there is a communication by Daran, in which he makes mention of a tube he had invented for drawing off the urine. This he deſcribes more particularly in his "Treatiſe on the Gonorrhœa Virulenta," firſt publiſhed in 1756. It is a flexible catheter, formed of a ſpiral wire, covered with the ſame compoſition as that uſed in making the bougies, and was capable of being introduced into the bladder, in many caſes, where it would have been dangerous, often impoſſible, to uſe the common catheter. Conſiderable improvements have been ſince made of this inſtrument, but the merit of the invention ſtill remains with Daran. Haller Bib. Chirurg.

DARANI, in the *Materia Medica*, a word uſed by ſome of the old writers to expreſs the ſal ammoniac of the times, which was the ſame with our ſal gemmæ.

DARAPORUM, in *Geography*, a town of Hindooſtan, in the Coimbetore country, 36 miles E.S.E. of Coimbetore, and 73 W. of Tritchinopoly. N. lat. 10° 42'. E. long. 77° 40'.—Alſo, a river of the ſame country, which has its ſource from an elevated plain about 60 miles in extent, which ſtretches acroſs the eaſtern mouth of the gap or valley encloſed between the branches of the Gauts, and riſes ſuddenly like a vaſt terrace, from the level of the ſurrounding country.

DARAPTI, in *Logic*, a mode of ſyllogiſm in the third figure, wherein the major and minor are univerſal affirmative propoſitions, and the concluſion a particular affirmative, E. gr.

DA "Every truly religious man is virtuous."
RA "Every truly religious man is hated by the world."
PTI "Therefore, ſome virtuous men are hated by the world."

DARBY, in *Geography*, a ſmall town in Delaware county, Pennſylvania, on the E. ſide of Darby creek, containing about 50 houſes and a Quaker meeting-houſe, and lying 7 miles S.W. by W. of Philadelphia. There are two townſhips of this name in the county, called Upper and Lower, from their relative ſituation.

DARDA, a town and fortreſs of Hungary, built by the Turks in the year 1686, and taken by the Imperialiſts in 1687; 30 miles S. of Bacs, and 44 S.S.E. of Zinget.

DARDANARIUS, *Uſurer*, *Monopoliſt*; a name anciently attributed to ſuch as cauſed a ſcarcity, and dearneſs of proviſions, particularly corn, by buying and hoarding it up to raiſe its value, and ſell it again at an extravagant rate.

The name Dardanarius was given from one Dardanus, who is ſaid to have made a practice of ſpoiling and deſtroying the fruits of the earth by a ſort of ſorcery. Hof. Lex. in voc.

The ſame people are alſo called æruſcatores, directarii, ſitocapeli, annonæ flagellatores, and ſeplaſiarii.

DARDANELLES, STRAITOF, in *Geography*, is ſituated 50 leagues to the weſt of Conſtantinople, between the Archipelago and the little ſea of Marmora, and extending from the coaſt of Troy to Gallipoli over againſt Lampſacus. This ſpace, about 12 leagues, of an unequal breadth, contains different points, in which the continents of Europe and Aſia, which this ſtrait ſeparates, approach to within the diſtance of three or four hundred fathoms. Three leagues from its mouth, on the ſide next the Archipelago, at the narroweſt part of the ſtrait, have been built in the year 1658, by Mahomet IV., the two caſtles called the Dardanelles; the cannon of each of which commanded the oppoſite ſhore. Theſe were, for a long time, the only barrier to ſecure Conſtantinople; but the Turks, becoming more fearful, though not more enlightened, built two others near the mouth; but as they are at the diſtance of 1500 fathoms, their fire is uncertain, and their defence inſufficient.

DARDANI, in *Ancient Geography*, a people of Illyria in Dalmatia, who inhabited the country called *Dardania*.

DARDANIA, a country of Aſia Minor, in the northern part of the Troade, when the kingdom of Troy ſubſiſted; but when this country was otherwiſe divided, it formed a part of the leſſer Myſia. It lay between the Helleſpont and the ſources of the Granicus. It took its name from Dardana, Dardania, or Dardanus, its capital; and its inhabitants were called *Dardanii* or *Dardanidæ*.—Alſo, a country of Illyria, in Dalmatia; the capital of which bore the ſame name.—Alſo, a name given to Mœſia Superior, on the ſide of the mountains which ſeparate this province from Macedonia Salutaris. Theſe mountains abounded with mines and mineral waters. Dardania was bounded on the eaſt by Pæonia, on the ſouth by Pelaconia, on the weſt by Dalmatia, and on the north by Dacia Ripenſis. In proceſs of time, they gave to this country the name of *Dacia Mediterranea*.—Alſo, a town

of

of Aſia Minor, in the Troade, called *Dardana*, or *Dardanus*. This town, the capital of Dardania, was ſituated on the ſea-coaſt, near the Helleſpont, 16 miles from Troy, 8 miles N. from Abydos, and 8 miles S. from Rhetœum. It is pretended that it was founded by Dardanus, who had married the daughter of Teucer, king of this country; and Steph. Byz. ſays, that it had been called Teucris. In this city, as Plutarch ſays, peace was concluded between Mithridates and Sylla, the Roman general. This town gave name to the *Dardanelles*.

DARDANIS, a town of Africa, in the Pentapoli, placed by Ptolemy on the frontiers of Marmarica, near the promontory Zephyrium.

DARDANIUM Promontorium, a promontory of the Troade.

DARDANUS. See Dardania.

Dardanus, a town of Italy, which, according to Lycophron, was ſurrounded by the waters of the marſh of Salpé.—Alſo, a town of Macedonia, mentioned by Lycophron, probably the ſame with Dardania in Illyria.—Alſo a mountain of Spain in the Tarragoneſe territory; ſuppoſed to be the moden *La Penna de Orduna*.

DARDESSEN, or Dardesheim, in *Geography*, a ſmall town of the kingdom of Weſtphalia, in the former principality of Halberſtadt, which, till the peace of Tilſit in July 1807, belonged to the kings of Pruſſia. It is ſituated on an eminence called the Ortſberg, from which there is a capital view of the Hercynian foreſt or the Hartz, and which is famous for quarries of excellent free-ſtone.

DARE. See Dace and Fishing.

DAREA, in *Botany*, a genus of dorſiferous ferns, named by Juſſieu in honour of Mr. Dare, an Engliſh botaniſt of the time of Ray, one of the firſt who found the *Hymenophyllum tunbridgenſe*, Engl. Bot. v. 3. t. 162. Bergius, who firſt diſtinguiſhed this genus, which we now call *Darea*, denominated it *Cœnopteris*, a *new fern*, a name to which we object, not only for its being compounded of another generic name previouſly eſtabliſhed, *Pteris*, which objection, though founded in Linnæan principles, ſeems in danger of being overruled; but even more on account of its abſurdity. See Sm. Introd. to Bot. 388. Dr. Swartz, however, has retained *Cœnopteris*, perhaps thinking himſelf obliged in ſome degree to do ſo, out of reſpect to its author, the founder of the new profeſſorſhip at Stockholm, which he himſelf ſo worthily fills. We alſo entertain very high reſpect for the botanical merits of Bergius, though few authors have been ſo peculiarly unfortunate in the conſtruction of generic names. We think alſo that the authority of Juſſieu, as a leading ſyſtematic writer, may, though ſubſequent to that of Bergius, be preferred to it. Juſſ. Gen. Pl. 15. Sm. in Mem. de l'Acad. de Turin, v. 5. 409. Tracts 233. (Cœnopteris. Berg. in Act. Nov. Petrop. v. 6. part. alt. 248. Sw. Fil. 87. Thunb. Prod. 172.). Claſs and order, *Cryptogamia Filices*; ſect. *Annulatæ*. Nat. Ord. *Filices dorſiferæ*.

M. de Juſſieu, G. Pl. 447, by an accidental error, refers the *Cœnopteris* of Bergius to his *Myriotheca*, which is the *Marattia* of Swartz, but their characters are too different to cauſe any confuſion.

Eſſ. Char. *Capſules* in ſcattered lines. *Cover* originating laterally from a vein, and ſeparating outwards. The habit of this genus is firm, ſmooth, abundant in ſlender ſubdiviſions. Cover linear, membranous, entire, pale or browniſh. Capſules each embraced by a jointed ring. Its eſſential character is juſt the reverſe of that of *Aſplenium*, whoſe cover opens inwardly, that is, always towards a rib or vein, and the habits of theſe two genera are ſo different as to prove this a moſt ſolid diſtinction.

Sp. 1. D. *flaccida*. (Aſplenium flaccidum; Forſt. Prod. 80. Cœnopteris flaccida; Thunb. in Act. Nov. Petrop. v. 9. 159. t. D. f. 1, 2.) Frond looſely pinnate. Leaflets alternate, ſtalked, lanceolate pinnatifid; ſegments linear, uniform, undivided. Found by Forſter at Duſky bay in New Zealand. *Frond* ſmooth, lax, of a pale green, ſomewhat glaucous, two feet or more in height, lanceolate, with a long *ſtalk*, looſely pinnated. *Leaflets* on ſlightly bordered ſtalks; two or three of the lower pairs oppoſite; the reſt alternate; all lanceolate, pointed, long, pinnatifid, ſerrated at the point; ſegments alternate, linear. *Lines* of fructification ſolitary, running along the lower part of the inner edge of each ſegment; their *cover* originating from its midrib, and reaching nearly to the margin, ſomewhat revolute when ripe. *Capſules* ſmall, very numerous. 2. D. *auriculata*. (Cœnopteris auriculata; Sw. Fil. 87. Act. Nov. Petrop. v. 9. t. E. f. 2.) Frond pinnate, lanceolate. Leaflets oblong, obtuſe, cut; ſegments linear; the lowermoſt cloven, auricled. Sw. A native of the Cape of Good Hope. 3. D. *odontites*. (Cœnopteris odontites; Sw. Fil. 87. Act. Nov. Petrop. v. 9. t. E. f. 1.) Frond doubly pinnatifid. Segments lanceolate, acute, the lowermoſt cloven. Sw. A native of the Cape of Good Hope. 4. D. *rutæfolia*. (Cœnopteris rutæfolia; Berg. in Act. Nov. Petrop. v. 6. 249. t. 7. f. 2. Adiantum furcatum; Linn. Suppl. 447, excluſ. ſyn.) Frond pinnate. Leaflets once or twice pinnatifid; ſegments linear-lanceolate. Main-ſtalk ſcarcely winged. A native of the Cape of Good Hope. *Frond* two feet or more in height, ſmooth, pale, lanceolate, alternately pinnate. *Stalk* ſmooth, ſcarcely winged or bordered even at the very top. *Leaflets* ſtalked, two or three inches long, broadeſt at the baſe; doubly pinnatifid in their lower part, ſimply pinnatifid upwards; ſegments all uniform, and as nearly as poſſible of an equal ſize, linear-lanceolate, ſlightly incurved, entire, with a ſhortiſh *line* of fructification about the middle of their inner edge. 5. D. *furcata*. (Cœnopteris furcata; Berg. in Act. Nov. Petrop. v. 6. 249. t. 7. f. 1. Adiantum borbonicum; Jacq. Coll. v. 3. 286. t. 21. f. 1.) Frond pinnate. Main-ſtalk winged. Leaflets pinnatifid; their lowermoſt lobes ſubdivided; ſegments obovato-lanceolate, obtuſe. A native of the iſle de Bourbon. Swartz unites this with the laſt, but it appears to us diſtinct. It is indeed but half ſo large, which might account for its *frond* being leſs compound; but it differs eſſentially in having the principal ſtalk winged all the way up, and its ultimate ſegments are all ſhorter, blunter, and rather obovate than lanceolate. Each *line* of capſules is alſo much ſhorter, its length being ſcarcely twice its breadth. 6. D. *pectinata*. Frond pinnate. Main-ſtalk winged upwards. Leaflets crowded, nearly oppoſite, pinnatifid; ſegments lanceolate, obtuſe, the lowermoſt palmate. For this beautiful ſpecies we are obliged to Mr. Menzies, who found it in the Sandwich iſlands. It is of a richer green than the foregoing. *Frond* linear-lanceolate, a foot high, with a ſhort ſtalk. *Leaflets* numerous, crowded, nearly if not quite oppoſite, ſcarcely above an inch long, linear-lanceolate, bluntiſh, cut into ſeveral lanceolate bluntiſh ſegments; all ſimple, except here and there one which is ſlightly cloven, and the firſt at the baſe of each leaflet at its upper edge, which is palmate. *Lines* rather longer, and much narrower, than in the laſt. 7. D. *vivipara*. (Cœnopteris vivipara; Berg. in Act. Nov. Petrop. v. 6. 250. t. 7. f. 3. Sw. Fil. 89. Acroſtichum viviparum; Linn. Suppl. 444.) Frond doubly

bly pinnate. Leaflets linear-lanceolate, acute, ſimple, cloven, palmate or pinnatifid. Gathered by Sonnerat in the iſles of Mauritius and Bourbon, and communicated by Thouin to the younger Linnæus, who candidly obſerves that "it but ill agrees with the generic character of *Acroſticum*, but that its fructification comes forth as in A. *ſeptentrionale* and *auſtrale*." This is correct, if the direction in which the cover ſeparates be overlooked, and this no one had then thought of. The *frond* has a broadiſh-lanceolate, pointed form, and is doubly pinnate. Its primary diviſions are oppoſite, ſomewhat crowded, linear-lanceolate, taper-pointed, ſubdivided into numerous alternate *leaflets*, of which the uppermoſt are linear-lanceolate, acute, undivided; the next cloven; thoſe ſtill nearer the baſe palmate or pinnatifid, all the ſegments being uniform. *Lines* ſolitary in each leaflet or ſegment, very long and narrow. Sometimes the ſeeds germinate upon the plant, and the inverſely-heart-ſhaped ſeed lobes are very apparent. 8. D. *cicutaria*. (D. tripinnata; Cav. Leccion. 259? Cœnopteris cicutaria; Sw. Fil. 88. Aſplenium cicutarium; Sw. Prod. 130. A. criſtatum; La Marck Encycl. v. 2. 310. Filix pinnulis criſtatis; Plum. Fil. 34. t. 48 A. Petiv. Fil. t. 5. f. 8. Rutæ murariæ accedens filicula, &c.; Sloane Jam. v. 1. 92. t. 52. f. 3.) Frond doubly pinnate. Leaflets crowded, pinnatifid and palmate, ſomewhat wedge-ſhaped; ſegments elliptical, obtuſe. Not rare in Jamaica, or other Weſt Indian iſlands. *Frond* from one to two feet high, dark green, doubly pinnate in an alternate order. *Leaflets* ſomewhat ovate or obovate, very much crowded, pinnatifid or palmate, eſpecially the firſt ſegment of each leaflet, which is broad and wedge-ſhaped; the reſt are elliptical inclining to lanceolate, and obtuſe. *Lines* ſhortiſh, brown. 9. D. *microphylla*. Frond doubly pinnate. Leaflets doubly pinnatifid; ſegments uniform, linear. Cover jagged. Brought by Mr. Menzies from the Sandwich iſlands. The *frond* is three feet or more in height, far more compound than in any other known ſpecies; inſomuch that each conſiſts, at a very moderate computation, of at leaſt a million of ſegments; and as ten capſules, if not more, may be reckoned to each ſegment, one with another, the quantity of ſeeds produced by each plant will be found ſo immenſe, that if they and their offſpring were to increaſe for a few years at the ſame rate, the land of the whole globe would be covered with this fern, as, according to Linnæus's computation, the offſpring of one haddock would in twenty years fill up the whole ocean. The principal diviſions of the *frond* very much reſemble the leaves of *Achillea millefolium*. They are alternate, and alternately pinnate, each *pinna* being in like manner doubly and deeply pinnatifid, of a dark green; the ultimate ſegments uniform, about a line in length, linear, or ſomewhat lanceolate, bluntiſh, often with a minute curved point. *Dots* dark brown, chiefly on the lowermoſt ſegments. *Covers* broadiſh, tranſparent, brown, jagged or criſped. 10. D. *rhizophylla*. (Cœnopterus rhizophylla; Sm. Pl. Ic. ex Herb. Linn. t. 50. Sw. Fil. 88.) Frond doubly pinnate, taking root at the point. Leaflets ſtalked, obovate, ſomewhat falcate; the lowermoſt lobed. Gathered in Hiſpaniola, by M. Thierry de Menonville. *Frond* a ſpan long, darkiſh-green, lanceolate, taking root by the naked point of its ſtalk, alternately doubly pinnate, ſmooth. *Leaflets* on ſhortiſh ſtalks, rather diſtant, broad, obovate, obtuſe, ſomewhat falcate or curved, now and then obſcurely notched, the lowermoſt eſpecially lobed. *Dots* broad and ſhort, ſolitary towards the baſe of each leaflet at its upper edge. Dr. Swartz now refers Sloane's t. 52. f. 3. to this ſpecies, which we are confident he had originally cited with much more propriety under D. *cicutaria*, which it repreſents in a young and barren ſtate. 11. D. *myriophylla*. (Cœnopteris myriophylla; Sw. Fil. 88.) Frond twice or thrice pinnate. Stalks winged. Leaflets obovate, obcordate, or lobed. Gathered in Jamaica by Dr. Swartz, one of whoſe ſpecimens has been given us by Mr. Menzies. It is ſmaller than the laſt, and of a pale green, appearing curiouſly ſpeckled under the microſcope. *Stalks*, both general and partial, all equally winged, and twice or thrice compounded in an alternate manner. *Leaflets* a line or rather more in length, ſtalked, obovate, obtuſe, entire, keeled, ſometimes cloven ſo as to be inverſely heart-ſhaped, more rarely three-lobed. *Lines* pale brown. The name of this ſpecies would have been much more applicable to our D. *microphylla*, had it not been pre-engaged. 12. D. *heterophylla*. Frond deeply pinnate. Barren leaflets rhomboid, cut and ſerrated; fertile ones ſuperior, deeply pinnatifid; their ſegments linear; ſometimes forked. A native of New South Wales, near Port Jackſon, from whence we received it through the hands of the late R. Moleſworth, eſq. It is one of the fineſt and moſt remarkable of its genus. *Frond* about two or three feet high, of a paliſh, ſomewhat glaucous green, ſmooth, broad, doubly and alternately pinnate. The lower *leaflets*, till towards the middle of the frond, are barren, above an inch long, of a broad lanceolate figure, inclining to rhomboid; dilated, lobed, and approaching to auricled, at their baſe; their margin jagged and ſerrated: all the upper leaflets of the ſame dimenſions, but very deeply pinnatifid, their ſegments alternate, linear, acute, entire, ſome of the lower ones occaſionally cloven or forked. The upper edge of each ſegment is almoſt entirely occupied by a long *line* of fructification, whoſe reflexed, ſmooth, whitiſh *cover* is very conſpicuous. *Capſules* very numerous, brown. S.

DAREC, in *Geography*, a town of Perſia, in the province of Segeſtan; 60 miles S. of Zareng.

Darec *de Camuna*, a town of Perſia, in the province of Mecran; 180 miles W. of Kidge.

DAR-El-Hamara, a town of Africa, in the kingdom of Fez, ſaid to have been built by the Romans; the trade of which conſiſts principally in corn and oil. N. lat. 34° 20′. W. long. 8° 46′.

DAREMMA, in *Ancient Geography*, a town of Aſia, placed by Ptolemy in the interior of Meſopotamia.

DAREN, in *Geography*, a river of Wales, in the county of Caernarvon, which runs into the ſea; 15 miles S.W. of Pwllhely.

DARENT, a river of England, in the county of Kent, which runs into the Thames, 3 miles N. of Dartford. The mouth near the Thames is called *Dartford Creek*.

DAREW, a town of Lithuania, in the palatinate of Novogrodek; 34 miles S.S.E. of Novogrodek.

DAR-FUR, a country in the interior part of Africa, extending, according to Mr. Browne's map, from about 11° to 15° 20′. N. lat. and in its greateſt breadth from about 26° to 29° 15′. E. long. The capital of this country is *Cobbé*; which ſee. The other towns of principal note are Sweini, Kûrma, Cubcabia, Rîl, Cours, Shoba, Gidid, and Gellé. Sweini is ſituated almoſt north of Cobbé, at the diſtance of more than two days' diligent travelling. Kûrma, or Kourma, is a ſmall town, W. by S., at the diſtance of $4\frac{1}{2}$ or 5 hours, 12 or 13 miles. Cubcabia, a more conſiderable place, is nearly due weſt, at the diſtance of $2\frac{1}{2}$ days. Cours, a place of little note, N.W. by W. at $5\frac{1}{2}$ hours travelling from Cobbé. Rîl is ſomewhat more than three days removed from it, in the direction S.S.E., or about 60 miles. Shoba is $2\frac{1}{2}$ days from Cobbé. Gidîd is nearly S.E., and about $1\frac{1}{2}$ day from Cobbé. Gellé is not far from Cubcabia, but ſome hours further removed to the ſouth. (See the reſpective

tive articles.) The perennial rains, which fall in Dar-Fûr, from the middle of June till the middle of September, in greater or leſs quantity, but generally both frequent and violent, ſuddenly inveſt the face of the country, which was before dry and ſterile, with a delightful verdure. As ſoon as the rain begins, the proprietor, and all the aſſiſtants he can collect, go out to the field, and having made holes at about two feet diſtance from each other, with a kind of hoe, the *dohn* is thrown into them, and covered with the foot. The time for ſowing the wheat is nearly the ſame. The *dohn* remains nearly two months before it is ripe; the wheat about three. Wheat is ſcarce, and as the preſent ſultan forbids the ſale of it till he is ſupplied, it is with difficulty procured by purchaſe. The *mahrick*, or greater *kaſſob*, which is a larger grain than the *dohn*, is common, and a ſmall quantity of ſeſamum is ſown. Their beans are different from ours; and in their gardens are *bamea*, *meluchia*, lentils (*adis*), kidney beans (*lubi*), and ſome others. The water-melons, and that called at Cairo *abd-el-awi*, together with ſome other kinds, abound during the wet ſeaſon, and even before, if they be watered. Wood is found abundantly in this country; and there are ſeveral ſpecies of trees, but none that produce fruit worth gathering, unleſs it be the tamarind. The dates are few, and their fruit ſmall, dry, and deſtitute of flavour. Indeed this tree ſeems not indigenous in the country, but to have been tranſported thither from the neighbourhood of the Nile, Dongola, Sennaar, &c. The quadrupeds, or at leaſt the diſtinct ſpecies of them, are not very numerous. The only good horſes which the inhabitants of this country poſſeſs, are bred in the country of Dongola, and by the Arabs E. of the Nile. The Arabs feed them with milk, and they are ſeldom caſtrated. None of the horſes of Soudân are ſhod. Two or three diſtinct ſpecies of ſheep (*ovis aries*) exiſt in Soudân. Their meat is not ſo good as that of the Egyptian ſheep. They are covered with coarſe wool, reſembling hair, and apparently unfit for any manufacture. The goats (*capræ cerviciporæ*) are more numerous than the ſheep, and their fleſh is cheaper; they are not very different from thoſe of Egypt, but ſomewhat larger. The aſs reſembles that of Great Britain, in its form, and indocile nature. The only good ones are brought by the Jelabs from Egypt; but they are not much uſed for riding. The bull is ſometimes caſtrated; but of the animals ſlaughtered in the market, the emaſculated are feweſt in number; nor is any preference manifeſted to the one above the other as an article of food. The horned cattle, fed by the tribes in the vicinity of the rivers, amount to a great number, and the tribute paid on their account to the monarch forms a valuable part of his revenue. The beef is good. Cows are alſo abundant; but their milk is not very palatable; ſome of the ſettlers make of it a kind of cheeſe; but the inhabitants are not generally acquainted with that proceſs. The camels of Fûr are of a mixed breed, and are found of all colours and ſizes. Thoſe that are brought directly from the weſt or ſouth are large, ſmooth-haired, and in colour moſt frequently approaching to white, or light brown. Many of thoſe of Kordofân are black; and they are leſs docile than the others. There are few countries where this animal abounds more than in Dar-Fûr. When the male camel is unruly, they ſometimes deprive him, by a cruel operation, of one or both of his teſticles. The fleſh of the camel, particularly the female, which is fattened for the purpoſe, is much uſed for food, and the milk is alſo much eſteemed. The camels of Fezzan, and other weſtern countries, are reckoned for labour ſuperior to thoſe of Fûr, and fetch a higher price. The former are larger, and able to carry a greater burden, but leſs capable of enduring thirſt. Soudân affords many fine dromedaries; but thoſe of Sennaar are moſt celebrated. It is ſaid, that, in travelling, they will proceed at the rate of 10 miles an hour, for 24 hours.

The dogs of Dar-Fûr are of the ſame kind with thoſe of Egypt; the common houſe-cat is ſcarce; and it is ſaid there are none beſides thoſe which were brought originally from Egypt. They are of the ſame kind with ours. The wild or ferocious animals are, principally, the lion, the leopard, the hyæna, the wolf, the jackal, and the wild buffalo; but they are not commonly ſeen in the cultivated parts of the empire, except the hyæna and the jackal, which come in herds of ſix, eight, and often more, into the villages at night, and are very rapacious. They will kill dogs and aſſes, even within the houſes; nor are they greatly alarmed at the ſight of a man or the ſound of fire-arms. The people of the country dig pits for them, and lying in ambuſcade, when one is entrapped, ſtun him with clubs, or pierce him with their ſpears. The jackal is harmleſs, but his hideous cry ſounds to a great diſtance. To the animals already enumerated we may add the elephant, the rhinoceros, the camelopardalis, the hippopotamus, and the crocodile. Elephants are ſeen in large herds of four or five hundred, and it is ſaid that even 2000 of them are ſometimes ſeen together. They are hunted on horſeback; the hide is applied to many uſeful purpoſes, and the fleſh is much eſteemed for food. The buffalo is not found tame in Sondân: the wild one is hunted by the Arabs, and uſed as food. The hippopotamus is killed for his ſkin, which, being very tough, makes excellent ſhields and whips; and alſo for his teeth, which are ſuperior to ivory. The horn of the rhinoceros is a valuable article of trade, and is carried to Egypt, where it is ſold at a high price, and uſed for ſabre hilts and various other purpoſes. The antelope and the oſtrich are very common. The civet cat is common here; and leopards, though common in a certain diſtrict, are not found near the ſeat of government. The Arabs hunt them, ſtrip off the ſkin, which they ſell, and often eat the fleſh; imagining that it generates courage and a warlike diſpoſition. The other quadrupeds are the jerboa or mus jàculus, the abelang or ſimia Æthiops, the porcupine or hiſtrix cieſtria, and the kandar, or ſimia cynamolgos. The birds are the oriental dotterel, Guinea fowl, Egyptian quail, white-headed vulture, green peroquet, common pigeon, red partridge, owls, though not common, and columba turtur, very common. The white-headed vulture is exceedingly ſtrong, and very long-lived. The fiſh in the river Ada conſiſt of nearly the ſame ſpecies with thoſe of the Nile in Upper Egypt: they are caught in wicker-baſkets, and uſed for food. The chameleon abounds in Dar-Fûr, and alſo the viverra ichneumon, and almoſt all the ſpecies of lizard are ſeen here. Of ſerpents, the coluber hayé of Egypt, the coluber vipera, and the anguis colubrina, were the only ſpecies ſeen by Mr. Browne. The Fûrians have not the art of charming them, like the Egyptians and Indians. The white ant, or termites, is very numerous, and exceedingly deſtructive; a bull's hide is no ſufficient defence againſt it. The common bee alſo abounds, but they have no hives; and the wild honey is commonly of a dark colour and unpleaſant taſte. The locuſt of Arabia, gryllus, is very common, and is frequently roaſted and eaten, particularly by the ſlaves.

Of metals, the number found in the diſtrict viſited by Mr. Browne is ſmall; but to the ſouth and weſt, thoſe of almoſt all deſcriptions are to be met with. Copper of the fineſt quality, and iron, are very common either in Fûr or its vicinity. Silver, lead, and tin, are brought hither from Egypt. Of gold, in the countries to the eaſt and weſt, the ſupply is abundant. Alabaſter and various kinds of marble

exiſt

exiſt within the limits of Fûr. The rocks chiefly conſiſt of granite. Of ſtone adapted to building, or convertible into lime, there is either none, or the quantity muſt be extremely ſmall. Foſſile ſalt is common within a certain diſtrict; and there is a ſufficient ſupply of nitre, but it is applied to no uſe. A quantity of ſulphur is brought by the Arabs from the ſouth and weſt. The characteriſtic marks of thoſe trees which moſt abound in Dar-Fûr are their ſharp thorns, and the ſolid unperiſhable quality of their ſubſtance. Of the vegetables, which are very various, we can only ſelect the following, *viz.* the ſolanum ſanctum, or night-ſhade, uſed for food, two kinds of beans, which are ſtrung and uſed as ornaments by the women, the common onion, garlick, water-melon, cucumber, the gourd uſed for food when freſh, and ſerving for drinking veſſels and other purpoſes, the colocynthis, very common, the uſhar, a plant ſo common as to cover whole plains, and uſed under mats and goods to guard them from the depredations of the white ant; hemp much cultivated, rice, cayenne-pepper, ſeſamum uſed for food, and by the great for fattening their horſes, Mahreik and dohn, the holcus dochna of Forſkal, which are the baſis of their proviſion, particularly the latter, and tobacco, which ſeems to be of native growth.

The government is a kind of deſpotic monarchy, ſimilar to that of other countries, in which the Mahometan religion is profeſſed; the ſovereign of Dar-Fûr ſpeaks in public of the ſoil and its productions as his perſonal property, and of the people as little elſe than his ſlaves. The only perſons to whom he pays any great attention are his ſoldiers. His power in the provinces is delegated to officers, who poſſeſs an authority equally arbitrary. On the death of the monarch, the title deſcends of right to the eldeſt of his ſons; though the ſucceſſion is often diverted under various pretences.

The rainy ſeaſon in Dar-Fûr is called "Harif;" and this is of great importance to the country. The changes of the wind are not periodical, but inſtantaneous. With a ſoutherly wind the greateſt heat prevails, and with a ſouth-eaſt wind the greateſt quantity of rain falls. The breeze from the north and north-weſt is moſt refreſhing; and the hot and oppreſſive winds, which fill the air with thick duſt, blow conſtantly from the ſouth. The harveſt is conducted in a very ſimple manner. The women and ſlaves of the proprietor are employed to break off the ears with their hands, leaving the ſtraw ſtanding, which is afterwards applied to buildings and various other uſeful purpoſes. They are then carried away in baſkets. When thraſhed, which is awkwardly and incompletely performed, they expoſe the grain to the ſun till it becomes quite dry; and then dig a hole in the earth, the bottom and ſides of which are covered with chaff to exclude the vermin. This cavity is filled with grain, which is covered firſt with chaff and then with earth. When it is wanted for food, they grind it, and boil it in the form of polenta; and eat it either with freſh or ſour milk, or, more frequently, with a ſauce made of dried meat pounded in a mortar, and boiled with onions, &c. The Fûrians uſe little butter. As a ſubſtitute for bread, cakes of the ſame material are baked on a ſmooth ſubſtance prepared for the purpoſe, which are very thin and not unpalatable. Theſe are eaten with the above-mentioned ſauce, or with milk, or merely with water; but in whatever form the grain be uſed, the rich cauſe it to be fermented before it be reduced to flour, which gives it a very agreeable taſte. They alſo eat the dohn raw, moiſtened with water, without either grinding it or ſubjecting it to the operation of fire.

In the beginning of the wet ſeaſon, or "Harif," the king goes out with his meleks and the reſt of his train, not only to obſerve the ſowing of the ſeed, but to take part in the operation, by making ſeveral holes with his own hand. Whether this uſage be antecedent to the introduction of Mahometaniſm into the country, is not known; but as it is attended with no ſuperſtitious obſervance, it would rather ſeem to belong to that creed. In order to make ſome eſtimate of the population of the country, Mr. Browne directed his attention to the war levies. Hence he concludes, that the number of perſons within the empire cannot much exceed 200,000. In the whole country there are only eight or ten towns of great population. Among the people of Dar-Fûr the Arabs are very numerous; they lead a wandering kind of life in the frontiers, and breed camels, oxen, and horſes; and they are not in ſuch a ſtate of abſolute dependence as to contribute effectually to the ſtrength of the monarch in war, or to his ſupplies in peace. After the Arabs we may mention the Zeghawa, which once formed a diſtinct kingdom, whoſe chief went to the field wiah a thouſand horſemen from among his own ſubjects. The Zeghawa ſpeak a different dialect from the people of Fûr. We muſt then enumerate the people of Bêgo or Dageou, who are now ſubject to the crown of Fûr, but are a diſtinct tribe, which formerly ruled the country. Kordofân, which is now ſubject to Fûr, and a number of other ſmaller kingdoms, as Dar-Berti, &c. &c. Dar-Rugna, which has a king, who is, however, dependent, but more on Bergoo than on Fûr. What are the numbers of each it is not eaſy to aſcertain.

The buildings of the Fûrians are very plain and ſimple. A ſlight roof ſhelters them from the ſun and rain; the walls are built of clay, and the people of higher rank cover them with a kind of plaſter, and colour them red, white, or black. The apartments are of three kinds; one is called a "donga," which is a cube commonly formed in the proportion of 20 feet by 12. The four walls are covered with a flat roof, conſiſting of light beams laid horizontally from ſide to ſide; over this is ſpread a ſtratum of uſhar, or ſome other light wood, or coarſe mats; a quantity of dried horſe's or camel's dung is laid over this, and the whole is finiſhed with a ſtrong and ſmooth coating of clay. The roof has a ſlight obliquity, having ſpouts to carry off the water. The "donga" is provided with a door, conſiſting of a ſingle plank, hewn with the axe, as the plane and ſaw are unknown. It is ſecured by a padlock, and thus conſtitutes the repoſitory of all their property. The next apartment is called a "kournak," which is ſomewhat larger than the donga, having no door, and having no other roof but thatch, like our barns, compoſed of kaſſob, the ſtraw of the maize, and ſupported by light rafters. This is cooler in ſummer than the more cloſely covered buildings, and is appropriated to receiving company, and ſleeping. The women are commonly lodged, and dreſs their food in another apartment of the ſame kind as the laſt, but round, and from 15 to 20 feet in diameter, and this is called "ſukteia." A houſe in which there are two "dongas," two "kournaks," and two "ſukteias," is conſidered as a large and commodious one, adapted to the uſe of merchants of the firſt order. A "rukkuba" (ſhed) is frequently added; and this is merely a place ſheltered from the ſun, where a company ſit and converſe in the open air. The interior fence of the houſe is commonly a wall of clay; the exterior univerſally a thick hedge, conſiſting of dried branches of acacia and other thorny trees, which ſecures the cattle, and prevents the ſlaves from eſcaping.

The troops of Dar-Fûr are not famous for military ſkill, courage, or perſeverance. In their campaigns, therefore, they

they chiefly rely on the Arabs, who accompany them, and are more properly tributaries to the ſultan than his ſubjects. In their perſons the Fûrians are not remarkable for cleanlineſs, though obſerving as Mahometans all the ſuperſtitious formalities of their religion; their hair is rarely combed, or their bodies completely waſhed. The hair of the pubes and axillæ they uſually exterminate; but they know not the uſe of ſoap, ſo that with them the poliſhing of the ſkin with unguents ſupplies the want of perfect ablutions, and real purity. An inveterate animoſity ſubſiſts between the natives of Fûr, and thoſe of Kordofân, which ſeems to be owing to their relative poſitions, Kordofân lying in the way between Dar-Fûr and Sennaar; and this is the moſt practicable communication between the former and Mecca. Nothing reſembling current coin is known in Soudân, unleſs it be ſmall tin rings, the value of which is arbitrary; gold, not being found within the limits of Fûr, is ſeldom ſeen in the market. The articles chiefly current are all ſuch as belong to their dreſs, ſuch as cotton cloths, beads, amber, kohhel, rhéa, ; and on the other hand oxen, camels, and ſlaves.

The diſpoſition of the people of Fûr appears to be more cheerful than that of the Egyptians. Prone to intoxication, but unprovided with materials or ingenuity to prepare any other fermented liquor beſides "buza," with this alone their exceſſes are committed; and this liquor they freely uſe, though it is prohibited by an ordinance of the ſultan, under pain of death. This buza has a diuretic and diaphoretic tendency, which precludes danger from their exceſs in the uſe of it. In this country dancing is a favourite and common amuſement, both among the men and women; and even the ſlaves dance in fetters to the muſic of a little drum. The vices of thieving, lying, and cheating in bargains, are very prevalent; and ſo much are they addicted to fraud, that in buying and ſelling the parent glories in deceiving the ſon, and the ſon the parent. Of the privilege of polygamy, allowed by their religion, they freely avail themſelves, ſo that the Fûrians take both free women and ſlaves without limitation. The ſultan has more than 100 free women, and many of the meleks have from 20 to 30. The females here are not under ſuch reſtraints as they are in many other countries. None attempt to conceal their faces but the wives of the great, who do it from an affectation of delicacy, more than from real modeſty; thoſe of the middle and inferior rank are always contented with the ſlight covering of a cotton cloth wrapped round their waiſt, and, occaſionally, another of the ſame form, materials, and ſize, artleſsly thrown over the ſhoulders. They never eat with the men. Some of the moſt labourious domeſtic offices in this country are performed by the women; they not only prepare the ſoil and ſow the corn, but aſſiſt in gathering it. They alſo grind it, and convert it into bread. Their clay buildings are chiefly conſtructed by the women. Their labour, however, is accompanied with a conſiderable degree of authority and influence in domeſtic concerns.

Previouſly to the eſtabliſhment of Iſlamiſm, about a century and a half ago, and kingſhip, the people of Fûr ſeem to have formed wandering tribes, in which ſtate many of the neighbouring nations remain to this day. In their perſons they differ from the negroes of the coaſt of Guinea; their hair is generally ſhort and woolly; and their complexion is for the moſt part perfectly black. But the Arabs, who live among them, and intermarry with them, retain their diſtinction of feature, colour, and language. In moſt of the towns, except Cobbé, which is the chief reſidence of foreign merchants, and even at court, the vernacular idiom is in more frequent uſe than the Arabic, and their judicial proceedings are conducted in both languages. Next to the officers of government, the "faqui," or learned man, *i. e.* the prieſt, holds the higheſt rank. Their learning, however, ſolely conſiſts in the knowledge of the Koran. The revenues of Dar-Fûr ariſe from ſeveral ſources. On all merchandize imported the king has a duty amounting in ſome inſtances to near a tenth. When the merchants of Egypt leave Dar-Fûr on their return to their own country, another tax is demanded on the ſlaves exported. All forfeitures for miſdemeanours are due to the king, and theſe amount to a conſiderable value. Every judicial proceeding is brought before the king, attended with a preſent proportioned to the rank and property of the perſons concerned. The king is entitled to a tenth of all the merchandize, and eſpecially ſlaves, brought from all quarters, and in caſe of an expedition to procure ſlaves by force, this tenth becomes a fifth. At a particular time of the year, when a ceremony called "leathering the kettle-drum," takes place, all the principal people muſt attend with preſents, which furniſh a very conſiderable addition to the royal revenue. Preſents are cuſtomary on many other occaſions. But one of the principal ſources of revenue is the tribute of the Arabs, who breed oxen, horſes, camels, and ſheep. Moreover, every village is obliged to pay annually a certain ſum in corn, dohn, which is collected by the king's ſlaves. The king is alſo the chief merchant in the country; and he diſpatches, with every caravan to Egypt, a great quantity of his own merchandize, and employs his ſlaves and dependants to trade for him.

The people of Fûr are repreſented as uſing many ſuperſtitious ceremonies at the "leathering of the kettle-drum;" among others, it is ſaid, they put to death in the form of a ſacrifice a young boy and girl. Even to this day many idols are worſhipped by the women of the ſultan's haram; and the mountaineers offer a kind of ſacrifice to the deity of the mountains, when they are in want of rain. For further particulars we muſt refer to Mr. Browne's ample and intereſting account of Dar-Fûr, and the adjacent countries, in his "Travels in Africa, &c. from the year 1792 to 1798."

DARGAN, a town of Aſia, in the country of Charaſm, ſituated on the Gihon.

DARGASIN, a town of Perſia, in the province of Irac-Agemi; 48 miles N.E. of Amadan.

DARGASP, a town of Perſia, in the province of Segiſtan, ſeated on the river Hinmand.

DARGEL, a river of the county of Wicklow, in Ireland, which falls into the Iriſh ſea at Bray. In its courſe it paſſes through ſome very romantic glens, one of which, in the demeſne of lord viſcount Powerſcourt, is peculiarly ſtriking, and is much frequented. In the neighbourhood is a very fine fall of water, which is generally viſited at the ſame time. An excurſion to the Dargel and water-fall never fails to delight the lovers of pictureſque ſcenery, and deſcriptions of them may be found in moſt of the travels through Ireland.

DARGIDUS, in *Ancient Geography*, a river of Aſia, in Bactriana; which had its ſource in mount Paropamiſus, and after a northern courſe diſcharged itſelf into the Oxus.

DARGIES, in *Geography*, a ſmall town of France, in the department of the Somme; 6 miles S. of Poix.

DARGOMANES, in *Ancient Geography*, a river of Aſia, in Bactriana, which ran into the Oxus; ſome have ſuppoſed that it is the Morga or Marou of modern times.

DARGUN, or DRAGUN, in *Geography*, a ſmall town of Germany, in the duchy of Mecklenberg Schwerin, in the diſtrict of Roſtock, with an ancient ducal palace, which was originally a convent of Benedictine monks, founded in 1149.

DARIC, in *Antiquity*, a famous piece of gold, firſt coined, as ſome have ſaid, by Darius the Mede, about 538 years

B. C.; probably during his ſtay at Babylon, out of the vaſt quantity of gold which had been accumulated in the treaſury: but as others ſay, by Darius ſon of Hyſtaſpes, who began his reign 521 years B. C. It is much queſtioned, however, whether the Athenians ever ſtruck any gold coin, while they were a free and flouriſhing people. The hiſtoriographers, indeed, tell us, the χρυσοῦς Ἀττικός was equal to the daric, and ſpeak of gold mines at Laurium; but no ancient writer mentions ſuch a coin, and all agree that the mines at Laurium were ſilver. That they had no gold, even at the beginning of the Peloponneſian war, appears from the account given by Thucydides, (lib. xi. c. 13.) of the drachma, then in the Acropolis, which conſiſted of ſilver in coin, and gold and ſilver bullion: but he would certainly have mentioned gold in coin, if there had been any. From Babylon the Perſian daric was diſperſed over the Eaſt, and alſo into Greece; ſo that this coin, which was alſo called ſtater, was the gold coin beſt known in Athens in ancient times. The ſize and weight of theſe darics have not been accurately aſcertained. Joſephus, cited by Arbuthnot, ſays they were equal to the didrachm in weight, and worth 50 Greek drachmæ. But many authors, particularly Xenophon, inform us, they were didrachms, and worth 20 ſilver drachmas. According to Dr. Bernard, the daric weighed two grains more than one of our guineas; but as it was very fine, and contained little alloy, it may be reckoned worth about twenty-five ſhillings of our money. Plutarch informs us, that the darics were ſtamped on one ſide with an archer clothed in a long robe, and crowned with a ſpiked crown, holding a bow in his left hand, and an arrow in his right; and on the other ſide with the effigies of Darius. All the other pieces of gold of the ſame weight and value, that were coined by the ſucceeding kings both of the Perſian and Macedonian race, were called darics, from Darius, in whoſe reign this coin commenced. Of theſe there were whole darics and half darics: and they are called in thoſe parts of Scripture written after the Babyloniſh captivity, adarkonim; and by the Talmudiſts, darkonoth. Greaves ſays that the daric is ſtill found in Perſia; but it is certainly very ſcarce, and perhaps of doubtful antiquity. Theſe were moſtly melted down by Alexander the Great upon his conqueſt of Perſia. There is one of them in lord Pembroke's cabinet, which weighs 129 grains, and ſhews them to have been didrachms on the Eubœic or Attic ſtandard. Suidas in Δαρεικός. Bernard de Ponder, &c. p. 171. Prideaux's Conn. vol. i. p. 182, &c. Phil. Tranſ. vol. lxi. part 2. art. 48. Pinkerton's Eſſ. on Medals, vol. i. ſect. 17.

DARIAUSA, in *Ancient Geography*, a town of Aſia, in the interior of Media.

DARIDNA, a town of Paphlagonia. Steph. Byz.

DARIEN, in *Geography*, a poſt-town of America, in M'Intoſh county and ſtate of Georgia, near the heights of which the north channel of Alatamaha river flows, about 20 miles above Sapalo iſland, and 10 below fort Barrington: 47 miles S.S.W. of Savannah. N. lat. 31° 23′. W. long. 80° 14′.

DARIEN, *Gulf of*, the mouth of a large river, or an arm of the ſea, in a province of South America, of the ſame name, running up into the land for a conſiderable diſtance, and opening into the Caribbæan ſea, or Spaniſh main; about N. lat. 8°, and W. long. 76° 30′. In this gulph are three iſlands of conſiderable ſize, *viz.* Golden iſland; another, the largeſt of the three, and the iſland of Pines, beſides ſome ſmaller ones.

DARIEN, *Iſthmus of*, a province of the vice-royalty of New Granada, in South America; and the northern part of Terra Firma; extending on both ſides of the gulf of the ſame name; and from the proximity of the city of Panama and a conſiderable coaſt on that bay, reaching as far as the diſtrict of Zinu, with a length of ſhore on the Caribbæan ſea. It is bounded on the north by the Caribbæan ſea, or Spaniſh main, on the eaſt by the province of Carthagena, on the ſouth by the bay of Panama, Choco, and the country of Popayan, and on the weſt by Veragua and part of the Pacific ocean. It is ſometimes called Terra Firma Proper, to denote that, however narrow this iſthmus, in the part of it which adjoins to or includes Panama, ſometimes called the Iſthmus of Panama, it was firm land, or belonged to the continent: or rather, becauſe the name was applied indifferently to this and the adjacent province of Veragua in North America, aſſigned as a dukedom to Colon or Columbus, and diſcovered by that great navigator to be certainly continental, when he explored the harbour of Portobello, on his fourth voyage in 1502. This province, which is the largeſt of thoſe in Terra Firma, is about 260 miles in length, and about 80 miles in medial breadth, forming a kind of bow or creſcent about the great bay of Panama, in the Pacific ocean, or South ſea. Its breadth is only about 37 miles from Portobello to Panama, the two chief towns of the province. This neck of land, which, as it were, binds together the continents of North and South America, is ſtrengthened by a chain of lofty mountains ſtretching through its whole length, and rendering it a ſolid barrier ſufficient to reſiſt the impulſe of the oppoſite oceans. The rocky mountains here evince the impracticability of a canal; but by aſcending to a higher latitude northwards, and joining the head of Nicaragua lake to a ſmall river, which runs into the Pacific ocean, a communication might be formed between the two ſeas; and by digging 30 miles through a level low country, a tedious navigation of 10,000 miles round cape Horn might be avoided. Such a junction might in a ſeries of years wear away the ſolid parts of the iſthmus, and form a broad ſtrait between the oceans; in which caſe the gulf ſtream, being turned into a different channel, might ceaſe, and a voyage round the world be much expedited. Neither of theſe oceans fall in at once upon the ſhores, but are intercepted by a great many valuable iſlands, that lie ſcattered along the coaſt, both in the bay of Panama, and in the gulf of Darien. The mountains of Darien are covered with almoſt inacceſſible foreſts. From the tops of ſome of theſe the Spaniards firſt diſcovered the South, or Great Pacific ocean, in the year 1513, and called it the South ſea, becauſe they croſſed the iſthmus from the North ſea; though in reality the Pacific ocean lies weſt of the main land of America. Valleys in that moiſt climate, where it rains two-thirds of the year, are marſhy, and ſo frequently overflowed, that the inhabitants find it neceſſary, in many places, to build their houſes upon trees, in order to elevate them at ſome diſtance from the damp ſoil, and the odious reptiles generated in the putrid waters. Large rivers run down with an impetuous current from the high grounds. In a region thinly inhabited by wandering ſavages, ſingularly wild and ferocious, the hand of induſtry has done little or nothing to mitigate or correct theſe natural diſadvantages. Although ſome of the rivers which water this country are moderately large, yet few of them are navigable, on account of the bars and ſhoals at their mouths. On the N. coaſt the rivers are generally very ſmall, for as they moſtly riſe from the main ridge, which lies near the ſhore, their courſe is very ſhort. The river of Darien, indeed, is very large; but its depth at the entrance does not correſpond to the extent of its mouth, though farther in it is of ſufficient depth. But from thence to Chagre, through the whole length of this coaſt, the rivers are little better than brooks.

brooks. Some of the rivers of this province bring down gold duſt, and on the coaſt are valuable pearl fiſheries.

This province might be of great importance to the Spaniards; and, indeed, its ſituation on both in the North and South ſeas, the gold ſands of its rivers, the treaſures of Peru, brought hither and imported into Old Spain, have induced ſeveral adventurers to make attempts for framing advantageous ſettlements at Panama, Portobello, &c. But the country is extremely hot, and the low lands are inundated with continual rains; ſo that the country is ſingularly unhealthy. Portobello, though in many reſpects an advantageous ſituation, is nearly ruined: nor have the Spaniards, though ſufficiently diſpoſed to avail themſelves of advantages that preſented themſelves, been able to form any permanent eſtabliſhments either on the gulf of Darien on the Caribbæan Sea, or that of San Miguel in the Pacific. On the contrary, all the ſtations have been withdrawn, exeept a little fort, which protects the gold mine of Cana, on the frontiers of Choco; and the little garriſon, which comes from Panama, is changed every month. The only products were ſome cotton and tobacco. In 1786 the viceroy of New Granada ſent an expedition againſt the ſavages of Darien, but the Spaniſh troops could not bear the climate. The Indians are ſuppoſed to amount to 30,000 perſons, without chiefs, and acknowledging no authority, ſo that it is impoſſible even to form a laſting treaty.

About 10 years after Columbus had diſcovered the main land of America, the Spaniards ſeriouſly attempted to eſtabliſh a ſettlement in the country. In purſuance of theſe attempts, a feeble colony ſettled in the year 1510, at Santa Maria de Antigoa, on the gulf of Darien, under the command of Vaſco Vagnez de Balboa, who gained the confidence of his countrymen by his diſtinguiſhed courage and conduct. See BALBOA.

For an account of the expedition of the Scots to this province, ſee *Scotch Darien* COMPANY and CALEDONIA.

DARII, in *Logic*, a mode of ſyllogiſms in the firſt figure, wherein the major propoſition is an univerſal affirmative, and the minor and concluſion particular affirmatives. *E. gr.*

DA "They who ſpeak well of every body have many friends."
RI "Some ſpeak well of every one."
I "Therefore ſome have many friends."

DARION, in *Ancient Geography*, a town of Phrygia. Steph. Byz.

DARIOVIGUM, afterwards called *Veneti*, a town of Gaul, in the ſouthern part of Armorica. Cæſar ſays, that this town, which was ſituated on a point of land ſurrounded by the ſea, twice a day, was rich and powerful, and that it had the command of the ſea, and of the whole commerce of Armorica. He took it with difficulty, deſtroyed it, and ſold the inhabitants by public ſale. It was the capital of the *Veneti*.

DARISTANE, a town of Perſia, the inhabitants of which were called *Daritæ*.

DARITIS REGIO, a country of Media.

DARIUS I., in *Biography*, king of Perſia, was the ſon of Hyſtaſpes, a commander under Cyrus the Great; and by Cambyſes he was made governor of the province of Perſia. When Smerdis uſurped the throne, Darius aſſociated himſelf with ſix other perſons, in order that they might deſtroy the tyrant. They ſucceeded; he was killed by the hand of Darius. Afterwards they agreed that the ſeven ſhould repair to the city, and he whoſe horſe firſt neighed ſhould be proclaimed ſole ſovereign. Darius, it is thought, uſed ſome ſpecial means to obtain the crown, and he was accordingly raiſed to the empire of Perſia, B. C. 521. On his acceſſion he married the two daughters of Cyrus, and other wives: and divided the whole empire into twenty governments, and appointed a certain tribute to be paid by each, that of Perſia only excepted. Darius was guilty of ſome cruelties; but he is celebrated in hiſtory for the permiſſion which he gave to the Jews to reſume the rebuilding of their temple, which had been interrupted by the malicious inſinuations of the Samaritans.

In the early part of his reign the Babylonians revolted, nor was it in the power of Darius with all his force to take their city, to which he laid ſiege; at length Zopyrus, one of his principal officers, in zeal for his ſovereign cut off his ears and noſe, and pretending that it was a puniſhment inflicted upon him by the king, went over to the enemy, and obtained their confidence, which he employed to betray the gates of the city to the Perſian army. Darius exerciſed extreme cruelty on the conquered, but beſtowed on his officer Zopyrus the moſt magnificent rewards. Darius next engaged in an expedition againſt the Scythians: he marched with a vaſt army to the Thracian Boſphorus, which he croſſed by a bridge of boats, and after reducing Thrace, advanced to the Danube, which he croſſed, and entered Scythia, but he was obliged to return without gaining any material advantages. Darius is ſaid to have conquered India; but his triumphs did not extend, probably, far into the country. The ſucceſſes of this ſovereign were various; in ſome inſtances his ambition was completely checked, in others he was glad to withdraw his armies with great loſs. In an expedition againſt Greece the enterpriſe was committed to Mardonius, who marched through Thrace into Macedonia, which ſubmitted to his arms; but as he was proceeding ſouthward, his fleet was almoſt wholly ruined by a ſtorm, ſo that he was obliged to return ingloriouſly into Aſia. Darius did not, however, abandon his deſign: he ſent a powerful army, with orders to ſack the cities of Athens and Eretria, and to ſend him all the ſurviving inhabitants in fetters. The Perſians took the iſle of Naxus, and city of Eretria; but they were defeated at Marathon by the Athenians and Plateans, commanded by the celebrated Miltiades. Their fleet was alſo completely unſucceſsful in an attempt to ſurpriſe Athens. He now reſolved to go into Greece himſelf, and iſſued orders to all his ſubjects in the ſeveral provinces of the empire to accompany him in his expedition; but after he had ſpent three years in making the requiſite preparations, a new war was occaſioned by the revolt of Egypt. He then determined to ſend part of his forces againſt the Egyptians, while he marched with the remainder into Greece. When every thing was ready, and Xerxes his ſon declared heir-apparent to the crown, Darius fell ſick and died, in the thirty-ſixth year of his reign. This happened in the year B. C. 485. This ſovereign was endowed with many good qualities: his wiſdom, juſtice, and clemency are warmly commended by the ancients; and when he is compared with the generality of eaſtern deſpots, he may be entitled to the praiſe of juſtice and humanity.

DARIUS II. ſurnamed Ochus, and alſo Nothus, was one of the natural ſons of Artaxerxes Longimanus. He aſcended the Perſian throne in the year 423 B. C. His hiſtory as a ſovereign is but a deſcription of ſucceſſive revolts, terminating in the defeat and death of thoſe who excited them. He died in the 20th year of his reign, and was ſucceeded by his ſon Arſaces, who aſſumed the name of Artaxerxes, and received the appellation of Mnemon from the Greeks, on account of his extraordinary memory. It is related of Mnemon, that while attending upon his father in his laſt hours, he aſked how he could beſt perform the duties of government, to which Darius replied, that he had himſelf

conſtantly acted, to the beſt of his knowledge, in obedience to the dictates of juſtice and religion.

Darius III. named Codomannus, was placed on the throne by Bagoas the eunuch, who had murdered Arſes, the youngeſt ſon of Artaxerxes Ochus. Codomannus did not, however, fully anſwer the expectations of Bagoas, and he reſolved to deſtroy him alſo by poiſon; but the plot was diſcovered, and the perfidious eunuch was obliged to drink the fatal cup himſelf. The whole of this prince's reign is that of a ſtruggle againſt the Macedonian invaſion, the events of which will be found in another part of our work. See Macedonia and Persia. Darius did not take the command of his army in perſon till Alexander advanced into Cilicia. He then proceeded to meet him in all the pomp of royalty; but with a force ill adapted to contend with ſuch an enemy. He reſolved nevertheleſs to hazard a battle, contrary to the advice and opinion of his Greek allies. The battle at Iſſus was fought, and Darius took the command, but fled with ſuch precipitation, that he left behind him his bow, ſhield, and mantle. His camp was plundered, and his mother, wife, and children fell into the power of the conqueror. In vain after this did Darius ſupplicate for an accommodation: Alexander went on in the career of victory, and in a ſecond pitched battle, at Gaugamela, Darius again fought, and again diſgracefully fled. He now loſt Babylon, Suſa, Perſepolis, and all his treaſures, and ſought for perſonal ſafety at Ecbatana; but his misfortunes had alienated the minds of his ſubjects, and he was ſeized by Beſſus, governor of Bactria, who aſſumed the royal authority in his ſtead. Alexander cloſely purſued the uſurper and his captive beyond the Caſpian Straits. Here Darius determined to remain; but his reſolution coſt him his life: he was wounded by his own ſubjects, and left weltering in his blood. Of Polyſtratus, a Macedonian, he beſought a little water, which being brought to him, he deſired that his acknowledgments and thanks might be conveyed to Alexander for his kindneſs and attention to his family, with an earneſt exhortation that he would avenge his death on the traitors. Darius immediately breathed his laſt in the arms of Polyſtratus. This was in the 330th year B. C. being the 50th of the monarch's age, and the 6th of his reign. When his enemy Alexander beheld his rival dead, he is ſaid to have wept over him, to have covered the body with his own cloak, and ſent it to be embalmed, and interred with the remains of the Perſian monarchs. Univerſal Hiſtory.

Dark-Chamber. See Camera-*Obſcura*.

Dark-*Rays*, in *Philoſophy*, are certain emanations from the ſun, which have been recently diſcovered. They are not perceptible to our eyes, but they are manifeſted by their effects. Dr. Herſchel, and Mr. Ritter, are the diſcoverers of theſe emanations. The former of thoſe gentlemen obſerved, that when the rays of the ſun are refracted by a glaſs priſm, and form the coloured ſpectrum upon any ſurface, a thermometer placed beyond the ſpectrum is elevated by the heat of certain rays or emanations, which are by no means viſible; ſo that in fact, if the expreſſion be allowable, there is an inviſible ſpectrum of *calorific* rays, independent of the viſible ſpectrum of coloured rays, formed by the priſmatic refraction of ſolar light. Dr. Herſchel traced the extent of the former, and endeavoured to aſcertain the various intenſities of heat in different parts of it. But a more particular account of theſe inviſible calorific rays will be found under the articles, Solar *heat*, and Rays *of heat*.

Mr. Ritter, on the continent, and, ſoon after, Dr. Wollaſton in England, unknown to each other, diſcovered that the luminous ſolar rays are accompanied with certain other inviſible rays or emanations, which are only cognizable by their chemical effects upon certain ſubſtances, ſuch as muriate and nitrate of ſilver. Theſe rays are more refrangible than the violet rays of the coloured ſpectrum. Dr. T. Young, ſpeaking of theſe inviſible rays of Ritter, in a paper which is to be found in the Phil. Tranſ. for the year 1803, ſays, "I was deſirous of examining the effect of their reflection, from a thin plate of air, capable of producing the well known rings of colours. For this purpoſe I formed an image of the rings, by means of the ſolar microſcope, with the apparatus which I have deſcribed in the journals of the Royal Inſtitution; and I threw this image on paper dipped in a ſolution of nitrate of ſilver, placed at the diſtance of about nine inches from the microſcope. In the courſe of an hour, portions of three dark rings were very diſtinctly viſible, much ſmaller than the brighteſt rings of the coloured, and coinciding very nearly, in their dimenſions, with the rings of violet light that appeared upon the interpoſition of violet glaſs. I thought the dark rings were a little ſmaller than the violet rings, but the difference was not ſufficiently great to be accurately aſcertained; it might be as much as $\frac{1}{30}$ or $\frac{1}{40}$ of the diameters, but not greater. It is the leſs ſurpriſing that the difference ſhould be ſo ſmall, as the dimenſions of the coloured rings do not by any means vary at the violet end of the ſpectrum, ſo rapidly as at the red end."

It appears then, that the ſolar light conſiſts of three different emanations, or of three different kinds of rays; *viz.* the viſible coloured rays, the inviſible calorific rays, and the inviſible rays which are only diſcernible by their chemical effects upon certain ſubſtances. All theſe emanations are intermixed with each other in the direct rays of the ſun; but, being differently refrangible, they are ſeparated from each other by the glaſs priſm, and their preſence is manifeſted by their peculiar properties.

Dark-*Tent*, a portable camera obſcura, made not unlike a deſk, and fitted with optic glaſſes, to take proſpects of landſcapes, buildings, fortifications, &c. See Camera *Obſcura*.

DARKEHMEN, in *Geography*, a ſmall town of Pruſſia, in that part of Eaſtern Pruſſia which is called Lithuanian Samland, in the diſtrict of Inſterburg, remarkable for its woollen cloth manufactures, and for a colony of Saltzburghers, who ſettled in the year 1732.

DARKNESS means the abſence or the want of light. In common language we conſider ourſelves as being in darkneſs, whenever objects that are pretty near to us, cannot be diſtinguiſhed from each other; but perfect darkneſs does not eaſily occur; and it is owing to this that ſeveral animals can ſee in what we call darkneſs; *viz.* the eyes of thoſe animals are ſo formed as to be able to ſee with very little light. But it appears from the experiments of M. le Cat and others, that no animal can ſee in perfect darkneſs where no light is emitted, even from any phoſphoreſcent body; and ſuch phoſphoreſcence may ſometimes proceed even from the animal itſelf.

The inquiries concerning the nature of darkneſs are ſo intimately connected with thoſe of light, (for the one is the want of the other,) as not to demand any particular examination in this place. The grand queſtion is, whether light is an emanation of matter from the luminous body, or is the propagation of a certain movement through a peculiar ſubſtance conſtantly diſperſed throughout the univerſe. Whence it follows, that darkneſs either is a total privation of light, or a ſtate of quieſcence in that matter which, when put in motion, produces the phenomena of light. The preſent ſtate of philoſophical knowledge ſeems to render it more than probable, that light is a real ſubſtance thrown out in every direction

rection from the luminous bodies; this queſtion, however, will be particularly examined under the article LIGHT.

DARKSVILLE, in *Geography*, a town of America, in Maryland, containing 132 inhabitants.

DARLING ISLAND, is the largeſt of two iſlands at the entrance of lake Simcoe, in Upper Canada.

DARLINGTON, a market and borough-town in the county of Durham, England, is ſituated on the ſide of a hill, which ſlopes to the river Skerne, over which is a bridge of four arches. The name is ſuppoſed to be derived from *Der* or *Dar*, an ancient appellation of the river, *Inge*, the Saxon term for a meadow, and *ton*, a town or village. It is a place of remote antiquity. In the time of the Saxon king Ethelred, a nobleman named Stere, the ſon of Wulf, obtained permiſſion of the king, that Darlington, with its appendages, ſhould be reſtored to St. Cuthbert. To which the king, the archbiſhop of York, and Aldwine, biſhop of Durham, became witneſſes. And in the ſurvey, contained in "the Balden Buke," Darlington is particularly noticed. It is a large populous trading town, and borough by preſcription; conſiſting of ſeveral well built ſtreets, iſſuing from a central ſquare; and makes a clean and reſpectable appearance. Amongſt its buildings, the greateſt ornament is the church, which ſtands at the ſouth-weſt angle of the market place. It is ſaid to have been erected by biſhop Hugh Pudſey, about the year 1160, who alſo built a manſion-houſe near it, and inſtituted a college for a dean, and three ſecular canons. The church is a ſpacious ſtructure in the form of a croſs, with a tower crowned with a ſpire, which riſes to the height of one-hundred and eighty-feet. The tower ſprings from uniform arches in the centre, ſupported by cluſtered columns; but the arches of the nave and aſles are irregular in ſhape and ſize. The weſt door is highly finiſhed with arches, having alternate cylindric and octagonal pilaſters. In this church were four chantries amply endowed. The endowment of one, called Marſhal's chantry, was, in the time of Elizabeth, granted by the crown for the foundation of a free grammar-ſchool. The charter was granted 15th of June 1567, and a portrait of the royal founder was placed in the ſchool by the late George Allan, eſq. F.S.A.; as a memorial of his gratitude in having received his early education there. The epiſcopal palace, being in a decayed condition, is now leaſed for the purpoſe of a workhouſe. Darlington is conveniently ſituated near a river, and has a market well ſupplied, and proviſions cheap. Here is a very flouriſhing manufactory of worſted ſtuffs, ſuch as morreens, tammies, &c.; another of linens of different deſcriptions, particularly diapers, huckabacks, and checks. The manufacture of cotton has lately been introduced, under the direction of Mr. John Murrell, and promiſes to add to the population and reſources of the place. The abundance of water gives facility to the means of manufacturing, by the opportunity it affords of erecting machinery. Here is a mill for ſpinning wool, another for ſpinning hemp; and here was erected the firſt mill for grinding optical glaſſes in the kingdom. This was an invention of the late ingenious John Kindrew, a native of this place. Here is a ſociety for the improvement of agriculture; and an act was obtained about the year 1767 for cutting a navigable canal from Stocton, by Darlington, to Wurſton; but owing to a powerful oppoſition, it was never put into execution. According to the returns under a late act, Darlington contained 945 houſes, and 4670 inhabitants. Its market for wool, corn, cattle, and other proviſions, is on Mondays; and it has four annual fairs. The town ſends two members to parliament; and the living is a perpetual curacy. At Oxenhall, about three miles from Darlington, are ſome deep cavities, vulgarly called *Hell-Kettles*. Of their origin the Chronicles of Tinemouth priory give this account: "A. D. 1179, upon Chriſtmas-day at Oxenhall, in the outſkirts of Darlington, in the biſhopric of Durham, the earth raiſed itſelf up to a great height, in the manner of a lofty tower, and remained all that day until the evening, as it were fixed and immoveable, when it ſunk down with ſuch a horrid noiſe, that it terrified all the vicinity, when the earth abſorbed it, and there formed a deep pit." The diameter of the largeſt is not leſs than a hundred feet, and of the leaſt ſeventy-five, whilſt the depth is from ſix to nineteen feet; they have been conſidered by ſome to be ſhafts of neglected coal mines; by others, places where marle has been dug; but with more probability by the authors of the "Beauties of England and Wales," ſalt pits; and the name derived from the Britiſh word *hal*, an alkali, whence *halen*, ſalt; and *kiddle* or *kidle*, a dam, *i. e.* Hal-Kiddles. The riſing of the earth above ſtated may have been occaſioned from ſome exploſion of inflammable ſubſtances beneath the ſtrata. In 1805 was diſcovered a ſulphureous ſpring in the vicinity, of ſtrong medical powers; and it is now much frequented by perſons labouring under ſcorbutic and other complaints. Hutchinſon's Hiſtory of Durham, 3 vols. 4to.

DARLINGTON, a diſtrict of South Carolina, bounded S. and S.W. by Lynche's creek; about 35 miles long, and 21 broad.

DARLINGTON, a townſhip of America, in the county of Durham, Upper Canada, lying to the weſt of Clarke, and fronting lake Ontario.

DARMADIJERA, a town of Aſia, in Thibet; 3 leagues N. of Sarangpour.

DARMSTADT, a handſome town of Germany, and capital of the grand duchy of Heſſe Darmſtadt, one of the members of the confederation of the Rhine, and the ordinary reſidence of the grand duke. It is ſituated on the river of the ſame name; 18 miles S. of Frankfort on the Mayn, 21 S.E. of Mayntz, 24 N.E. of Worms, and 36 N.W. of Heidelberg. N. lat. 49° 51'. The palace is a very ſtately building, and there is a houſe built on purpoſe for military evolutions, ſufficiently capacious to admit 1500 men to perform their manual exerciſe, and accommodated with ſixteen ſtoves. See HESSE DARMSTADT.

DARNALL, a river of Wales, which runs into the Wye; 3 miles N.W. of Rhayadr Gowy.

DARNEL, in *Botany*. See LOLIUM.

DARNEL, in *Agriculture*, the name of a troubleſome weed, which is frequently met with among wheat, rye, and other crops. See LOLIUM *perenne*.

DARNEL, *Annual*, a name applied ſometimes to white darnel (*lolium arvenſe*), and what, in the ſouthern diſtricts, is often improperly termed crup. It has much ſimilarity to the red darnel, and is often miſtaken for ray, or rye-graſs, though the ſpike is much longer and paler. It is likewiſe annual, while the ray-graſs has an abiding root. The ſeeds of this troubleſome weed ripen at the ſame time with the grain, and are very injurious to wheat crops. They ſhould be carefully prevented from being ſown with the ſeed.

DARNENSIS, in *Ancient Geography*, an epiſcopal town of Africa, in Libya.

DARNETAL, in *Geography*, a ſmall town of France, in the department of the Lower Seine, not far from Rouen, remarkable for its excellent cotton manufacture, particularly of red and white printed, and of handkerchiefs of different ſizes.

DARNEY, a ſmall town of France, in the department of the Voſges, chief place of a canton, in the diſtrict of Mirecourt. It has 1033 inhabitants: but the canton contains a population of 9643 individuals, in 19 communes,

upon

upon a territorial extent of 265 kiliometres. Darney lies 24 miles W. of Remiremont.

DARNI, in *Ancient Geography*, a people of Irelānd, placed by Ptolemy N. of the Voluntii.

DARNIGHEIM. in *Geography*, a town of Germany, in the circle of the Upper Rhine, and county of Hanau-Munzenburg; 3 miles W. of Hanau.

DARNIS, in *Ancient Geography*, a town of the Cyrenaica, a little ſouth of the promontory of Drepanum.

DAROACANA, a town of Aſia, in the country of Paropumiſus ſituated between the chains of Caucaſus.

DAROCA, in *Geography*, a ſmall, tolerably built, walled town of Spain, in the province of Arragon, on the river Xiloca, ſituated in a ravin between two hills, S.S.W. of Saragoſſa. Its fortifications are decayed. To the weſt are mountains reckoned among the higheſt in Spain; and to the north-eaſt, the country is barren; but the environs of the town are fertile. It contains many religious houſes, and about 2860 inhabitants.

DAROMA, in *Ancient Geography*, a name given by Euſebius and Jerom to a canton of Paleſtine, extending from the north to the ſouth, from the town of Eleutheropolis, about 20 miles on the ſide of Arabia Petræa, and from eaſt to weſt from the lake Aiphaltites to Berſabea or Beer-ſheba.

DARORE, in *Geography*, a town of Hindooſtan, in the country of Dowlatabad; 95 miles N.W. of Beder.

DARQUE, in *Rural Economy*, a term ſignifying the quantity of peats one man can caſt, and two wheel in the courſe of a day.

DARRÆ, in *Ancient Geography*, a people of Arabia Felix. Ptolemy.

DARREIN, in *Law*, a corruption of the French dernier, laſt, and uſed in the like ſenſe: as darrein continuance, (ſee CONTINUANCE); darrein preſentment (ſee ASSISA *darrein preſentment*.)

DARRO, in *Geography*, a river of Spain, which runs through the city of Grenada, and joins the Xenil, a little below it.

DARRYFIELD, a town of America, in the ſtate of New Hampſhire; 15 miles S. of Concord.

DARSA, in *Ancient Geography*, a town of Piſidia, ſituated, according to Livy, near Cormaſa, N.W., near the mountains inhabited by the Solymi.

DARSINI, in the *Materia Medica of the Ancients*, a name given by ſome to cinnamon. It is generally uſed by Avicenna, Serapion, and the reſt of the Arabian phyſicians.

DARSIS, in *Medical Writers*, is uſed for an excoriation of the ſkin. Blancard.

DART, in *Aſtronomy* and *Geometry*. See SAGITTA.

DART, in *Geography*, a river of Devonſhire, in England, is the principal of ſeveral ſtreams which take their riſe in the extenſive wild, called Dart-moor. Like the ancient Tigris, its name is derived from one of its moſt diſtinguiſhing features, the rapidity of its courſe. This characteriſtic it long retains, after it has left the ſource at Gedleigh, as it deſcends into the plain to the weſt of Aſhburton; where it glides, in placid beauty, by the caſtle and church of Totneſs. It is navigable for ſmall veſſels from its mouth to about one mile above this town. A little below, receiving the tide, it rolls in majeſty between lofty hills, winding its ſtream at the feet of their rocky baſes; and paſſing the town and caſtle of Dartmouth, empties itſelf into the ſeas in the road of Torbay.

DART, in a *Military Senſe*, means a ſmall ſpear, or javelin, much in uſe among the ancients, and yet ſeen among many of the more barbarous nations; eſpecially where the uſe of gunpowder is little known. The Caffrees of South Africa are extremely expert in throwing the dart, called by them *Aſſagai*, and on many occaſions have diſplayed ſuch accuracy in this particular, as has ſurpriſed our moſt adroit rifle-men. The dart in uſe among the ancients was of two kinds; *viz.* ſpear-headed, that is, without barbs; or bearded, like the generality of arrows. The former were often attached to a long cord, which enabled the thrower to recover his weapon, where it miſſed the aim, or when it could be withdrawn from a fleſh-wound. Moſt darts have iron heads; but the Americans, particularly in the leſs frequented tracts of that immenſe continent, as well as the inhabitants of ſome parts of Africa, uſe only a hard wooden ſtaff, ſharpened at the point, and a little chared by means of fire; others uſe fiſh-bones, flints, ſea-ſhells, &c. in their darts as well as for their arrowe. We find the dart to be every where very ſimple, and ordinarily from three to five feet in length. During the American war, the regular troops, on either ſide, uſed to be greatly annoyed by theſe miſſiles; which the Indian allies threw during the night at the out-centinels and videttes. Though darts are not ſupplied with wings or feathers, as arrows uſually are, they fly with great force; and, by that vibratory motion, peculiar to this claſs of weapons, make very extenſive wounds, often to a great depth, and attended with uncommon inflammation.

DARTFORD, in *Geography*, is a market town in the hundred of Axton and lathe of Sutton, in the county of Kent, England. The name is derived from the river Darent, on which it is ſituated. The manor was anciently a demeſne of the Saxon king; and, at the time of the Norman ſurvey, belonged to the conqueror. Iſabella, ſiſter to king Henry III., was here married by proxy to the emperor Frederic, in the year 1235; and Edward III., in 1331, held a tournament at Dartford. The moſt remarkable event in hiſtory, reſpecting this place, was the inſurrection under Wat Tyler, in the fifth year of king Richard II.; owing to the inſolence of a tax-gatherer, on which occaſion the people of this town were incited to riſe, to revenge the affront. Rapin erroneouſly ſtates the inſurrection to have begun at Deptford. Edward III. founded a nunnery at Dartford in the year 1355, and placed it under the government of four preachers. Its annual revenues at the diſſolution, according to Dugdale, amounted to 380*l.* 9*s.* 0$\frac{1}{2}$*d.* Henry VIII. converted it into a royal reſidence. It is called the place-houſe, and a large embattled gate-way of brick is yet remaining. The church ſtands near the river, and is a ſpacious edifice, conſiſting of a nave, chancel, and aiſles, with an embattled tower at the weſt end. On the north ſide of the chancel is a mural monument, commemorative of ſir John Spielman, a German, who, in the reign of Elizabeth, firſt introduced the manufacture of paper into this kingdom.

A branch of the Roman road, called Watling-ſtreet, paſſed through this town. The principal ſtreet is broad; from which branch off two others at right angles; in which are many good ſhops, and a bridge over the river, that, about thirty years ago, was widened and rendered more commodious at the expence of the county. The flouriſhing ſtate of the town has chiefly ariſen from the different mills which have been erected here for manufacturing gun-powder and paper. The original paper-mill, erected by ſir John Spielman, about half a mile above the bridge, occupied the ſite of the preſent powder-mills; and another mill, at a ſhort diſtance below, ſtands where Geoffroy Box of Liege erected, as early as the year 1590, a mill for ſlitting iron bars into rods. The town has a well-ſupplied market weekly, on Saturday, and a fair on the 2d of Auguſt. The number of houſes, as appears by the returns made under the late act of 1800, amounted

amounted to 468; occupied by 2406 inhabitants. See Haſted's Hiſt. of Kent.

DARTMOOR, in the county of Devon, England, is a large waſte and foreſt, extending from Cheyford, near the banks of the Tamar, to Taviſtock, in the vale of Exeter. The length is about twenty miles, and the breadth fourteen; and includes between two and three hundred thouſand acres of open, uncultivated lands. The ſurface is wildly and wonderfully varied. It ſwells in bold eminences from fifteen to eighteen hundred feet high, and again deſcends into hollow glens and cavities. Approaching from the ſouth and ſouth-eaſt, the eye is bewildered by viewing an extenſive tract, exhibiting ſudden hills, called *torrs*, ſurfaces covered with immenſe rugged rocks, and vaſt maſſes of granite, which lie ſcattered around, as though precipitated from the declivities into the vallies beneath. So confuſedly are theſe huge fragments ſtrewed, and ſo varied their appearance, that they have been compared to ſtones ejected from volcanoes, and wrecks of primæval mountains, torn in pieces by the "war of elements." In the higher parts of the moor, to the north-weſt, are large tracts of ſwampy land, exceedingly dangerous to cattle, which depaſture the ſcanty herbage; but yield a conſtant ſupply of fuel to the poor cottagers, from the immenſe beds of peat, which lie beneath the ſurface. The inhabitants are called *moormen*, who keep a few ſheep and cattle on the moor, and look after the flocks and herds of others. The right of depaſturage belongs to different intereſts. The foreſt, ſtrictly ſo called, is the property of the prince of Wales, as parcel of the duchy of Cornwall; but the outſkirts are appendant to the ſurrounding manors: ſome of which claim a right by preſcription of common within the foreſt, by paying a ſmall annual ſum to the duchy, called *venville* or *fenfield* money.

Though, as the name ſuggeſts, it was once well clothed with timber, the only remaining natural wood is an aſſemblage of dwarf ſcrubby oaks, interſperſed with mountain-aſh trees, willows, and underwood. Within a few years, ſome thouſands of acres have been grubbed up, and numerous young plantations formed. Much land has alſo been converted into tillage by the command of his royal highneſs, under the direction of colonel Tyrwhit. *Cruckern Tor* has long been celebrated as the place where the ſtannary-courts, or parliaments, were held for this county; whence Mr. Polwhele conjectured, that it had been a ſeat of Britiſh judicature prior to the Roman invaſion.

On this moor there is now erecting a large priſon, which is intended to be appropriated to thoſe unfortunate perſons who are captured in times of war. The building is upon an immenſe ſcale, and is erecting from the deſigns of Mr. Alexander, a ſcientific architect. At various places on this extenſive tract, are the ſhafts of ſeveral exhauſted and neglected tin mines; and in the vicinity of Taviſtock are ſome now working. See Polwhele's Hiſtory of Devonſhire; alſo the Beauties of England and Wales, vol. iv.

DARTMOUTH, is a borough, ſea-port, and market town, in the county of Devon, England; 30 miles diſtant from Exeter, and 203½ weſt from London. It formerly was the property of Judhael de Totneſs, to whom the manor was granted by the Conqueror. The town firſt ſent members to parliament in the time of Henry I.; but not regularly till the reign of Edward III., who granted it a charter of incorporation; under which authority it is governed by a mayor, recorder, two bailiffs, and twelve common-council men, with other inferior officers. In the corporation is veſted the right of election, and the power of creating burgeſſes. This place was deſtroyed by fire in the reign of Richard I., and again in the reign of Henry IV. In both inſtances it was by French incendiaries, who eſcaped with little loſs; but attempting it a third time, in the year 1404, they were intercepted by the peaſantry and women; and the whole party either killed or taken, with their leader, Monſ. de Coſtell. The town originally conſiſted of three villages, Clifton, Dartmouth, and Hardneſs; and, though united by buildings, yet in many reſpects, as to local regulations, they were diſtinct. From the natural ſituation of the place, a craggy hill, many of the ſtreets are aukward, and moſt of them incommodiouſly narrow, and the lower tier of houſes frequently communicates with thoſe above by flights of ſteps. The principal one which faces the quay, is occupied by the merchants. Dartmouth has three churches, and a meeting-houſe for diſſenters. St. Clement's church is ſituated upon a hill above the town, and having a tower 70 feet high, forms an excellent ſea-mark. Here are three charity ſchools for the education of poor children.

The river Dart, opening into a fine eſtuary, forms an excellent and ſafe harbour, ſufficiently capacious to admit five hundred ſail of ſhipping. The entrance is defended by a caſtle, and two fortified platforms; but the fortreſs is not large, and few guns are mounted. A number of veſſels are employed in the pilchard-fiſhery, and the town has an export trade from Newfoundland to the Mediterranean; whence it imports wine, oil, fruits, &c. The number of ſhips belonging to this port is about 350, which gives employment to upwards of 3000 men; a certain number of whom the proprietors are obliged by law to ſelect from landſmen, by which means the trade becomes an excellent nurſery for the navy. The regular market is on Friday, but a well ſupplied fiſh-market is held every day, except Sunday. By the returns under the late act, the number of houſes was 460, and inhabitants 3412.

To the north of the harbour lies Torbay, the celebrated and general rendezvous of the Britiſh grand fleet; where, in unfavourable weather, it generally comes to an anchor, and rides in ſafety during the ſtorm. At the lower part of the bay, on the finely-wooded ſhore, is the ſtately manſion of George Carey, eſq. called Tor Abbey, formerly a religious houſe, founded by William de Bruer, in the time of king John; part of the ruins yet remain. And in the pariſh is Kentſhole, a ſeries of caverns, connected by ſubterraneous paſſages, about 1100 feet from the entrance, through one of which paſſes a rivulet.

DARTMOUTH, a town of America, in the ſtate of New Hampſhire, and county of Grafton, N.W. of the foot of the white mountains; 33 miles N.E. of Haverhill, and 87 W. of Portſmouth. In 1790, it contained 111 inhabitants, and was incorporated in 1772.—Alſo, a thriving ſea-port town in the county of Briſtol, and ſtate of Maſſachuſetts, ſituated on the W. ſide of Accuſhnet river, 62 miles ſoutherly of Boſton, incorporated in 1664, and containing 2660 inhabitants. N. lat. 41° 37′. W. long. 70° 52′.—Alſo, a town of Elbert county in Georgia, ſituated in the peninſula formed by the confluence of Broad and Savannah rivers, two miles from fort James, Dartmouth, a mile below Charlotte fort. The town and fort derive their names from James, earl of Dartmouth, who obtained a grant and powers to the Indian trading company in Georgia to treat with the Creeks for the territory called the "New Purchaſe," ceded in diſcharge of debts due to the traders. This treat contains about 2,000,000 acres, lying upon the head of the great Ogechee, between the banks of the Savannah and Alatamaha, touching on the Oconee, including all the waters of Broad and Little rivers. This territory comprehends excellent fertile land, well watered by many rivers, creeks, and brooks.

DARTMOUTH *College*. See COLLEGE.

DARTOS, in *Anatomy*, a ſuppoſed muſcular expanſion, deſcribed as exiſting between the integuments of the ſcrotum and

and the teſtes. It is well known that the application of cold to the ſurface of the body produces a corrugation of the ſcrotum; and this motion was aſcribed by the older anatomiſts to muſcular fibres exiſting in the ſituation juſt alluded to. The more accurate inveſtigations of the moderns have decided, that this ſuppoſed muſcular dartos is nothing but ſimple cellular texture, which being entirely free from fat, and thereby poſſeſſing a ſtringy and fibrous appearance, and often having a reddiſh colour from the numerous blood-veſſels, whoſe ramifications it contains, contracts an appearance ſomewhat reſembling that of muſcular fibres. The motion taking place under the circumſtances of cold applied externally, &c., ſeems to be analogous to what occurs in the ſurface of the body in general; where a contracted ſtate of the integuments is produced, together with a peculiar roughneſs of the ſkin, giving riſe to the appearance called cutis anſerina, and taking place independently of any muſcular contraction.

DARU, in *Botany*, a name given by Avicenna and Serapion to a ſpecies of turpentine tree, which the latter author calls the lentiſk. This grew up to a very large tree, and bore a much larger and more beautiful fruit than the common turpentine-tree.

Daru, in *Geography*, a town of Perſia, in the province of Kerman; 90 miles N. E. of Sirgian.

DARVERNUM, in *Ancient Geography*. See Durovernum.

DARWAR, or Danwar, in *Geography*, a conſiderable fortreſs of Hindooſtan, in the country of Sanore, one of Tippoo's frontier towns, towards the dominions of the Paiſhwah; 88 miles S. of Viſiapour, and 90 E. N. E. of Goa. N. lat. 16° 5′. E. long. 75° 9′.

DARWEN, a river in England, in the county of Lancaſter, which runs into the Ribble, near Preſton.

DARWENT. See Derwent.

DARWIN, Erasmus, in *Biography*, equally famed as a phyſician and a poet, was a native of Elton, near Newark, Nottinghamſhire, where he was born December 12, 1731. After going through the uſual ſchool education, under the Rev. Mr. Burrows, at the grammar-ſchool at Cheſterfield, with credit, he was ſent to St. John's College, at Cambridge. There he only continued until he took his bachelor's degree in medicine, when he went to Edinburgh, to complete his ſtudies; which being finiſhed, and having taken the degree of doctor in medicine, a profeſſion to which he was always attached, he went to Litchfield, and there commenced his career of practice. Being ſent for, ſoon after his arrival, to Mr. Inglis, a gentleman of conſiderable fortune in the neighbourhood, who was ill with fever, and in ſo dangerous a ſtate, that the attending phyſician had given up the caſe as hopeleſs, the doctor had the good fortune to reſtore him to health. This gave him ſo high a degree of reputation at Litchfield, and in the neighbouring towns and villages, that his competitor, who was before in conſiderable practice, finding himſelf neglected, and nearly deſerted, left the place. Dr. Darwin ſoon after married Miſs Howard, the daughter of a reſpectable inhabitant of Litchfield, by which he ſtrengthened his intereſt in the place. By this lady he had three ſons, who lived to the age of manhood; two of them he ſurvived; the third, Dr. Robert Waring Darwin, is now in conſiderable practice as a phyſician at Shrewſbury. In 1781, our author having married a ſecond wife, removed to Derby, where he continued to reſide to the time of his death, which happened on Sunday the 18th of April, 1802, in the ſeventieth year of his age. Six children by his ſecond lady, with their mother, remain to lament the loſs of him.

The doctor was of an athletic make, much pitted with the ſmall-pox. He ſtammered much in his ſpeech. He had enjoyed an almoſt uninterrupted good ſtate of health, until towards the concluſion of his life, which he attributed, and reaſonably, to his temperate mode of living, particularly to his moderation in the uſe of fermented liquors. This practice, he recommended ſtrenuouſly to all who conſulted him. Miſs Seward, from whoſe Memoirs of the Life of Dr. Darwin theſe notices are principally taken, gives him the credit of having introduced habits of ſobriety among the trading part of Litchfield, where it had been the cuſtom to live more freely, before he went to reſide there.

His frequent journies, into the country on profeſſional buſineſs, contributed alſo in no ſmall degree to the preſervation of his health and his faculties, which latter remained unimpaired to the day of his death. His death was ſudden, occaſioned by a fit of what he was uſed to call angina-pectoris, which he had ſeveral times experienced, and always relieved by bleeding plentifully.

As Dr. Darwin was a votary to poetry, as well as medicine, he occaſionally ſent his effuſions in that way, to one or other of the monthly publications, but without his name, conceiving, from the example of Akenſide and Armſtrong, that the reputation he might acquire by his poetry, would operate as a bar to his advancement in the practice of medicine. His "Botanic Garden," in which he celebrates what he calls the Loves of the Plants, the firſt of his poems to which he put his name, was not publiſhed until the year 1781, when his medical fame was ſo well eſtabliſhed, as to make it ſafe for him to indulge his taſte in any way he ſhould chuſe. Beſides, the poem was ſo amply furniſhed with notes, containing the natural hiſtory, and accounts of the properties of plants, that it did not ſeem very alien from his profeſſion. The Botanic Garden is compriſed in two parts. In the firſt the author treats of the Economy of Vegetables, in the ſecond of the Loves of the Plants. The novelty of the deſign, the brilliancy of the diction, full of figurative expreſſions, in which every thing was perſonified, rendered the poem, for ſome years, extremely popular. But the fame which it acquired has in a great degree ſubſided, and it is now little noticed. It is probable, that an ingenious little poem, the Loves of the Triangles, publiſhed in a monthly journal, which is a happy imitation of the Darwinian manner, contributed to its decline.

In 1793, the author publiſhed the 1ſt volume of "Zoonomia, or the Laws of organic Life," 4to. The 2d volume which completed the author's plan, was printed in the year 1796. As the eccentric genius of the author was known, great expectations were formed of this work, the labour we were told of more than twenty years. It was to reform, or entirely new model, the whole ſyſtem of medicine, profeſſing no leſs than to account for the manner in which man, animals, and vegetables are formed. They all, it ſeems, take their origin from living filaments, ſuſceptible of irritation, which is the agent that ſets them in motion. Archimedes was wont to ſay, give me place to ſtand on, and I will move the earth. Such was his confidence in his knowledge of the power of the lever. Our author ſaid, give me a fibre ſuſceptible of irritation, and I will make a tree, a dog, a horſe, a man. "I conceive," he ſays, Zoonomia, vol. i. p. 492, "the primordium, or rudiment of the embryon, as ſecreted from the blood of the parent, to conſiſt in a ſingle living filament, as a muſcular fibre, which I ſuppoſe to be the extremity of a nerve of loco-motion, as a fibre of the retina is the extremity of a nerve of ſenſation; as, for inſtance, one of the fibrils which compoſe the mouth of an abſorbent veſſel; I ſuppoſe this living filament, of whatever form it may be, whether ſphere, cube, or cylinder, to be endued with the capacity of being excited into action, by certain kinds of ſtimulus. By the ſtimulus of the ſurrounding fluid in which it is received from

from the male, it may bend into a ring, and thus form the beginning of a tube. This living ring may now embrace, or abſorb a nutritive particle of the fluid in which it ſwims, and by drawing it into its pores, or joining it by compreſſion to its extremities, may increaſe its own length or craſſitude, and, by degrees, the living ring may become a living tube. With this new organization, or accretion of parts, new kinds of irritability may commence," &c.; whence, ſenſibility which may be only an extenſion of irritability, and ſenſibility further extended, beget perception, memory, reaſon, and in ſhort all thoſe faculties which have been, it ſeems, erroneouſly attributed to mind, for which, it appears, there is not the ſmalleſt neceſſity; and as the deity does nothing in vain, of courſe ſuch a being does not exiſt. It would be uſeleſs to enter into a further examination of the Zoonomia, which has long ceaſed to be popular; thoſe who wiſh to ſee a complete refutation of the ſophiſms contained in it will read with ſatisfaction, "Obſervations on the Zoonomia of Dr. Darwin, by Thomas Brown, Eſq." publiſhed at Edinburgh in 8vo. in 1798. In 1801, the author publiſhed Phytologia, or the Philoſophy of Agriculture and Gardening; but the public, tired with the reveries of the writer, let this large book of 600 pages in 4to. paſs almoſt unnoticed. As little attention was paid to a ſmall tract on female education, which had little indeed to attract notice. "It is," Miſs Seward obſerves, "a meagre work, of little general intereſt, thoſe rules excepted which are laid down for the preſervation of health." It is however harmleſs, a character that can by no means be accorded to the Zoonomia, as may be gathered from the ſtrictures we have thought it neceſſary to paſs on that work. Seward's Memoirs of the Life of Dr. Darwin; alſo Medical Commentaries and Annals.

Darwin, Mr. Charles, one of the ſons of Dr. Eraſmus Darwin, who died at Edinburgh the 15th of May, 1778, while proſecuting his ſtudies in medicine, deſerves to be noticed, for having diſcovered a teſt, diſtinguiſhing pus from mucus, for which a gold medal was adjudged him by the univerſity. "As the reſult of numerous experiments," he ſays, "when any one wiſhes to examine the matter expectorated by his patient, let him diſſolve a portion of it in vitriolic acid, and another portion of it in cauſtic alkaline lixivium, and then add pure water to both ſolutions; if there is a precipitation in each ſolution, it is clear the expectorated matter is pus; if there is no precipitation, the matter is ſimply mucous. Mr. Darwin left an unfiniſhed eſſay on the retrograde motion of the abſorbent veſſels of animal bodies in ſome diſeaſes. This was, ſome time after the death of the young man, publiſhed by his father, together with the diſſertation for which he had obtained the prize medal.

DASÆ, in *Ancient Geography*, a town of Arcadia, the mines of which contributed to the aggrandizement of Megalopolis; which lay N.E. of it.

DASCHITZ, in *Geography*, a town of Bohemia, in the circle of Chrudim; 7 miles N.N.E. of Chrudim.

Daschitz, or *Datſchitz*, a town of Moravia, in the circle of Iglau; 6 miles N. of Zlabins.

DASCILITIDES, in *Ancient Geography*, a lake of Aſia Minor, in Myſia; which, according to Plutarch, was near Cyzicum. This lake belonged partly to the Byzantins, and partly to the Cyzicenians, according to Strabo. It was alſo called *Aphnites*.

DASCON Sinus, a gulf ſo called by Diodorus, which lay on the eaſtern coaſt of Sicily, near Syracuſe.

DASCUSA, a town of Aſia, ſeated on the banks of the Euphrates, having 38° 15′ of latitude.

DASCYLIUM, Diaskileo, a town of Aſia in Bithynia, ſituated near the lake Daſcilitides. Steph. Byz. mentions four other towns of this name; one founded ſoon after the city of Troy; another in Ionia; a third of Caria; and a fourth on the confines of the Eolide and Phrygia.

DASHUR, in *Geography*, a town of Egypt; 15 miles S. of Cairo.

DASSARATÆ, in *Ancient Geography*, a people placed by Plutarch towards the confines of Macedonia and Illyria, near the river Lycus.

DASSAWN, in *Geography*, a river of Hindooſtan, which runs into the Betwha; 16 miles W. of Raat.

DASSDORF, a ſmall town of Saxony, in the principality of Saxe-Weimar.

DASSEL, a ſmall town of the kingdom of Weſtphalia, in the late principality of Hildeſheim, which was aſſigned as an indemnity to Pruſſia by the treaty of Luneville, and loſt again by Pruſſia at the peace of Tilſit. Daſſel is ſituated in a deep vale on the Spoling, which not far from thence flows into the river Ilme, in a fertile diſtrict called the Hundeſruck.

DASSEN, an iſland in the Atlantic, near the coaſt of Africa, between the Cape of Good Hope and Saldanha bay. S. lat. 33° 26′. E. long. 72°.

DASTARGEDA, or Artemita, in *Ancient Geography*, *el-Melik*, a town of Aſia, on the left bank of the river Delas, north of its mouth in the Tigris, and S.W. of Apollonia. Choſroes, king of Perſia, had a palace in this town, which he preferred to that of Cteſiphon. This palace was deſtroyed by Heraclius.

DASTIRA, a town of Armenia Major. Strabo.

DAST-Surab, in *Geography*, a town of Perſia, in the province of Farſiſtan; 70 miles S. of Schiras.

DASYMMA, a ſuperficial inequality of the inner part of the eye-lids, accompanied with a redneſs. Blancard derives it from δασυς, *hirſutus*.

DASYPUS, in *Zoology*, a genus of mammalia, in the bruta family. They have no tuſks; the grinders are ſhort, cylindrical, and from ſeven to eight in each jaw; and the body covered with a bony ſhell divided into zones. Theſe are the armadillo of Engliſh writers.

There is only a ſmall number of ſpecies in this genus, and thoſe are chiefly inhabitants of South America. They are readily diſtinguiſhed from all other quadrupeds, by the ſingular bony covering or ſuit of banded armour with which nature has at once protected and adorned theſe curious animals; their ſhelly coat being of conſiderable ſtrength, and ſo admirably contrived as to accommodate itſelf to every poſture and motion of the body. The armadillos are of a gentle diſpoſition, and inhabit ſubterraneous retreats or burrows, which they eaſily excavate by means of their large and ſtrong claws. They feed on roots, melons, potatoes, grain, fleſh, inſects, and worms, in queſt of which they wander abroad chiefly in the night time, as they reſt during the day in their burrows and hiding-places. As they are themſelves conſidered excellent food, they are ſought after, and dug out of their ſubterraneous cavities, and ſold for the table. They are, however, only the young armadillos which are in requeſt for this purpoſe; for as they grow old, the fleſh acquires a ſtrong muſky ſcent, which renders them very diſagreeable. When attacked, the armadillos roll themſelves up into the form of a ball, and are thus ſecured in an effectual manner from ordinary accidents. They are ſaid to drink frequently, and often grow extremely fat; they are alſo repreſented to be extremely prolific, producing a brood of ſeveral young every month, or at leaſt three or four times in a year. The ſpecies are diſtinguiſhed principally by the number of zones or bands.

Species.

TRICINCTUS. Bands three, moveable; toes five. Houtt. *Cataphractus ſcutis duobus, cingulis tribus*, Briſſ. *Tatou*, Redi. *Tatu ſ. armadillo orientalis*, Seba. *Tatu apara*, Marcgr. Three-banded armadillo.

This may be conſidered as one of the moſt elegant ſpecies of armadillo; its colour is a clear yellowiſh-white; the head, ſhoulders, and poſterior part of the body are coated with regular hexagonal diviſions, curiouſly ſtudded or tuberculated on the ſurface, and the zones of the body are extremely diſtinct; the tail is thick and ſhort; the legs are covered with hexagonal diviſions or ſegments, ſimilar to thoſe on the ſhoulders, but ſmaller; the ears are rather large; and the claws ſmaller than in moſt other ſpecies. This kind is a native of Brazil, and feeds on fruits and poultry.

QUADRICINCTUS. Bands four. Gmel. *Cataphractus*, Briſſ. *Chæloniſcus*, Column.

An uncertain ſpecies, by ſome conceived to be a variety of the former.

SEXCINCTUS. Bands ſix; feet five-toed; Linn. Schreber, &c. *Tatu et tatu-paba Braſilienſibus*, Marcgr. *Encouvert ou tatou à ſix bandes*, Buff. Six-banded armadillo.

Reſembles daſypus tricinctus, but is furniſhed with ſix bands inſtead of three; the tail is very thick at the baſe, and ſhort in proportion to the animal; the claws large and ſtrong. The general colour is reddiſh-yellow. It infeſts plantations in South America; is eatable, and feeds on fruits and roots. A ſuppoſed variety of this kind, in the Britiſh Muſeum, having eight inſtead of ſix bands, may probably prove to be a diſtinct ſpecies.

SEPTEMCINCTUS. Bands ſeven; toes on the anterior feet four: poſterior feet five. Linn. *Tatus quadrupes peregrina*, Geſn. Seven-banded armadillo.

Inhabits India and South America; and is believed to be a variety of the nine-banded armadillo.

OCTOCINCTUS. Bands eight; ſhields two. Schreber. *Cataphractus ſcutis duobus, cingulis octo*, Briſſ.. *Aiatochtli*, Hernand. *Tatouette ou tatou à huit bandes*, Buff. Eight-banded armadiilo.

This kind inhabits Brazil, and is eſteemed delicious. The ſhields are ſprinkled with prominent white knobs; belly whitiſh; ſuppoſed to be a variety of the following ſpecies:

NOVEMCINCTUS. Bands nine; anterior feet four-toed; poſterior feet five-toed. Linn. *Tatus*, Geſn. *Cachicame, ou Tatou à neuf bandes*, Buff. Nine-banded armadillo.

The fleſh of this ſpecies is delicate. The cruſt on the ſhoulders, rump, and head marked with ſix-ſided figures. It inhabits South America.

DUODECIMCINCTUS. Bands twelve; toes five. *Daſypus unicinctus*, Linn. *Tatu ſeu armadillo africanus*, Seba. *Kabaſſou ou tatou à douze bandes*, Buff.

The length of this animal from the noſe to the tail is about a foot, and the tail nearly ſeven inches long. An armadillo, ſuppoſed to be a variety of this, is mentioned by Pennant under the name of the greater twelve-banded armadillo, which meaſures from the tip of the noſe to the tail two feet ten inches, and the tail twenty inches. The head in both kinds is remarkably blunt, and the ears large.

18-CINCTUS. Bands eighteen. *Cirquincon, ou Tatou à dix-huit bandes*, Buff. Eighteen-banded armadillo. Penn.

Deſcribed by Grew in the laſt century under the name of the weazel-headed armadillo, from a ſpecimen in the muſeum of the Royal Society.

It appears to be allied to the twelve-banded armadillo, and does not ſeem to be figured by any author except Grew.

DASYS, Δασυς, denſe, thick, cloſe, rough, in Prorrhet. and Coac. is an epithet for a tongue condenſed, contracted, and exaſperated with heat and dryneſs, as it happens in phrenſies. James's Med. Dict.

DATA, in *Mathematics*, certain things, or quantities, ſuppoſed to be given, or known, in order, from them, to find out other things or quantities, which are unknown, or ſought for. A problem, or queſtion, generally conſiſts of two parts; data and quæſita.

Euclid has an expreſs treatiſe of data; wherein he uſes the word for ſuch ſpaces, lines, and angles, as are given in magnitude, or to which we can aſſign others equal.

From the primary uſe of the word data in mathematics, it has been tranſplanted into other arts; as philoſophy, medicine, &c. where it expreſſes any quantity, which, for the ſake of a preſent calculation, is taken for granted to be ſuch, without requiring an immediate proof for its certainty; called alſo the given quantity, number, or power. And hence alſo ſuch things as are known, from whence either in natural philoſophy, the animal mechaniſm, or the operation of medicines, we come to the knowledge of others unknown, are now frequently in phyſical writers called data.

DAT-AL-SAMIN, in *Geography*, a town of Arabia, 250 miles of Cathem.

DATAMES, in *Biography*, a diſtinguiſhed military commander, who firſt ſerved among the guards of Artaxerxes Mnemon, and was afterwards employed in the war againſt the Caduſians. In this buſineſs he gained ſo much credit, and ſo high a name, that he was appointed governor of that part of Cilicia which borders upon Cappadocia. Datames was afterwards appointed to reduce Thyus, who had revolted againſt the king: he performed the duty, and took his opponent priſoner, who was a very tall and ſtout man, and of a terrible aſpect. He cauſed him to be dreſſed in the robes of a ſatrap, and decorated with a gold chain and bracelets, and at the ſame time, putting himſelf into the ruſtic attire of a huntſman, with a club in one hand, and a cord in the other, to which Thyus was faſtened, led him into the royal preſence as if he were a wild beaſt. The king was highly pleaſed with the incident, and appointed Datames to be chief in the Egyptian war; but while preparations were making, he was ordered to go in queſt of Aſpis, who had revolted from his allegiance. The ſucceſs and high merit of Datames excited the envy of the courtiers, who combined to ruin him. Datames, apprized of their intentions, reſolved to be before hand with them, by quitting the king's ſervice, and making himſelf independent. His own ſon was the firſt to carry the news to court of his father's rebellion. The king ſent againſt him a very numerous army, but it was unſucceſsful, and the moſt it could extort was the nominal ſubmiſſion of Datames, who in every engagement proved himſelf the ſuperior. Artaxerxes could not be reconciled to the rebellious general, and as he found himſelf incapable of conquering him, he determined to adopt the means of treachery, by which he finally accompliſhed his end. Datames was aſſaſſinated by the hands of Mithridates, who, in concert with the king, pretended to be an open enemy of his ſovereign, while he was ſeeking the means of performing what lay neareſt his heart. Cornelius Nepos.

DATE, an addition, or appendage, in writings, acts, inſtruments, letters, &c. expreſſing the day and month of the year, when the act, or letter, was paſſed or ſigned; together with the place where the ſame was done.

The word is formed from the Latin datum, given, the participle of do, I give. The Latins uſually ſay dabam, I gave.

In writings of importance the date ſhould be written in words

words at length; dated or given at London this twenty-ſixth day of March, in the year of our Lord one thouſand ſeven hundred and fifty. In letters, the date is uſually in figures; London, March the 26th, 1750.

An antedate is a falſe date, prior to the real time when the inſtrument was paſſed, or ſigned.

A poſt-date, is that poſterior to the real time, &c.

Our ancient deeds had no dates, but only the month and year, to ſignify that they were not made in haſte, or in the ſpace of a day, but upon longer and more mature deliberation. The king's grants began with theſe words, "Præſentibus & futuri, &c." but the grants of private perſons with "Omnibus præſentes literas inſpecturis, &c."

A deed is good though it mentions no date, or hath a falſe date: or even if it hath an impoſſible date, as the 30th of February; provided the real day of its being dated or given, that is, delivered, can be proved. Blackſt. Com. vol. ii. p. 304.

DATE, *Dactylus*, the fruit of the palm-tree. See PHŒNIX.

The word is formed of dacte, and that of dactylus, finger; as being round and oblong, reſembling a finger's end.

This fruit is gathered in autumn, before it is ripe; and bears a near reſemblance to our bullace; being of a green colour, and very ſharp and aſtringent. When ripe, it becomes ruddy, having a hard, longiſh ſtone, cloven at bottom, and encompaſſed with a thin white pellicle, or ſkin.

The huſk, or covering of the date, called by the ancients elate, or ſpatha, when the fruit is in its growth, is variable; having as many changes of colour as the fig has. Some dates are black, ſome white, ſome brown; ſome again are round like apples, and very big. Ordinarily they are oblong, fleſhy, yellow, ſomewhat bigger than the thumb's end, and ſome are very agreeable to the taſte. Some are no bigger than a chich-pea, and others as big as a pomegranate. The beſt are thoſe called royal dates. There is alſo another ſort called caryotæ, which are very good. Some of them have ſtones, and others none.

Our dates are brought us from Egypt, Syria, Africa, and the Indies. Among the Egyptians and Africans they make a principal article of food. They never come to full maturity in Italy, or the moſt ſouthern parts of Spain; and yet there are tolerable dates in Provence; which do not keep, but breed worms. The beſt come from Tunis and Perſia.

DATE-*palm*, in *Botany*. See PHOENIX.

DATE *plum*. See DIOSPYROS.

DATES, *Land of*. See BILEDULGERID.

DATHOLITE. The colour of this mineral is greyiſh and greeniſh-white, paſſing into mountain-green. It occurs in maſs, and cryſtallized in ſmall rectangular tetrahedral priſms with truncated angles. It is tranſlucent. Its luſtre internally is ſhining, between vitreous and reſinous. Its fracture is ſmall and imperfectly conchoidal. It preſents large and coarſe granular concretions. It is conſiderably hard. Sp. gr. 2.98.

It is compoſed, according to Klaproth, of

36.5	Silex
35.5	Lime
24.	Boracic acid
4.	Water.
100.	

It has been recently diſcovered by Eſmark, at Arendahl in Norway.

DATHTHA, in *Ancient Geography*, a town of Aſia, in the interior of Media. Ptolemy.

DATISCA. in *Botany*, baſtard hemp. Linn. Gen. 530. Schreb. 700. Willd. Sp. Pl. v. 4. 823. Juſſ. 445. Gærtn. t. 30. Claſs and order, *dioecia decandria*. Nat. Ord. uncertain.

Gen. Ch. Barren fl. *Cal.* of five equal, linear, acute leaves. *Cor.* none. *Stam.* Filaments about 15, very ſhort; anthers oblong, obtuſe, much longer than the calyx. Fertile fl. *Cal.* ſuperior, of two teeth, erect, minute, permanent. *Cor.* none. *Piſt.* Germen oblong, inferior; ſtyles three, ſhort, cloven; ſtigmas ſimple, oblong, ſhaggy. *Peric.* Capſule priſmatic, three-pointed, with three valves and one cell. *Seeds* numerous, ſmall, ranged along three, four, or five linear, parallel ribs in the capſule.

Eſſ. Ch. Barren fl. Calyx five-leaved. Corolla none. Anthers fifteen, oblong, nearly ſeſſile. Fertile fl. Cal. of two teeth. Cor. none. Styles three. Capſule inferior, triangular, three-horned, pervious, of one cell, with many ſeeds.

Of this genus there are two ſpecies. D. *cannabina*, (Cannabis lutea fertilis; Alpin. Exot. t. 298.) has a ſmooth ſtem, and grows in Crete. It is perennial, herbaceous, ſeveral feet high, with much of the habit of hemp, ſee CANNABIS; but the flowers are yellow and more conſpicuous than thoſe of that uſeful plant. Leaves alternate, pinnate, jagged. It flowers after midſummer, and is propagated by parting the roots in autumn, as well as by ſeeds; but the latter can only be perfected when the barren and fertile plants are cultivated together, whence Linnæus drew one proof of his doctrine of the ſexes of plants. See his Diſſertation on that ſubject, publiſhed in Engliſh, Lond. 1786, 8vo. D. *hirta*, a larger ſpecies, with a hairy ſtem, is found in Pennſylvania. This differs little in general appearance from the former.

DATISI, in *Logic*, a mode of ſyllogiſms in the third figure, wherein the major is an univerſal affirmative, and the minor and concluſion are particular affirmative propoſitions. E. gr.

DA "All God's friends are kings."
TI "Some of God's friends are poor."
SI "Therefore, ſome poor are kings."

DATIVE, in *Grammar*, the third caſe in the declenſion of nouns; expreſſing the ſtate or relation of a thing, to whoſe profit or loſs ſome other thing is referred.

It is called dative, becauſe uſually governed by a verb implying ſomething to be given to ſome perſon. As, commodare Socrati, to lend to Socrates; utilis reipublicæ, uſeful to the commonwealth; pernicioſus eccleſiæ, pernicious to the church; viſum eſt Platoni, it ſeemed to Plato, &c.

In Engliſh, where we have properly no caſes, this relation is expreſſed by the ſign to or for.

DATOS, or DATON, in *Geography*, a town of Europe, which, after having belonged to Thrace, was transferred to the king of Macedonia, when the empire was extended on that ſide; it was ſituated near mount Pangæa, on a craggy hill, having a foreſt to the north, and to the ſouth a lake or marſh, at a ſmall diſtance from the ſea; to the eaſt there were defiles, and to the weſt, a fertile and pleaſant plain, which extended as far as Strymon. Fabulous tradition ſays, that Proſerpine was gathering flowers here when ſhe was forcibly carried away by Pluto. This place was proverbially rich, on account of the mines of gold in its territory. It was at firſt called *Cremides*, from the fountains that abounded in the hill on which it was built; and afterwards, as is ſaid, Calliſtratus the Athenian gave it the name of Datos. When Philip, king of Macedon, took poſſeſſion of it, he fortified

it, and called it Philippi. It became famous for the battle fought under its walls between the troops of Brutus and Caſſius, and for thoſe of Octavius. The territory, on which are ſeen the ruins of Philippi, is now called *Philipp-ghi*, Φιλλιππε γη, that is, the land of Philippi.

DATTEAH, a town of Hindooſtan, in the circar of Gohud; 96 miles S. of Agra.

DATURA, in *Botany*, thorn-apple (from the American name of this plant, of ſimilar ſound, made claſſical by Linnæus from *do, dare, daturus*, becauſe it is *given* as a ſtimulant). Linn. Gen. 98. Schreb. 3. Willd. Sp. Pl. v. i. 1007. Juſſ. 125. Claſs and order, *pentandria monogynia*. Nat. Ord. *Luridæ*, Linn. *Solaneæ*, Juſs.

Gen. Ch. *Cal.* of one leaf, inferior, tubular, five-angled, five-toothed; its baſe permanent. *Cor.* of one petal, funnel-ſhaped; tube cylindrical, about as long as the calyx; limb dilated, plaited, with five angles, and five little acute teeth. *Stam.* Filaments five, equal, awl-ſhaped, inſerted into the tube of the corolla, and ſhorter than its limb; anthers oblong, flattened, obtuſe. *Piſt.* Germen ovate, ſuperior; ſtyle thread-ſhaped, ſtraight; ſtigma obtuſe, of two plates. *Peric.* Capſule ovate, ſtanding on the baſe of the calyx, of two cells and four valves; receptacles tranſverſe with reſpect to the partitions, dilated, dotted. *Seeds* numerous, kidney-ſhaped.

Eſſ. Ch. Corolla funnel-ſhaped, plaited. Calyx tubular, angular, partly deciduous. Capſule ſuperior, of two cells and four valves.

D. *ſtramonium*, common thorn-apple, Engl. Bot. t. 1288. Curt. Lond. faſc. 6. t. 17. though originally a native of America, is now a frequent weed on dunghills and cultivated ground in various parts of Europe. It is an annual, of rank growth, and of a fœtid ſmell when bruiſed. Leaves flaccid, ovate, ſinuated, alternate. Flowers ſolitary, ſtalked, white, fragrant at certain times. Fruit very ſpinous. Its qualities are narcotic and dangerous. D. *faſtuoſa*, purple thorn-apple, from the Eaſt Indies, is cultivated in our ſtoves for the ſake of its flowers, which are handſome, fragrant, purple without, white within, and often furniſhed with a triple corolla. D. *arborea*, tree thorn-apple, is a magnificent arboreſcent ſpecies, a native of Peru and Chili, whoſe white flowers expand only at night, when they are very fragrant. Each is often two feet in length, and we have ſeen 150 open at a time on one tree. Leaves oblong, nearly entire. Capſules ſmooth. It is eaſily cultivated in a bark ſtove, where it ſoon becomes a weed. Six or ſeven more ſpecies are known.

DATURA, in *Gardening*, compriſes plants of the herbaceous flowery annual kind; of which the ſpecies moſtly cultivated are the common thorn-apple (D. *ſtramonium*), the blue thorn-apple (D. *tatuta*), the purple thorn-apple, (D. *faſtuoſa*), the hairy thorn-apple (D. *metel*), and the tree thorn-apple. Theſe are moſtly tall growing plants not very difficult of culture.

Method of Culture.—Theſe are plants which are propagated annually, by ſowing the ſeeds of the two firſt or hardy ſorts in the clump-borders, or other places where the plants are to remain, in patches of four or five together, covering them in to the depth of nearly half an inch. When the plants are up, the weakeſt ſhould be removed, ſo as to leave only one or two of the ſtrongeſt in each place; but the ſeeds of the latter or tender ſorts ſhould be ſown in the ſpring ſeaſon, as the latter end of March or beginning of the following month, either on a hot-bed covered by frames and glaſſes, or in pots, and managed as other tender annuals, admitting air to them freely in their early growth, and when ſome inches high, removing them into ſeparate pots, replunging them in the hot-bed, ſo formed as to draw them up to a pretty tall growth. When the weather becomes ſettled warm, as about June, they may be removed into the open air, being previouſly hardened in a gradual manner by due expoſure, either in the pots, or planted out in the borders or other places, with balls of earth about their roots. The two firſt kinds are the beſt ſuited to the laſt method of management.

Both the firſt and ſecond ſpecies are adapted to the large borders of pleaſure-grounds, where they have a good effect in mixture with others of a ſimilar growth; but the firſt is ſometimes troubleſome as a weed. The other kinds, from the beauty of their flowers, produce a pleaſing variety in aſſemblage with other potted annual plants.

DATURA *Stramonium*, in the *Materia Medica*. The whole of this plant is powerfully narcotic and poiſonous. It was firſt introduced into medicine by Dr. Stoerck, and employed by him in ſeveral caſes of mania with ſucceſs. It is occaſionally employed in epileptic and other convulſive diſorders, ſometimes with obvious advantage. The preparation commonly uſed is the inſpiſſated juice, of which, if recent and well prepared, the firſt doſe ſhould be not more than a quarter of a grain, which may be ſlowly increaſed till it produces ſome degree of vertigo, headach, and difficulty of ſwallowing. A remarkable degree of dilatation of the pupils and inſenſibility to light alſo attend the uſe of this powerful remedy, on which account ſome have ſuggeſted to employ it as a preparative to operations on the eye, where fixity and dilatation of the pupils are deſirable; but we do not know whether this has actually been put in practice.

DAVA, or USPO, in *Geography*, a province of Japan.

DAVACA TERRÆ, a portion of land in Scotland, ſo called; et apud priſcos Scotos, dawach of land, quod continent quatuor aratra terræ, quorum unum quodque trahitur octo bobus.

DAVALLIA, in *Botany*, a genus of dorſiferous ferns, named by Dr. Smith in the Memoirs of the Turin Academy, in honour of Mr. Edmund Davall, F. L. S. late of Orbe, in Switzerland, a moſt acute and intelligent botaniſt, whoſe illuſtrations of Swiſs plants, though left at his death, in 1798, in an incomplete ſtate, may one day be found worthy of being communicated to the public. Sm. in Mem. de l'Acad. de Turin, v. 5. 414. t. 9. f. 6. Tracts, 245, t. 1. f. 6. Swartz, Fil. 130. Claſs and order, *cryptogamia filices*: ſect. *Annulatæ*. Nat. Ord. *Filices dorſiferæ*.

Eſſ. Ch. *Capſules* in roundiſh, ſeparate dots, near the margin. *Cover* like a ſcale, from the ſurface, diſtinct, ſeparating outwards, terminating a vein.

The habit of this genus is firm, poliſhed, and compact, not tender, membranous, and expanſive like a *trichomanes* or *adiantum*. The *involucrum* or cover is often lunate, always ſolitary, at each round congeries of capſules, and each capſule is embraced by a genuine, diſtinct, jointed ring.

Sp. 1. D. *heterophylla*. Sm. Tracts, 250. Sw. Fil. 130. (Humata ophioglоſſa; Cavan. Leccion, 273). Barren fronds ovate, acute, undivided, entire; fertile ones linear-lanceolate, ſinuated, many-flowered. Found in Sumatra, and alſo in the Nicobar, and Ladrone iſlands. *Roots* creeping, branched, round, ſcaly. *Fronds* about half an inch or an inch aſunder; the barren ones on ſhort ſtalks, ſimple, ovate, acute, undivided, entire, ſmooth, about an inch and a half long, with a midrib and many fine veins; fertile ones above twice as long, but narrower, ſinuated like the leaf of a *pedicularis*, each lobe bearing ſeveral ſpots of fructification, every one of which is concealed by its own kidney-ſhaped *cover*. 2. D. *pinnatifida*.

Sw. Fil. 130. (Humata pinnatifida; Cav. Lecc. 273). Barren fronds ovato-lanceolate, acute, undivided, entire; fertile ones lanceolate, pinnatifid. *Cav.* Gathered by Louis Née in the Ladrone iſlands. We know it only from Cavanilles's deſcription. The barren *fronds* are ſaid to be more than two inches long, the fertile ones much longer, with linear ſegments. 3. D. *pectinata*, Sm. Tracts, 249. Frond lanceolate, pinnatifid, pectinated; ſegments obtuſe, undulated, many-flowered; the lowermoſt auricled, or half pinnatifid. A native of Malacca, the Nicobar iſlands, and Otaheite. Its ſize and habit reſemble *polypodium vulgare*, but the great number and horizontal regularity of the ſegments, which are very deep, approach, though imperfectly, to the beautiful *polypodium criſpum, ſtruthionis pennam referens*, Plum. Fil. t. 82. which Linnæus confounds with his P. *ſtruthionis*. Each lobe is furniſhed with a double row of fructifications, eſpecially in the upper parts. The *covers* are ſemicircular. The loweſt lobes of each frond are always more or leſs auricled on the lower ſide at the baſe; ſometimes they, and ſome of the next, are deeply pinnatifid. 4. D. *contigua*, Hedw. Fil. faſc. 4. Sw. Fil. 130. (Trichomanes contiguum; Forſt. Prod. 84.) Frond linear-lanceolate, pinnatifid; ſegments linear, obtuſe, ſomewhat cut. Sw. A native of the iſlands of the Pacific ocean, of which we have ſeen no ſpecimens. 5. D. *pinnata*. Cav. Lecc. 277. Frond pinnate. Leaflets linear, alternate, crenate. Stalk triangular. Cav. Found by Louis Née in Chili, as well as in the Philippine iſlands. The *ſtalk* is triangular with a longitudinal furrow, reaching to the ſummit of the plant. *Leaf* a foot long, compoſed of alternate, undulated leaflets, ſix inches long, and two lines broad, but narrower towards the point. Near every inciſion are one or two globoſe dots of fructification, each with a cup-like *cover*, which is not ſo long as broad, and adheres to the leaf by its baſe and ſides. Cav. 6. D. *falcata*. Sm. Tracts, 249. Sw. Fil. 13? Frond pinnate. Leaflets lanceolate, ſomewhat ſickle-ſhaped, undulated, many-flowered, unequally heart-ſhaped at the baſe. In the Linnæan Herbarium, but from what country is unknown. The *frond* is long and narrow. *Leaflets* very numerous, alternate, crowded, ſeſſile, about an inch long, lanceolate, bluntiſh, wavy, ſomewhat curved upwards. *Dots* numerous, each with a ſemicircular flat *cover*. Plumier's tab. 63. ſeems to be a different plant, and probably an *aſpidium*. 7. D. *pedata*. Sm. Tracts, 248. (Adiantum repens; Linn. Suppl. 446. Humata trifoliata; Cav. Lecc. 273. according to Swartz.) Frond with five angles, three-cleft and pinnatifid; the end of its ſegments crowded with fructifications. A native of the Mauritius, and of the Ladrone iſlands. *Root* long, creeping, and ſcaly. *Fronds* on upright ſcaly ſtalks, two or three inches long, each frond with five unequal angles, and compoſed of three, more or leſs diſtinct, leaflets, which are thick, poliſhed, ſtriated beneath; the central one moſt pinnatifid and acute. *Dots* ſmall, crowded near the points of the lobes, and each with a rounded cloſe cover. 8. D. *hirſuta*. Sw. Fil. 131. (Trichomanes hirſutum. Thunb. Jap. 339; but not of Linnæus.) Frond bipinnate, hairy. Leaflets confluent, lanceolate, ſickle-ſhaped, crenate on the upper edge. Sw. Grows in Japan. *Frond* with its ſtalk clothed all over with very ſhort denſe hairs; doubly pinnatifid, and a ſpan long. *Leaflets* alternate, lanceolate, bluntiſh, gradually ſhorter upwards, pinnatifid; their lobes lanceolate, crenate. *Dots* ſolitary in each notch. Thunberg. 9. D. *adiantoides*. Sw. Fil. 131. (D. domingenſis; Spreng. Sw. Filix arboreſcens adiantoides major; Plum. Fil. 7. t. 6.) Frond doubly compound. Leaflets lanceolate, pointed, pinnatifid, crenate. Dots round, almoſt marginal, with a cup-ſhaped cover. A native of Hiſpaniola and Jamaica. A beautiful fern, whoſe *leaflets* are ſometimes variouſly pinnatifid, the lobes being occaſionally rounded and ſhort, as in Plumier's figure, and at other times elongated and acute, on the ſame leaflet. The *dots* are numerous, ſo near the edge as to approach the character of a *Dickſonia*, but their *cover* is truly ſolitary, ſhort, broad, and very thin, ſeeming never to combine with any reflexed marginal cover. 10. D. *piloſiuſcula*. Frond thrice compound, pointed. Leaflets ovate, blunt, decurrent, crenate, hairy. Dots ſcattered, globoſe. Cover crenate. Sm. MSS. Communicated by the late Mr. Chriſtopher Smith from Honimoa and Amboyna. *Frond* large and ſpreading, rough in every part with ſhort tawny hairs, thrice compounded in an alternate order; the principal diviſions taper-pointed; the ultimate ones ovate, blunt, crenate. *Dots* ſparingly ſcattered, at ſome diſtance from the edge of the leaves, ſmall, yellowiſh, globoſe, each inveſted with a turgid, membraneous, pale brown or yellowiſh, cup-ſhaped, crenate cover. 11. D. *elata*. Sw. Fil. 131. (Trichomanes elatum; Forſt. Prod. 85. Wibelia elata; Bernhardi in Schrad. Journ. for 1801, 122. t. i. f. 2.) Frond thrice compound, pointed. Leaflets lanceolate, pinnatifid, cut, crowded, ſtraight; their ſegments with two teeth. Covers elliptic-oblong, ſhorter than the teeth. Found in the South-Sea iſlands. The *frond* is tall, repeatedly compounded, ſmooth, its ultimate leaflets crowded, ſmall, lanceolate, acute, many-ribbed, toothed; each tooth as it were cloven to lodge a dot of fructification, whoſe cover is elliptic-oblong, entire, not reaching to the points of the teeth. 12. D. *ſolida*. Sw. Fil. 132. (D. procera; Hedw. Fil. faſc. 4. according to Swartz. Trichomanes ſolidum; Forſt. Prod. 86.) Frond thrice compound, rhomboid. Leaflets ovate, auricled at the upper edge, notched. Dots ovate, not reaching to the notches. Covers abrupt. A native of the South-Sea iſlands, and of New Holland near Port Jackſon. *Root* clothed with very ſoft, narrow, curling ſcales. *Frond* near two feet high, ſmooth, firm, not poliſhed, alternately tripinnate, acute; its whole form, and chief diviſions, ſomewhat rhomboid. *Leaflets* much inclined to be dilated or auricled at their upper edge at the baſe: ultimate ones ovate or elliptical, bluntiſh, ſtrongly, but ſimply, notched or toothed. *Dots* ſolitary in each tooth, not reaching to the edge, ovate or urn-ſhaped, at length reddiſh, each with a cloſe *cover* of the ſame form, abrupt, but in ſome degree dilated and plaited at the extremity. Probably Rumphius's *Dryopteris arborea*, v. 6. t. 32. f. 1. may, as Dr. Swartz ſuſpects, be this plant; at leaſt we know none more like it. 13. D. *elegans*. Sw. Fil. 132. (Trichomanes denticulatum; Houtt. N. h. v. 2. t. 100. f. 2. Sw.) Frond thrice compound, lax, taper-pointed. Leaflets lanceolate, cut, ſerrated; each ſerrature double-toothed, embracing a ſolitary round dot. Brought by the late ſir G. L. Staunton from China. The *frond* has a lax and ſeemingly drooping habit, with a dark-green hue and poliſhed ſurface. *Leaflets* and their ſegments elongated; the latter lanceolate, decurrent, acute, ſtriated, ſerrated, each ſerrature formed of two forceps-like connivent teeth, between which ſtands the round *dot* of fructification, with a brown, orbicular, though ſomewhat abrupt *cover*, reaching to the edge of the leaf betwixt the teeth. We have a *Davallia* gathered by the late Mr. Chriſtopher Smith, on Barn iſland, in the ſtraits of Sincapore, which ſeems a variety of this with leſs connivent teeth, and not quite ſo lax a habit. Mr. Menzies alſo gathered one very like it, if not the ſame, in Otaheite. 14. D. *patens*. Sw. Fil. 132. Frond thrice compound; its diviſions nearly oppoſite, ſpreading. Leaflets lanceolate, pinnatifid; their ſegments linear, tipped with fructification, which

which extends rather beyond their points. Mentioned by Swartz as a native of the Eaſt Indies. We have met with nothing that preciſely anſwers to his deſcription, though Mr. Menzies found in Otaheite a ſpecies which comes very near it. 15. D. *pyxidata.* Cav. Leccion. 278. Frond thrice compound. Leaflets ſtalked, ſomewhat rhomboid, pinnatifid, or cut; their lower lobes unequal; their margins notched. Dots marginal, each ſurmounted by a blunt tooth. A native of the iſle of Luçon, and of New South Wales, near Port Jackſon. *Root* creeping, long, and very ſcaly. *Stalks* two to ſix inches high, ſmooth. *Frond* firm and ſmooth, ſix to twelve inches long, and half as broad at the wideſt part. The firſt, ſecond, and ſometimes third ſubdiviſions are alternate and ſtalked; the laſt elliptical, inclining to rhomboid, pinnatifid or cut, crenate, their lower lobes unequal in ſize. *Dots* ſolitary in each notch, reaching to its edge, but ſurmounted by its blunt incurved tooth. *Cover* reddiſh, ſomewhat urn-ſhaped and turgid; its margin rounded and wavy. 16. D. *caudata.* Cav. Leccion. 279. Frond twice or thrice compound, ſhining, taper-pointed. Leaflets ſtalked. Fructifications oblong. Cav. Diſcovered by Louis Née at the Philippine iſlands. Cavanilles, from whom alone we have any knowledge of this ſpecies, deſcribes it as much larger than the laſt, ſhining, as well as ſmooth, on the upper ſurface, doubly and alternately pinnate. The primary diviſions are eight inches long, two wide, with a terminal waved point, an inch and half long, ſcarcely a line broad. The ſubdiviſions are from one and a half to four inches in length, lanceolate, pinnatifid; wedge-ſhaped at the baſe. About the margin of each ſegment are three or four *dots* of fructification, larger than in the preceding ſpecies. 17. D. *cuneiformis.* Sw. Fil. 133. (D. didyma; Hedw. Fil. faſc. 4. Trichomanes cuneiforme. Forſt. Prod. 85; according to Swartz.) Frond thrice compound. Segments wedge-ſhaped, ſomewhat ovate, cut. Dots in pairs. Sw. Found in the South-Sea iſlands. 18. D. *ſetoſa.* Frond thrice compound, all over hairy. Leaflets alternate, decurrent, oblong, ſinuated. Dots ſolitary in each ſinus, briſtly. Sm. MSS. Found by Mr. A. Menzies in the Sandwich iſlands. The *frond* is perhaps two or three feet high, triply winged in an alternate order; the *leaflets* eſpecially are very regularly alternate, decurrent, oblong, bluntiſh, ſinuated ſo as to be almoſt pinnatifid. The *ſtalks* and whole *frond* are clothed with fine, briſtly, or ſhaggy, pellucid, jointed hairs. *Dots* ſolitary near each ſinus of the leaflets, round, brown, their *covers* concealed or clothed with numerous hairs like thoſe of the frond. 19. D. *aculeata.* Sw. Fil. 134. (Adiantum aculeatum; Linn. Sp. Pl. 1559. Filix ramoſa major, caule ſpinoſo, foliis ſeu pinnulis rotundis profundè laciniatis, ſeu cerefolii foliis; Sloane Jam. v. 1. 99. t. 61.) Frond thrice compound. Leaflets wedge-ſhaped, lobed, obtuſe, flat. Stalks zig-zag, with hooked prickles. Obſerved by Sloane, Swartz, and others, in Jamaica and Hiſpaniola. *Fronds* three or four feet high, triply winged, in an alternate order. *Stalks* ſlender, zig-zag, round, ſhining, beſet with little, ſcattered, hooked prickles. *Leaflets* ſmooth, alternate, divaricated, wedge-ſhaped, cut into two or three obtuſe, wedge-ſhaped lobes, at the extremity of each of which are lodged commonly two round *dots* of fructification, ſeemingly imbedded between the coats of the leaf, each with its own ſmall *cover* diſtinct from thoſe coats. 20. D. *dumoſa.* Sw. Fil. 135. (Adiantum fruteſcens, ſpinoſum et repens; Plum. Fil. 77. t. 94.) Fronds thrice compound. Leaflets wedge-ſhaped, lobed, abrupt; their extremities reflexed. Prickles of the ſtalks ſtraight. Plumier, and long ſince his time Thierry, have gathered this fern in Hiſpaniola. Linnæus confounded it with the preceding; and indeed it is difficult to ſay which he intended by his *Adiantum aculeatum*, neither of them being in his Herbarium. As the former is the moſt common and beſt known, we follow Dr. Swartz in conſidering it as the original ſpecies. The preſent plant is ſaid to creep to a great extent, not only along the ground, but over the trunks of trees, its *fronds* being very long, and ſo covered with ſpines that Plumier obſerves it looks more like a bramble than a fern. Theſe ſpines are not only vaſtly more numerous, and larger, than thoſe of the foregoing, but ſtraight, not hooked, and the principal ſtalks at leaſt are leſs zig-zag. *Leaflets* abrupt, not rounded at their extremities; and reflexed at the edge, not flat. *Dots* ſmall, covered by the reflexed edge of the leaf. 21. D. *fumarioides.* Sw. Fil. 135. (Acroſtichum aculeatum; Linn. Sp. Pl. 1530. Trichomanes aculeatum; Sw. Prod. 137. Davallia aculeata; Hedw. Fil. faſc. 4., according to Swartz.) Frond thrice compound. Leaflets wedge-ſhaped, deeply cut into linear ſegments. Dots ſolitary. Prickles of the ſtalks hooked. Dr. Swartz and the younger Hedwig have moſt happily determined the genus of this fern, which was altogether miſplaced in *Acroſtichum*, and which is cloſely related to the two laſt ſpecies. Linnæus very negligently quotes the ſame ſynonym of Sloane for this and his *Adiantum aculeatum.* Both are natives of Jamaica. The name *fumarioides*, though a jumble of Latin and Greek too uſual among botaniſts, admirably expreſſes the habit of this delicate fern, whoſe foliage recalls the idea of our *Fumaria capreolata.* The deflexed hooks of the ſtalks diſtinguiſh it from the laſt, and more reſemble D. *aculeata*, but the narrow, linear ſegments of the leaflets, with one *dot* of ſeed-veſſels only near the point of each, make it evidently and ſufficiently diſtinct from both. 22. D. *canarienſis.* Sm. Tracts, 246. (Trichomanes canarienſe; Linn. Sp. Pl. 1562. Jacq. Ic. Rar. v. 1. 200. Polypodium luſitanicum; Linn. Sp. Pl. 1556.) Frond thrice compound, with three principal branches. Ultimate ſegments lanceolate. Dots ſolitary. A native of Portugal, the Canary iſlands, and the country about Algiers, where, as we are informed by M. Durand, it grows on the cork tree. It is frequent in our green-houſes, being cultivated with little trouble in a pot, and almoſt always covered with fructification. The appearance of the thick rough bare roots has given it the name of hare's-foot fern. The evident abſurdity of confounding this with the genus *Trichomanes*, both on account of its habit and character, firſt led the writer of this article to conſider the genera of this tribe, and to attempt a new method of diſtinguiſhing them, by the cover of their fructification, which has ſince been univerſally adopted and carried by various writers to great perfection. The *fronds* of this ſpecies are about a foot high, almoſt as broad as long, being divided into three principal branches, and thoſe twice or thrice pinnate; the ultimate ſegments are lanceolate, ſomewhat elliptical, entire, ſuch as bear fruit dilated and cloven. *Dots* ſolitary, round, orange-coloured. *Cover* cup-ſhaped, more or leſs crenate. 23. D. *retuſa.* Cav. Leccion. 278. Sw. Fil. 133. Frond thrice compound, broadeſt at the baſe. Branches tapering. Leaflets alternate, wedge-ſhaped, in two or three ſegments, abrupt. Dots in pairs or ſolitary. Cavanilles received this ſpecies from the iſland of Luçon. We have a ſpecimen gathered by Mr. Menzies in the Sandwich iſlands, which agrees ſo exactly with his deſcription that we have no doubt of its being the ſame. The *frond* is above three feet high, ſmooth in every part, its general outline oblong, pointed, broadeſt at the baſe, the firſt pair of *pinnæ* being the longeſt. *Stalk* and *branches* round; the latter obſcurely bordered or winged. All the *pinnæ* and *leaflets* are alternate; the latter wedge-ſhaped, narrow, entire

tire at the ſides, ſtriated, tapering down into a flattiſh ſtalk; their termination very abrupt, deeply ſplit into two or three lobes unequal in length, often with a minute point at each terminal angle. *Dots* one or two at the ſummit of each lobe, ſmall. *Cover* broad, ſhort, wavy. 24. D. *microcarpa*. Frond thrice compound, lanceolate. Leaflets alternate, wedge-ſhaped, in two or three ſomewhat elliptical ſegments, abrupt. Dots in pairs, or ſolitary, minute. Sent us by the late Mr. Chriſt. Smith from Amboyna. The whole *frond* is rather ſmaller than the laſt, and lanceolate, the *pinnæ* about the middle part being the longeſt; theſe, as well as the lower ones, are nearly oppoſite; but this may be a variable circumſtance. The ſegments of the *leaflets* differ materially from the laſt in being ſomewhat elliptical, and rather contracted at the extremity, which ſtrikes the eye at firſt ſight. The *dots*, conforming to this contraction, are very ſmall and ſhort. We cannot refer this to any ſpecies deſcribed by Swartz or Cavanilles, though it is unqueſtionably allied to ſome of the following. 25. D. *chinenſis*. Sm. Tracts, 247. Sw. Fil. 133. (D. ferruginea; Cav. Leccion, 277? Adiantum chuſanum; Linn. Sp. Pl. 1558. A. tenuifolium. La Marck Encycl. v. 1. 44. A. nigrum chinenſe, tenuitèr diviſum, pinnulis minimis obtuſis plerumque bifidis; Pluk. Phyt. t. 4. f. 1. Trichomanes chinenſe; Linn. Sp. Pl. 1562. Oſb. It. 242. t. 6?) Frond thrice compound, lanceolate. Leaflets alternate, wedge-ſhaped, in two or three ſegments, abrupt, jagged. Dots in pairs, or ſolitary, roundiſh. A native of China. *Root* tufted with a few branched ſomewhat hairy fibres. *Stalk* ſmooth, channelled in front with obtuſe edges. *Frond* about a foot high, in texture and colour like D. *canarienſis*, but lanceolate as in the laſt ſpecies, alternately thrice-pinnate. *Leaflets* wedge-ſhaped, cloven, or three-cleft, rather dilated than contracted at the extremity, which is externally jagged or toothed. *Dots* ſolitary, or in pairs, large, roundiſh. *Cover* pale, wavy, cup-ſhaped. Such is the original ſpecimen which Linnæus appears to have deſcribed twice over. The figure of Oſbeck repreſents the leaflets too much dilated and rounded, and yet it is difficult to ſuppoſe his plant different from that of Linnæus, who quotes him for the ſpecimen he deſcribed, which is intermediate in the form of its leaflets between the plates of Oſbecks and Plukenet. Cavanilles's deſcription of his *Davallia ferruginea* ſo well accords with our plant, that we cannot believe them to be different, and he himſelf preſumed either that or his *retuſa* muſt be the Linnæan *Trichomanes chinenſe*. We thus reduce three ſpecies of Dr. Swartz to one. 26. D. *gilberoſa*. Sw. Fil. 134. (D. glauceſcens; Hedw. Fil. Faſc. 4. Trichomanes gibberoſum; Forſt. Prod. 85.) Frond thrice compound, glaucous beneath. Segments of the leaflets linear, entire, gibbous, obtuſe, bearing fructification at their inner margin. A native of the South-Sea iſlands, known to us only by the ſhort characters given by Forſter and Swartz. We ſhould have ſuppoſed it a *Darea* but for the authority of the latter. 27. D. *epiphylla*. Sw. Fil. 134. (Trichomanes epiphyllum; Forſt. Prod. 85.) Frond thrice compound, taper-pointed. Leaflets deeply ſerrated and cut. Dots below the points of the ſegments. A native of the South-Sea iſlands, which we have adopted, like the laſt, from Swartz and Forſter. The latter deſcribes the fructifications as ſeated on the upper ſide of the frond, which is contrary to all example, and, from the learned Swartz's ſilence, probably a miſtake. 28. D. *glauca*. Cav. Leccion. 278. Sw. Fil. 134. Frond thrice compound, glaucous. Leaflets linear, pinnatifid, acute, alternate. Dots ſolitary, globoſe. Gathered by Louis Née, in that part of the Andes called the *Cordillera del Planchon*. Cavanilles, from whom alone we have any knowledge of this ſpecies, deſcribes it as follows. "The plant, at firſt ſight, appears like the *Trichomanes tamariſciforme*, deſcribed and figured by Jacquin, in the third volume of his Collectanea, 285. t. 21. f. 2. but is not very different from it. Our plant, without including the *ſtalk*, which is ſmooth, and marked with a longitudinal groove, is more than a foot high, by four inches in breadth. It is all over of a pale hue, and thrice pinnate, in an alternate order. The *leaflets* are linear, pinnatifid, from one to three lines long, with ſharp taper points. Each of them bears, very near the edge, a ſolitary globoſe *dot* of fructification like the point of a pin." 29. D. *clavata*. Sm. Tracts, 247. (Adiantum clavatum; Linn. Sp. Pl. 1559. A. minus, foliis in ſummitate retuſis; Plum. Fil. 75. t. 101. f. *b*.) Frond upright, alternately thrice compound. Leaflets linear, club-ſhaped, ribbed. Dots ſolitary, terminal, broader than the barren part of the leaflet. A native of the Weſt Indies. *Frond* about a foot high, with a long, ſmooth, pale ſtalk; divided into ſeveral alternate principal branches, each of which is once or twice, likewiſe alternately, pinnate. *Leaflets* alternate, undivided, half an inch long, ribbed, wedge-ſhaped, but extremely narrow, except at the very ſummit, where they are dilated to receive the *dots* of fructification, which are ſolitary, tranſverſely elliptical, with a toothed *cover*. The apex of the leaflet is alſo ſimilarly toothed and abrupt. Linnæus, at one time, confounded this with a very different fern, his *Trichomanes capillaceum*. Plum. Fil. t. 99. f. D, but it does not appear that he has any where deſcribed it as ſuch. 30. D? *trifoliata*. Sw. Fil. 133. (Adiantum trifoliatum; Linn. Sp. Pl. 1558. A. triphyllum et retuſum; Plum. Fil. 81. t. 99. f. B.) Frond pendulous, zig-zag, alternately twice compound. Leaflets ternate, linear-wedge-ſhaped. Dots ſolitary, terminal. Plumier mentions this as growing in the clefts of trees, but in what particular iſland of the Weſt Indies he does not ſpecify. Swartz mentions Hiſpaniola, yet the plant does not occur in his Prodromus. We preſume, therefore, he adopted it from Plumier, and that the latter only has ſeen it. He deſcribes it as of a moſt beautiful green, with very ſlender, black, creeping roots. *Stalks* black, ſlender, branched, zig-zag. *Leaflets* ternate from each flexure of the branches, four lines long, of a very narrow wedge-like form, blunt, the extremity "bent back ſo as to cover a little collection of fine duſt." Now, if this deſcription be correct, and it is all we have to guide us, the plant is an *Adiantum* (ſee ADIANTUM, ſp. 21.); and yet Dr. Swartz ſays, "it appears rather to belong to *Davallia* than to *Adiantum*," an obſervation to which we ſhould pay the higheſt deference, and ſuppoſe Plumier to be incorrect, if Dr. Swartz had ſeen this ſpecies himſelf, which the mark of a croſs in his book implies he has not. We are, therefore, moſt inclined to believe this plant ought to remain in *Adiantum*, and we have mentioned it here chiefly to excite the attention of travelling botaniſts, and to preſerve, as much as poſſible, the knowledge of ſo pretty and curious a vegetable production.

Dr. Swartz ſuſpects that *Trichomanes capillaceum* of Linnæus, Plum. Fil. t. 99. f. D, alſo *Adiantum trilobum*. Linn. Plum. ibid. f. C, and f. A. tenuitèr diviſum, may all be *Davalliæ*, but we have not materials either to confirm or to refute this opinion. S.

DAVANA, in *Ancient Geography*, a town of Aſia, in Meſopotamia, ſeated on a plain at ſome diſtance N.E. from the river Billicha.

DAVARA, the name of a hill of Aſia Minor, towards mount Taurus. Tacitus.

DAUBA, in *Geography*, a town of Bohemia, in the

circle of Boleſlaw; 16 miles W.N.W. of Jung-Buntzel.

DAUBE, a ſmall town of Saxony, in the circle of Meiſſen or Miſnia, remarkable for a quarry of good mill-ſtones, which are ſent at great diſtances by the Elbe.

DAUBENSEE, a lake of Germany, in the circle of Bavaria; 10 miles S. of Traunſtein.—Alſo, a lake of Swiſſerland, on mount Gemmi.

DAUBING, in *Agriculture*, a term ſignifying plaſtering with clay, in the operations of ploughing, harrowing, &c.

DAUBY, a term applied to clayey land when wet, ſignifying clammy, or ſticky.

DAUBENTON, Lewis Mary, in *Biography*, doctor in medicine, member of the Royal Academy of Sciences at Paris, and of the Royal Societies of London and Berlin, was born at Montbard in Burgundy in 1716. Having taken his degree of doctor in medicine in 1740, he went to Paris, and his diſpoſition leading him particularly to the ſtudy of comparative anatomy, he was, through the influence of his countryman, the celebrated M. De Buffon, made keeper of the royal cabinet of natural hiſtory. In this ſituation he was enabled to contribute very largely to the ſplendid natural hiſtory, firſt publiſhed by M. De Buffon, in 1749, and which has been ſeveral times reprinted: every thing relating to the anatomy both of men and animals in that work being furniſhed by Daubenton. In 1784, he publiſhed at Paris, "Inſtructions for Shepherds and Proprietors of Flocks;" and in the ſame year "A methodical View of Minerals," with their diſtinctive characters, according to a new arrangement which he had contrived; he alſo communicated to the Academy of Sciences "Obſervations on the Liquor contained in the Allantois of Animals," on ſome "Teeth and Bones remarkable for their Size," and on the "Situation of the Foramen Magnum, in Men and in certain Animals." By good fortune, or by his prudence, he not only eſcaped being maſſacred during the revolution in France, but, in 1799, he was elected member of the conſervative ſenate. He died December, in the ſame year, in the the 84th year of his age, and was honoured with a funeral oration by the naturaliſt, Lacepede. Haller Bib. Anat. General Biography.

DAUCHITÆ, in *Ancient Geography*, a people of interior Libya.

DAUCIONES, a people of Scandinavia.

DAUCUS, *in Botany*. Carrot, (Δαυκος; Dioſc.) Linn. Gen. 131. Schreb. 182. Willd. Sp. Pl. v 1. 1389. Juſſ. 224. Gærtn. t 20. Claſs and order, *pentandria digynia*. Nat. Ord. *Umbelliferæ* or *Umbellatæ*.

Gen. Ch. *Umbel* compound; concave when in fruit. *Involucrum* of ſeveral pinnatifid leaves. *Cal* ſuperior, obſolete. *Cor.* Petals five, inverſely heart-ſhaped, inflexed; the outer ones larger and radiant. *Stam.* Filaments five, capillary, ſpreading; anthers roundiſh. *Piſt.* Germen inferior, ſmall, elliptical, compreſſed, rough; ſtyles two, reflexed; ſtigmas blunt. *Peric.* none. *Fruit* ovate, hiſpid. *Seeds* two, elliptic-oblong. Central flowers of each umbel abortive.

Eſſ. Ch. Involucrum pinnatifid. Corolla ſomewhat radiant. Fruit muricated. Central flowers abortive.

D. *Carota*. Common Carrot, Engl. Bot. t. 1174. Woodv. Med. Bot. t. 161. Mart. Ruſt. t. 82. is biennial, frequent in a wild ſtate about the borders of fields, and univerſally cultivated for its eſculent root. The leaves are finely divided and ſubdivided. Stem furrowed, hiſpid, branched. Flowers white, numerous, the central one only in each umbel being of a more or leſs deep blood-red, and abortive. D. *Gingidium* is a large broader-leaved ſpecies, found in the ſouth of Europe, from which D. *lucidus*, Linn. Suppl. 179, proves not to be different. D. *Viſnaga* of Linnæus, uſed in Spain for tooth-picks, is rather a ſpecies of *Ammi*. Several new ſpecies of *Daucus* are announced in the Prodromus Fl. Græcæ by Dr. Smith, and others may be found in Desfontaines' Flora Atlantica.

Daucus, in *Gardening*, comprehends a plant of the tap rooted eſculent kind; the common carrot (D. *Carota*).

Method of Culture.—In the culture of this uſeful vegetable, a deep light ſoil ſhould be employed as much as poſſible, and when of a ſandy quality it is ſtill more advantageous. It ſhould have been well manured the preceding year, as when it is applied the ſame year, the roots are apt to be affected with the canker. Where it is made uſe of the ſame year, it ſhould of courſe be well rotted, as ſuch as has been uſed in the hot bed in forcing cucumbers, melons, &c.

In preparing the ground, it ſhould be well trenched over, at no great length of time before the period of ſowing, to the full depth of eighteen inches; the lumps being well broken and reduced, and the manure when uſed at the time completely turned in. When this buſineſs is not performed in a perfect manner, the roots are liable to ſpread in a lateral direction, and become branched, and of but little value.

The ſituation ſhould be open, and free from the droppings of trees, or other inconveniences of the ſame kind.

The ſeed for this crop ſhould always be ſuch as has been collected from plants of the preceding year, and which is perfectly freſh and well ripened: as old ſeed never anſwers well in this culture, much of it being in a ſtate incapable of vegetating in a proper manner.

The ſorts moſt proper for the different garden crops, are for the early ones the horn carrot; but for the general crop, the orange is conſtantly to be employed, not only as growing more large, but more ſtraight and handſome, and keeping better, as well as being more ſweet and pleaſant to the taſte, when dreſſed for the table.

And the other varieties may be grown where variety is wanted. Whatever ſort is made uſe of, it is of much conſequence to have genuine ſeed.

As to the times of ſowing this ſort of crops, they muſt vary according as they are wanted. When they are required in ſucceſſion, three or four different ſowings ſhould be made from January till the beginning of May; but for the principal crop, the ſowings ſhould always be performed about the latter end of January, or in the beginning of the following month. A ſowing may likewiſe be made in Auguſt, to ſtand through the winter, for producing an early ſpring crop; or early crops of this ſort may be obtained by forcing them on hot-beds. The principal crop generally becomes ready for uſe about the beginning of June.

In the ſowing of the ſeed, after the ſurface of the bed has been rendered perfectly ſmooth and even by the rake, it ſhould be diſtributed in as even a manner as poſſible over the whole, and then carefully raked in. As the ſeed is of a light and chaffy nature, a calm dry time ſhould be choſen for the purpoſe, to prevent its being blown in an irregular manner into heaps. It is alſo uſeful to rub and ſeparate the chaffy parts of the ſeed well before ſowing, and ſome think it an advantage to have ſand or dry fine mould well mixed with it. It ſhould be ſown moderately thick, eſpecially when the ſoil inclines to be heavy. In very light ſoils it is ſometimes the practice to tread in the ſeed, to prevent its riſing in heaps, raking the ſurface over afterwards; but this ſhould never be done where there is any degree of ſtiffneſs in the land. The ſowings are uſually performed

formed on beds of four or five feet in breadth; but they may be made on large plats, where it is neceſſary to have a large ſpace of them.

After the plants have attained three or four inches in growth, they ſhould be thinned out from ſix to eight inches diſtance, in proportion to the ſize that is wanted; and be kept perfectly free from weeds: this is performed by a ſmall hoe with the greateſt readineſs; but ſome thin their plants out by the hand: the former is, however, the better method, as the earth is at the ſame time ſtirred about the roots of the plants. The work is beſt done when the weather is dry. The crops ſhould afterwards be occaſionally looked over every fortnight or three weeks, to be further thinned when neceſſary, and to keep the weeds from riſing in the ground.

Where theſe ſorts of roots are much wanted at an early period while young, it is better to ſow a piece of ground for the purpoſe, than to depend upon the thinnings of the general crops though theſe may often be thinned to advantage.

The crops which were put in, in Auguſt for the following ſpring produce, ſhould be managed in the ſame way; but it will be neceſſary to protect the plants, in winter, when the weather is ſevere, by coverings of ſome light dry materials, ſuch as litter, ſtraw, &c. ſo as to prevent their tops from being injured by the froſts.

Method of Culture on Hot-beds for early Uſe.—In this method of management, crops may be provided for early uſe, where thoſe of the autumn have been injured or deſtroyed by bad weather, or other cauſes.

In this intention, the ſowings ſhould be made in the beginning of January and the following month, on hot-beds formed of dung, moulded eight or ten inches deep, and covered by frames and glaſſes. In the growth of the plants, air muſt be freely admitted, by having the glaſſes removed, except in the night-time, and when the weather is ſevere. When the plants are an inch or two in height, they muſt be thinned out to the diſtance of three or four inches, and be occaſionally ſupplied with water in a moderate proportion. When the heat of the beds declines much, linings ſhould be had recourſe to as there may be occaſion, in order to keep them in a proper ſtate of growth.

By this management theſe roots may be provided a month or ſix weeks ſooner than in the other methods.

In order to preſerve the roots of the main crops in the winter, they ſhould be taken up about November, when the ſeaſon is dry; and when ſufficiently dried in the air, and cleared from earth, and their tops cut off cloſe, be packed up in dry ſand in a dry ſhed, cellar, or other convenient place, being well covered on the top with ſtraw. In this mode they may be preſerved till March or April. If they are ſuffered to remain in the ground, they are not only liable to be deſtroyed by vermin, but to become cankery, and rotten, and of courſe much loſs is ſuſtained.

And to ſave the ſeed of theſe plants, ſome of the fineſt roots ſhould be planted out about February, in rows two feet apart, and one foot diſtant from plant to plant. They will ſhoot up to ſtem in April or the following month, flower about June, and in Auguſt the ſeed becomes ripe; then the tops ſhould be cut off when dry, expoſed in the ſun, and after becoming perfectly dry, the ſeed thraſhed out, and put up into bags to be kept in a dry place for uſe. See CARROT.

DAUCUS CAROTA, in the *Materia Medica.* Carrots either boiled and maſhed to a pulp, or merely grated fine, form an excellent poultice to be applied, without the intervention of lint, to very foul ulcers particularly of the cancerous kind, which has a great and often truly ſurpriſing effect in abating the intolerable pain, and correcting the ſhocking fœtor that attends theſe dreadful diſorders.

DAUDIE, in *Geography*, a town of Egypt; 16 miles N. of Aſhmunein.

DAUE, or DAYE, in *Ancient Geography*, a town of Arabia. Steph. Byz.

D'AVELLA, GIOVANNI, in *Biography*, a friar who publiſhed at Rome in 1657, a work in folio, entitled, "Regole di Muſica," in five treatiſes, in which are promiſed "true and eaſy inſtructions for canto fermo, canto figurato, counterpoint, ſinging, and many other new and curious things," by Giovanni d'Avella, a friar, Rome, 1657. The ſplendid promiſes in the title-page are, however, as uſual, very incompletely fulfilled. The book is full of prejudices in favour of old rules, with many that are peculiar to the author; which render what was before dark and difficult, ſtill more unintelligible. From his ignorance of hiſtory, and the muſic of the ancients, he advances innumerable abſurdities, giving the Guidonian hand not only to Boethius, but to Plato and Ariſtotle; and tells us, that "Sr. Gregory ordered that no other gamut ſhould be uſed in the church, than that of Guido," who lived 500 years after him.

The account of this worthleſs publication is given as a beacon to eager collectors of old and curious treatiſes on muſic, in whom the title may increaſe "the rage of appropriation."

DAVENANT, JOHN, an Engliſh prelate of conſiderable learning, in the ſeventeenth century, was the ſon of a wealthy merchant, and born in London. He was admitted penſioner of Queen's college, Cambridge, in 1587. Here he took his degrees, and after the death of his father accepted a fellowſhip in the college. In 1609 he took his degree of doctor in divinity, and was ſhortly after appointed lady Margaret's profeſſor, and one of her preachers. In 1614 he was elected maſter of his college. He ranked ſo highly among Engliſh divines, that he was ſent with others, by James I. in the year 1618, to the ſynod of Dort, to ſit and give their votes in that ſynod. See DORT. Dr. Davenant returned from Holland in the ſpring of the following year, and was in 1621 nominated biſhop of Saliſbury. He continued high in court-favour during the remainder of James's reign; but in 1630-1, he incurred the diſpleaſure of Charles I. for maintaining the doctrine of predeſtination, in a ſermon preached before him at Whitehall. He was ſummoned to anſwer for his conduct, and expreſſed much contrition for the offence, declaring that he would at all future times conform himſelf, as readily as any other perſon, to the royal commands. By this conduct, which was truly diſgraceful to a man of talents, he eſcaped farther trouble, and was aſſured of a reconciliation, but was never afterwards admitted to court. He died of a conſumption, April 20th, 1641. He was characterized by his contemporaries for hoſpitality, kindneſs, and much meekneſs in his deportment. He publiſhed many works, but the principal was, "A Latin Expoſition of St. Paul's Epiſtle to the Coloſſians," in folio. This is the ſubſtance of lectures read by him as lady Margaret's profeſſor. At the ſynod of Dort, he inclined to the doctrine of univerſal redemption, maintaining the certainty of the ſalvation of a certain number of the elect, and that offers of pardon were ſent not only to all that ſhall repent and believe, but to all who heard the goſpel, and that all might, if they choſe, be ſaved. Dr. Davenant was buried in the cathedral at Saliſbury. Biog. Brit.

DAVENANT, WILLIAM, a poet in the reigns of Charles I. and II. was the ſon of a tavern-keeper at Oxford, in which city he was born in 1665. He ſtudied at Lincoln college, but his ſtay there was ſhort, and his firſt ſituation in

the world was page to the ducheſs of Richmond: from hence he removed to the family of Greville lord Brooke, who would probably have become a zealous patron to the poet, had he not been deprived of life by the hand of an aſſaſſin. Mr. Davenant had, however, made himſelf ſufficiently known to bring out a play, "Albovine," in the following year, 1629, with great ſucceſs. From that time he was admitted to the familiar acquaintance of the principal wits about court, among whom, for many years, he maintained a reſpectable ſtation. In 1637 he was elected poet-laureate, and his attachment to the king involved him in the troubles of that period. He was apprehended by the parliament for a ſerious charge, but contrived to elude the vigilance of his keepers, and eſcaped to France. On account of ſome ſervices done for the king, he was made a knight, in the year 1643. This honour was conferred at Glouceſter. He ſoon after went again to France, where he embraced the Roman Catholic religion. This procured him the confidence of the queen, who had ſought a refuge there, and who ſent Davenant to England, to perſuade the king to make his peace with parliament, by giving up the intereſts of the church of England. He was unſucceſsful, and was ſeverely reprimanded by his ſovereign. Upon his return to Paris, he began his heroic poem, entitled, "Gondibert;" but he ſoon quitted his retirement, and undertook the project of carrying out a colony from France to ſettle in Virginia. The ſhip, however, in which he embarked, was taken by an armed veſſel belonging to the Parliament, and ſir William Davenant was committed a cloſe priſoner to Cowes caſtle in the iſle of Wight. In this ſituation he compoſed a part of his "Gondibert;" but in October 1650 he was removed to London for trial by a high-commiſſion court. He eſcaped with his life, but was kept two years a priſoner in the tower. Upon his releaſe from confinement, he had recourſe to a public exhibition of entertainments, as a mean of extricating himſelf from the indigence into which he had fallen. Theſe entertainments, which were at firſt a mixture of declamation and muſic, led to the reſtoration of dramatic pieces; and early in the following reign ſir William Davenant was made patentee of the company which performed in Lincoln's Inn Fields. From this period he ſpent his time in comfort and reputation. He continued to write plays till his death, which happened April 7, 1668. The complete works of ſir William were publiſhed by his widow in 1675, and dedicated to the duke of York, afterwards James II. Theſe, with the exception of "Gondibert," are now forgotton. This is an unfiniſhed poem, entitled by the author an "heroic," though he meant to aſſimilate it to the epic poems of antiquity; but it differs from them in rejecting the interference of ſupernatural agents, and making it a mere narration of human events, conducted by human characters. Sir William Davenant may be regarded as one of our firſt lyric poets, as he furniſhed the court with more maſques, with incidental ſongs and plays, during the reign of Charles II. than any other of our dramatic writers. Biog. Brit.

Davenant, Charles, the eldeſt ſon of ſir William, was born in 1656. The firſt part of his education he had at Cheam in Surry; but he finiſhed his ſtudies at Baliol college, Oxford. He ſhewed an early inclination to dramatic compoſition, and at the age of nineteen brought a tragedy on the ſtage, entitled, "Circe," which was much approved. He very ſhortly after this turned his attention to the civil law, in which he obtained a doctor's degree from the univerſity of Cambridge. He had now attained to a ſufficient degree of conſequence to be returned a member of parliament for St. Ives in 1685, and about the ſame time was joined in a commiſſion with the maſter of the revels for the inſpection of the pieces to be brought on the ſtage. He obtained other poſts of emolument in king James's reign, but it was not till after the revolution that he commenced political writer, and called the attention of the public to many intereſting pieces on the trade and revenues of the country. In the following reign he was appointed to the poſt of inſpector-general of the exports and imports, the duties of which office he performed with diligence and accuracy. He died Nov. 6th, 1714. His works are numerous: they were collected and publiſhed in five volumes 8vo. in the year 1771, by ſir Charles Whitworth, to which is annexed a copious index. "Dr. Davenant," ſays ſir John Sinclair, "is certainly a moſt valuable political author, and, conſidering that the modern ſyſtem of politics, founded on a ſpirit of commerce, on public credit, on paper circulation, and on ſkill in finance, was then, in a manner, in its infancy, he undoubtedly was a writer whoſe progreſs was more advanced than could have been expected at that time. It appears from his works that he had acceſs to official information, from which he derived many advantages. He ſeems, however, to have depended too much upon political arithmetic, or the ſtrength of figures, which ought only to be reſorted to when the fact itſelf cannot be aſcertained, being only a ſuccedaneum, when better evidence cannot be procured. He was, unfortunately, alſo a party writer, and ſaw every thing in the manner the beſt calculated to promote the views and purpoſes of his political friends at the time. Every thing they did was right, while every action of their enemies was ill-intended and ruinous. He poſſeſſed a very conſiderable command of language, and is ſometimes too prolix; but, on the whole, there are certainly very few that can rival him as a political author." Biog. Brit.

DAVENTRY, in *Geography*, is a market-town in the hundred of Faroſley, and county of Northampton, England, ſeventy-three miles N.W. from London, containing, according to the returns under the late act of Parliament, 503 houſes, and 2582 inhabitants. It is an ancient town, ſtanding in an angle between the rivers Nen and Avon, which induced Mr. Pennant to derive the name from *Dwy avon tref, i. e. the town of two rivers;* thus making it of Britiſh origin; and from the Roman encampment called *Burrow-hill*, in the vicinity, the conjecture is highly probable. It is an incorporated borough, though it has not the privilege of ſending members to parliament. The corporation conſiſts of a bailiff, twelve burgeſſes, a recorder, town-clerk, two head-wardens, and twenty common-council men. The bailiff, while in office, and the following year, acts as a juſtice of the peace, and coroner of inqueſts. Of the corporation the bailiff, ex-bailiff, with the recorder, conſtitute a quorum, and can attach for all debts under the ſum of one hundred pounds; and in criminal caſes commit the accuſed to the county gaols. The quarterly-ſeſſions are held for the pariſh as a diſtinct diſtrict. The charter was granted in the reign of king John, and confirmed by queen Elizabeth. The manor, in the time of Edward the third, was granted to the celebrated John of Gaunt, and annexed to the duchy of Lancaſter. Some veſtiges of his palace ſtill remain near Daventry park, and are called Burnt-walls. A large building, now occupied by poor people, was once a priory, which was founded about the year 1090, by Hugh de Leyceſter, for monks of the Cluniac order. This was one of the monaſteries which led to the general downfall of monachiſm in England. It was diſſolved by the permiſſion of pope Clement VII. in the ſeventeenth year of king Henry VIII; and granted to cardinal Wolſey, towards the erection of his new colleges in Oxford aud Ipſwich; but, as Stow ſays, "with fatal ſucceſs to the principal actors." The revenues were valued at the

diſſolution at 236*l.* Out of this ſum, granted to Chriſt-church, Oxford, a perpetual curacy was endowed, which is always held by a ſtudent of that college. A free-ſchool was founded here in 1576 by William Parker. The learned John Wilkins, biſhop of Cheſter, author of "An Univerſal Language," and other valuable works, was born at this place in 1614.

Daventry has a large weekly market on Wedneſdays, and four annual fairs, *viz.* on Eaſter-Monday, June the 6th, Auguſt the 3d, October the 2d, and the 27th. A little to the eaſt of the town is an ancient encampment, called Burrow-hill. It is diſpoſed in an oval ſhape, and extends about three quarters of a mile in length, by one quarter in breadth. It is defended on one ſide by a double foſs and vallum, and in ſome places by three, four, and five. On the ſouth-eaſt ſide of the hill is another encampment, which contains about an acre of land, and is ſurrounded by a ſingle foſs and vallum. Though theſe works are evidently Roman, Mr. Pennant refers them to the Britons; and both he and Mr. Gale agree to fix here the Benavenna of the Itinerary. Bridge's Hiſtory of Northamptonſhire. Pennant's Journey from Cheſter to London.

DAUGHTERS, among the *Ancients*, were more frequently expoſed than ſons, as requiring greater charge to educate and ſettle them in the world. See EXPOSING *of Children*. Thoſe who had no legitimate ſons were obliged, by the Athenian laws, to leave their eſtates to their daughters, who were confined to marry their neareſt relations, otherwiſe to forfeit their inheritance; as we find to have been practiſed likewiſe among the Jews, many of whoſe laws ſeem to have been tranſcribed by Solon.

If an heireſs happened to be married before her father's death, this did not hinder the neareſt relation to claim the inheritance, and even to take the woman from her huſband; which is ſaid to have been a common caſe. Potter, Archæol. Græc. lib. iv. c. 15. tom. ii. p. 441. See SON.

The ſons and daughters of the king of England are called the ſons and daughters of England; becauſe all the ſubjects of England have a ſpecial intereſt in them. See PRINCE.

DAUHN, or DAUN, in *Geography*, a ſmall town of France, in the department of the Sarre, chief place of a canton in the diſtrict of Prum, 33 miles W. of Coblentz. It has but 320 inhabitants, and the canton in 41 communes reckons only a population of 4790 individuals.—Alſo, a town of Germany, in the circle of the Upper Rhine, called Thaun; 12 miles S. of Simmern.

DAVIANUM, in *Ancient Geography*, *Veine*, a town of Gaul, in the province called "Secunda Narbonnenſis." It was between Seleucus to the ſouth-weſt, and Vapincum towards the north-eaſt.

DAVID, in *Biography*, king of the Jews, in many reſpects an illuſtrious character of ancient times, was the youngeſt ſon of Jeſſe, of the tribe of Judah, and was born about 1085 years before Chriſt. When Saul by his miſconduct had forfeited the crown to which he had been elected, David, who had hitherto attended principally to the buſineſs of a paſtoral life, was ſingled out by providence to ſucceed him. But we muſt trace him in the early parts of his life. He was pointed out by Samuel as heir to the throne, long before he actually took upon him the duties of government; and we are informed that he was inſpired with thoſe qualities of body and mind, that prepared him for the delicate and difficult ſcenes through which he would be called to paſs. When Saul was ſinking into a ſtate of deſpondency brought on by his vice, and by diſobedience to the divine command, David, who was a proficient in muſic, was ſent for to ſoothe the anguiſh of his wounded mind by the ſounds of his harp. By the wiſdom and prudence of his conduct he gained the king's favour, and was made his armour-bearer; כלים נשא, bearer of the inſtruments or weapons, of which there were different ſorts, *viz.* the ſhield, the target and ſpear, bucklers and ſwords. David's being armour-bearer to Saul, implies no more than that he was conſtituted one of his guards. What particular duties attached to this office it would be difficult to aſcertain; they were, however, of ſo eaſy a nature as not to preclude him from attending again to his father's domeſtic concerns. A war breaking out between the Iſraelites and Philiſtines, in which, previouſly to the deciſive engagement that was expected, the champion Goliah challenged the braveſt of his foes to ſingle combat, David was allowed to accept the challenge, and Saul would have clothed him in his own armour, but he choſe to make uſe of no other weapons than his ſtaff and ſling, in the uſe of which, like the ſhepherds of his times, he was exceedingly expert. Thus accoutred he brought the proud Goliah to the ground by a ſtone which he threw from his ſling, and he inſtantly cut off his head and preſented it to Saul. The defeat of the Philiſtines was the conſequence of the death of their leader. This exploit recommended David ſo much to the king, that he reſolved to keep him near his own perſon, appointed him to many poſts of honour, and determined upon giving him his eldeſt daughter, after he had made ſome further trial of his prudence and valour. In this ſituation he acquired the friendſhip of Jonathan, Saul's eldeſt ſon, and much eſteem among the people. (1 Sam. xviii.) Saul began to be jealous of the reputation and influence which David had among all ranks of people; and at length jealouſy degenerated into fear and hatred. He reſolved to deſtroy him, and deviſed many methods for this purpoſe, but David eluded them all. The particular circumſtance that ſerved to excite the invincible jealouſy of Saul, and to induce his determination to deſtroy him, was the following: The Philiſtines had encamped in the territories of the tribe of Judah, not far from Jeruſalem; where Saul ſeems to have continued ſome time after the rout of their army, and where David received the firſt tokens of his favour. But as Saul was returning to his own city, accompanied by David, the women came out of all the cities of Iſrael, through which they paſſed, ſinging and dancing, to meet the king, with tabrets and other inſtruments of muſic to expreſs their joy; and ſinging alternately, one chorus chanted "Saul hath ſlain his thouſands;" and the other replied, "David hath ſlain his ten thouſands." This, though probably innocently intended, filled Saul with indignation and rage; and the preference thus given to David ſeems to have excited the firſt ſuſpicion, that David was the man deſignated by Samuel, when he aſſured him, that "the kingdom ſhould be given to a neighbour of his that was better than himſelf;" for Saul ſaid in his rage, "they have aſcribed to David ten thouſands, and to me they have aſcribed but thouſands; and what can he have more but the kingdom?" From this time to the very end of his life, Saul looked on David with a malignant eye, and watched every opportunity to deſtroy him. Of this he ſoon gave David two very convincing proofs; for the very next day after theſe acclamations of the women, Saul fell into one of his mad fits of melancholy, and, as we render the words, "propheſied in the midſt of the houſe," or, as the learned Dr. Chandler tranſlates the expreſſion for critical reaſons, which he aſſigns, "howled and grumbled" in his frenzy; and as David was playing, without the leaſt ſuſpicion of danger, to divert his melancholy, Saul in an inſtant threw at him a javelin, which he had in his hand, with a reſolution to ſtrike him dead to the wall. David happily eſcaped this danger, and ran out of the room; and upon his entering it a ſecond time, Saul

threw a dagger at him, which he alſo avoided, and immediately withdrew from the king's preſence. This double deliverance alarmed Saul, and he was more than ever afraid and ſuſpicious of David, becauſe he ſaw that he was under the peculiar protection of God, whilſt he found himſelf deſtitute of his direction and favour. For this reaſon he removed David from immediate attendance upon him, and gave him a regiment, which he well diſciplined, and headed on every occaſion where its ſervice was neceſſary. In this command he behaved with ſuch remarkable prudence and circumſpection, as that Saul could find no reaſon for complaint, which, though it heightened Saul's diſtruſt of, and malice againſt him, yet ſecured him the eſteem of all Iſrael and Judah; becauſe they found him a good commander, and ſucceſsful in all the expeditions in which he employed his troops.

Saul, being thus diſappointed by David's cautious and gallant behaviour, ſent for him, and treacherouſly propoſed to give his elder daughter Merab to be his wife; hoping, that by venturing on ſome dangerous expedition againſt the Philiſtines, in order the more effectually to merit the king's daughter, he would be ſome time or other cut off in an engagement by their hands. David received the propoſal with humility and gratitude; but Saul broke his promiſe, and otherwiſe diſpoſed of his daughter. However, he gave him his ſecond daughter, Michal, with a view "that ſhe might be a ſnare to him." The condition ſtipulated on the part of Saul was, "100 fore-ſkins of the Philiſtines." David accepted the offer, and, before the expiration of the time that had been fixed, produced double the number required. The Hebrews were in a perpetual ſtate of war with the Philiſtines during the whole reign of Saul: and the only juſt reaſons that could vindicate Saul in commanding, and David in executing his command, to cut off 100 Philiſtines, were either God's order, or their being at war with the Philiſtines, or the neceſſity of it to weaken their enemies, or the ſafety of their country, the ſecurity of their liberties, or ſuch like motives; and if theſe motives concurred to juſtify David in accepting the condition of becoming Saul's ſon-in-law, by bringing the hundred foreſkins, his cutting off more of them was a yet higher ſervice to the public; and ſo far from being any breach of the rules of religion or morality, was a proof of real patriotiſm and public ſpirit; highly merited the thanks of his king and country, and rendered him more worthy of the honour intended him;—his alliance with Saul by the marriage of his daughter. David, therefore, notwithſtanding what has been ſaid by Bayle, and other writers of inferior note, to the contrary, might ſtill be "the man after God's own heart," and approving himſelf ſuch in this very inſtance; for though "God is unalterable," and always requires that we ſhould "do juſtly and love mercy;" yet it does not appear that God hath any where fixed the exact number of enemies to be killed in an expedition; nor does he require that a general ſhould ſpare an implacable enemy, invading his country, deſtroying the inhabitants of it, and determined to ſubvert the religion and liberties of it, when he hath an opportunity of deſtroying him, and when ſuch deſtruction becomes neceſſary to the preſervation and ſafety of the public. In the caſe before us, David, by the deſtruction of theſe Philiſtines, does not ſeem to have acted contrary to the rules of religion and morality, if war, in ſelf-defence, be in any inſtance allowable; for the men he deſtroyed were the enemies of his country, in a ſtate of actual war with his prince and people; and, therefore, lawful prize wherever he could lay hold of them, and in every expedition in which he was employed to haraſs and deſtroy them.

David married Michal, who affectionately loved him, and Saul obſerved with regret and vexation, that God protected him; and thus his apprehenſions and dread of David were increaſed, and his hatred and malice towards him rendered ſtill more and more implacable. Soon after this, the Philiſtines renewed their hoſtilities againſt the Hebrews. David was in the action, and his prudence and bravery became ſo remarkable, that he was deemed ſuperior to all the commanders of Saul, and highly eſteemed for his military abilities and conduct. Whilſt David was gathering freſh laurels in a ſucceſsful expedition againſt the Philiſtines, Saul fell into a freſh frenzy of jealouſy and rage; and, as David was playing upon his harp, according to his uſual practice, for the kind purpoſe of diverting his melancholy, Saul threw a javelin with ſuch force at him, which, happily miſſing him, ſtuck faſt into the wall of the room where he was ſitting. David immediately fled, and retreated to his own houſe. Saul purſued him, and appointed his guards to watch him, and to prevent his eſcape; but by the artifice and aſſiſtance of his wife, he was reſcued from this danger, and got ſafe to Samuel at Ramah. As ſoon as Saul had heard of the place of his retreat, he diſpatched, at three ſeveral times, meſſengers to apprehend him; but they were deprived, in an extraordinary manner, of the diſpoſition and power to ſeize him. Saul himſelf haſtened to Ramah, with the purpoſe of apprehending David; but his reſolution was in a ſingular manner counteracted and over-ruled; and he himſelf delivered, as it were, into the power of Samuel, and David eſcaped unhurt. This incident in his hiſtory affords a noble evidence of the innocence and loyalty of Samuel and of David; and at the ſame time a pleaſing inſtance to a generous compaſſionate mind, of the care of Providence over perſecuted virtue, and of the impotence of human malice towards thoſe whom God is determined to preſerve. David availed himſelf of the opportunity that now offered itſelf of making his eſcape to Jonathan, and of engaging his interference with Saul in his favour, in which buſineſs he acted the part of a faithful friend; and in ſo doing, incurred the reſentment of his father. Upon taking his leave of Jonathan, David went to Nob, a city belonging to the prieſts, in his way to the Philiſtines, amongſt whom he intended to take refuge from the perſecutions of Saul. Having at this place recovered Goliah's ſword, he haſtened to Achiſh, king of Gath; whoſe hoſtile deſigns he counteracted, by feigning himſelf mad. It has been ſaid, by thoſe who have calumniated the character of David, that he intended to enter into a treaty of alliance with this Philiſtine prince againſt the Hebrews; but this charge is contradicted by the attendant circumſtances; for, as he fled to Achiſh, under the apprehenſion of being aſſaſſinated by the machinations of Saul, it is plain that he never manifeſted any deſign of engaging with him againſt his king and country, becauſe he was taken up as a ſpy, and then diſmiſſed as a madman. Being ordered immediately to leave the dominions of Achiſh, he made the beſt of his way out of the territories of the Philiſtines; and, in acknowledgment of his happy deliverance, he penned the 34th pſalm. Upon his coming from Gath to the tribe of Judah, he retired to the cave of Adullam; where he was joined by his brethren, and by many others who were in diſtreſs, or in debt, or diſcontented; and ſeveral other perſons of known reputation and valour. (1 Sam. xxii. 1, 2.) In this ſituation he was grievouſly diſtreſſed with thirſt; and in order to procure water for him, three of his worthies broke through the hoſt of the Philiſtines then encamped at Bethlehem, and brought it to David; but ſuch were his ſelf-denial and forbearance, that he declined drinking it, becauſe it had been obtained for him at the hazard of the lives of his friends. The cave

of

of Adullam has been repreſented by thoſe who have been diſpoſed to cenſure David's conduct, as a place of rendezvous for his followers, and he has been charged with rebellion againſt Saul. But thoſe who reſorted thither did it freely, and without ſolicitation on his part; nor does it appear that David took the advantage of this circumſtance for depriving Saul either of his life or crown. In this reſpect, Mr. Bayle himſelf has been conſtrained to do him juſtice. On this occaſion, David acted ſolely upon the principle of ſelf-preſervation and defence; he never oppoſed or diſturbed the quiet of Saul's government; he never ſolicited the tribes to join him during his life, or excited a ſpirit of diſcontent and rebellion, or popular commotions againſt him; he never entered into any conſpiracy to dethrone him; never attacked his army; never by force levied contributions upon his ſubjects to ſupport him; never joined the enemies of his country to invade it; never diſputed any of his reaſonable commands, but ſerved him faithfully whilſt he employed him; never deſerted him, or provided himſelf with guards, till forced to it by the unrelenting jealouſy and rage of his unhappy perſecutor; never took any advantage that occurred for ſeizing his perſon, or deſtroying him; but in his whole conduct, behaved with all the ſubmiſſion that became him as a dutiful ſon-in-law to his father, and a good ſubject to his prince. As a faithful ſubject, he had a natural right to protection, and to ſecure himſelf from the violence of a tyrant, by any juſt and prudent meaſures within his power. His own repeated and ſolemn proteſtations of innocence ought alſo to be admitted in his favour, more eſpecially when they are confirmed and juſtified by the teſtimony of Jonathan, and that of Saul himſelf, after his life was ſpared in the cave of Engedi. (1 Sam. xxiv. 17, 18, 19. See alſo ch. xxvi. 18. 21. 25.) From the cave and ſtrong hold of Adullam, David removed to the foreſt of Hareth, where he penned the admirable hymn recorded in the 63d pſalm.

Soon after the barbarous outrage committed by Saul upon the prieſts at Nob, under the charge of Doeg, for having harboured David, he was informed that the Philiſtines were beſieging Keilah, a city in the tribe of Judah; and having inquired of the Lord, whether he ſhould go and ſmite them, and obtaining an anſwer in the affirmative, he went thither with his men, fought with the Philiſtines, brought away their cattle, ſmote them with a great ſlaughter, and thus ſaved the city and its inhabitants. This brave and gallant action merits the higheſt commendation. "It was," as Grotius (in loc.) juſtly obſerves, "an inſtance of his great love to his country, who, though proſcribed as a rebel by the king, was ſo far from injuring his country, as that he ſerved it at the coſt of his enemies." So far was David from making any attempt to keep poſſeſſion of Keilah, that when Saul was coming againſt the city on his account, and with a view of ſeizing him as his prey, he departed to the wilderneſs of Ziph, where he concealed himſelf in the natural fortreſſes of the rocks and mountains of that deſert. Saul purſued him with a deſign of taking away his life; but he was preſerved from falling into his hands. Saul, however, was called off from the purſuit by the news of a freſh invaſion of his territories by the Philiſtines. Whilſt David was in the wilderneſs with his guards, he lay near the eſtate of Nabal, who had ſheep and goats in abundance. Inſtead of ſuffering his men to pilfer or forcibly to take away any part of Nabal's property, he reſpectfully entreated ſuch a ſupply as his circumſtances required. Nabal returned a churliſh and abuſive meſſage (1 Sam. xxiv.); ſuch as was likely to excite the juſt reſentment of David. Abigail, however, the wife of Nabal, interpoſed, and by her temper and prudence, diſarmed David of his anger, and prevented the retaliation which he was meditating. In ten days after this event Nabal ſickened and died, and Abigail ſometime after became David's wife. The intercourſe on this occaſion between David and Abigail was carried on in the moſt open and public manner, in the preſence of David's men and Abigail's ſervants, in the field where they met; and it was begun and concluded without interruption, or any private conference between them, as appears by the whole ſeries of the hiſtory, that could give them the leaſt opportunity for any criminal intercourſe. If we duly conſider the ſeveral circumſtances recited in this hiſtory, although David's paſſion and oath to deſtroy Nabal and his family are by no means to be vindicated; though the reſolution was cruel, and the oath a raſh and wicked one; yet it muſt be allowed that the provocation given him was of the higheſt nature, aggravated with the moſt outrageous circumſtances, and ſuch as no military man could help grievouſly reſenting. What man of honour and generoſity, what ſoldier at the head of his troops, what ſon-in-law of a king, and heir to his throne, would have tamely borne all this vile indignity, and unmerited calumny and abuſe? Would any partiſan, in our modern armies, put up with an affront and injury like this, and not retaliate it with a ſeverity equal to what David threatened? However, he was happily prevented from avenging himſelf according to his intention, by being brought to a juſt ſenſe of the raſhneſs and cruelty of his purpoſe, and not by any methods of wickedneſs and villainy; and nothing can be more unreaſonable than the ſuſpicion of Abigail's proſtituting herſelf to David; ſince the two expreſſions, that may have given riſe to it, are not poſſibly capable of any ſuch interpretation. The firſt, "Upon me let this iniquity be," is a form of ſpeech frequently uſed in deprecating a puniſhment which another deſerves, by transferring, as it were, the crime and puniſhment upon the perſon who pleads for the criminal. (2 Kings xiv. 9. Pſ. lv. 3. Iſ. liii. 6.) It argues a corrupt mind to pervert it to a criminal meaning; and it is obviouſly, and by the faireſt interpretation, no more than if ſhe had ſaid, "Rather let me ſuffer than him." As to the other expreſſion, "I have accepted thy perſon," (ſee Gen. xxix. 21. Job xlii. 9. Iſ. iii. 3. Prov. xviii. 5.) its meaning is; "I have accepted thy interpoſition for Nabal, and for thy ſake will not execute my intended revenge upon him."

After David had honourably diſmiſſed Nabal's wife and ſervants, he concealed himſelf in the hill Hachilah, before Jeſhimon, whither he was purſued by Saul with 3000 choſen men. David, accompanied by Abiſhai, viſited the camp of Saul in the dead of the night, and found him with Abner, and all the people round about him, faſt aſleep. Abiſhai was eager to diſpatch his enemy, but David repreſſed his ardour, and manifeſted on the occaſion the moſt glorious moderation and fortitude of mind. (1 Sam. xxvi.) Was ever reſolution more generous and loyal? One ſtroke would have fixed his mortal enemy dead on the ſpot, put an end to all his fears, and mounted him to a throne. And yet this hypocrite, this diſſembler, this rebel, traitor, bloody ambitious parricide, for theſe are the titles with which he hath been decorated, immediately ſtarts back at the propoſal of it, and the proſpect of a crown will not tempt him to a baſe, diſloyal, and impious action to obtain it. David merely ordered Abiſhai to take away the ſpear at the bolſter of Saul, and the cruiſe of water that ſtood by him, and to carry them off, as the proofs of Saul's danger, and of his own fidelity to him. The whole paſſage recording this part of the hiſtory of David and Saul, if it had been found any where but in the Bible, would have been read with pleaſure, and pointed out as worthy of admiration, for the many excellencies

that

that are contained in it. Notwithſtanding Saul's promiſe to David at Ziph that he would do him no more harm, yet knowing his implacable temper, and apprehending, that the ſpirit of jealouſy and rage would return on him, David lived in a ſtate of perpetual anxiety. He therefore retired with his followers to Achiſh, king of Gath, who gave him, his family and companions, a very friendly reception, and aſſigned to him the town of Ziklag, as a permanent property for himſelf and followers. Here David was joined by ſeveral mighty men of valour, who accompanied him in his invaſion of the Geſhurites, Gezrites, and Amalekites. David's conduct on this occaſion has been ſeverely cenſured, and alſo miſrepreſented by Bayle. In mitigation of the ſeverity exerciſed by David, it has been ſaid, that the Amalekites were the ancient enemies of the Jewiſh nation, doomed, many ages before this, to deſtruction by the God of Iſrael. David, therefore, might have pleaded a divine command for exterminating the reſtleſs and inveterate enemies of his country. After the expedition now mentioned was terminated, David returns to Achiſh, and upon being aſked where he made his incurſion? David anſwers, "Againſt the ſouth of Judah, &c." which reply Mr. Bayle charges with falſhood, calling it, not very liberally, "a lie." But the anſwer was literally true, but ambiguous; for all thoſe people dwelt on the ſouth of Judah, &c. David was now in a critical ſituation; and the greateſt and beſt caſuiſts have allowed, that ambiguous anſwers are not always criminal, but ſometimes juſtifiable, eſpecially in ſuch a ſituation. (See Grotius de J. B. et P. l. iii. c. 1. §. 10, and Gronovius's note on the paſſage, paragr. 1. note 74.) Of this ſentiment were Socrates, Plato, Xenophon, Cicero, the Stoics, Ariſtotle, Quinctilian and others mentioned by Grotius, (lib. v. c. 1. §. 9, page 3 and 4.)

David, having been afterwards preſſed into the Philiſtine camp and ſervice by Achiſh, was reduced to the greateſt ſtraits, and ſcarcely knew how to conduct himſelf, conſiſtently with the confidence which that prince placed in him, the duty which he owed to his country, and his own intereſt and views, as an expectant of the crown and kingdom of Iſrael. But Providence happily extricated him from this embarraſſment (1 Sam. xxix. 1, &c.); for as the troops of the Philiſtines were paſſing in review before their principal officers, David alſo with his corps marched in the rear, under the command of Achiſh, king of Gath. This circumſtance offended the Philiſtines, and their princes were peremptorily determined not to permit David and his forces to accompany them to the engagement, ſo that Achiſh was induced to diſmiſs David and his followers. On his return to Ziklag, he attacked the Amalekites, and recovered all that they had taken away, their wives and families, and entire ſubſtance; and at Ziklag, he diſtributed his ſhare of the ſpoil partly to thoſe of the elders of Judah, who were his friends, and partly among the inhabitants of thoſe towns, which had given refuge to himſelf and his men, during the time of their perſecution by Saul; and by this act manifeſted his prudence, gratitude, and juſtice.

David now reſided among the Philiſtines, in whoſe country theſe Amelekites had committed great depredations, whilſt the Philiſtines themſelves were engaged in war with the Hebrews, and incapable of defending their own frontiers. He was their ally, obliged to act in their favour, and behaved like a ſoldier of honour, in avenging the injuries that had been done them: and we may obſerve upon the whole, that David's execution of vengeance on the Amalekites for their treacherous invaſion and unprovoked acts of violence, whilſt neither the Philiſtines nor the Hebrews could defend their territories, was a deſerved and neceſſary ſeverity. There are other circumſtances and conſiderations, ſuggeſted by the hiſtory to any impartial and candid reader, which amply vindicate David's expedition againſt the Amalekites. In this expedition he evinced his reſolution and courage, and his zeal in promoting the welfare of his country, though he was in a ſtate of actual baniſhment from it, and forced to ſeek for ſhelter in the dominions of an enemy. He was further enabled to ſecure, and ingratiate himſelf with his former friends, the elders of Judah, by the preſent which he reſpectfully ſent them; and theſe were fortunate circumſtances, as they happened juſt before the death of Saul, who, with his three ſons, were killed in battle againſt the Philiſtines, upon the mountains of Gilboa.

On the third day after David's return to Ziklag (2 Sam. i. 1.) from the ſlaughter of the Amalekites, he was informed by an Amalekite of the death of Saul and his ſons, owning himſelf to be the perſon who killed him, and preſenting David with his crown and bracelet. This wretch intended thus to ingratiate himſelf with David; but he knew not his diſpoſition, and that a crown would be unwelcome to him at the price of treaſon, and that a throne would not tempt him, if it were to be purchaſed by parricide. Could he, who himſelf thrice ſpared Saul's life, when he found it abſolutely in his power, endure the man that boaſted of having murthered him? On this occaſion he behaved with that dignity and juſtice that ſet him above all deſerved reproach, however his conduct may have been unjuſtly criminated.

Upon the death of Saul and his three ſons, David having been ordered by the oracle to go up to Hebron, the capital city of the tribe of Judah, was unanimouſly choſen and anointed king over their whole tribe. It was natural for this tribe to ſeize the opportunity of Saul's death, and to acknowledge him, whom God had pointed out to them for their king; eſpecially as he was of their own tribe, and had gained the general eſteem by his perſonal virtues, and military abilities. This tribe might further have been induced to raiſe David to the throne over them, becauſe they hoped that the ancient prophecy of Jacob (Gen. xlix. 10.) was now about to be accompliſhed. This tribe was alſo the moſt powerful and reſpectable of all the twelve; and as they had a right to chuſe their own prince, they might reaſonably have expected that the other tribes would have followed their example, and, by uniting in David, quietly have ſubmitted to the appointment of God, as they themſelves had done. David was now 30 years old (B. C. 1055); and having, on many occaſions, ſhewn his courage, fortitude, moderation, and patience, and having maintained an invincible purpoſe not to haſten his acceſſion to the throne by any acts of treaſon and violence, God now began to reward his ſingular virtue; and, from a fugitive and exile, he was made king over all the tribes, by their unſolicited and voluntary conſent; as an earneſt of what God had in farther reſerve for him;—the kingdom over all his people. Iſhboſheth, a younger ſon of Saul, was a competitor with David for the ſovereignty. It is acknowledged, that David had no pretenſion to the throne by right of inheritance, and in this reſpect Saul had no more right than David, nor Iſhboſheth than either of them; the hereditary right, if any ſuch right exiſted, being veſted in Mephiboſheth, Saul's grandſon, by his eldeſt ſon Jonathan. Iſhboſheth was the mere creature of Abner, the captain of Saul's hoſt, who, ambitious of retaining the power in his own hands, made Iſhboſheth king over Iſrael by military force; without the choice or conſent of the eleven tribes, and in direct oppoſition to the choice and conſent of the tribe of Judah, and the inclination of the whole body of the people. Iſhboſheth was, therefore, in every reſpect, an uſurper, in prejudice of the right heir;

and David, as well as every man in Iſrael, had a right to oppoſe him, and prevent his eſtabliſhment in the kingdom. The right of David to the crown was indiſputable, and the higheſt by which any man could claim it. Upon the death of Saul, the throne was vacated, and the people were at full liberty, under the direction of God, to chuſe whom they pleaſed. The tribe of Judah, as we have ſaid, unanimouſly elected David for their king, and it is highly probable, that the whole body of the nation would have concurred, if they had not not been prevented by the influence of Abner. A civil war was the conſequence of theſe rival intereſts, which laſted above ſeven years under the influence and ſupport of Abner, with the eleven tribes; but when Abner perceived that his cauſe declined, and that of David proſpered, he availed himſelf of an opportunity that occurred of bringing about a revolution in favour of David. The eaſy method by which Abner effected this revolution, and the cordial manner in which the whole nation ſubmitted to David, are a demonſtration that they approved Abner's change, and were glad to accept David for their king. For no ſooner had Abner a conference with the elders of Iſrael, and put them in mind that they had formerly deſired David for their king, and that the Lord had reſolved to deliver them from the Philiſtines, and their enemies, by the inſtrumentality of David, than all the tribes came to Hebron, all the men of war, "with a perfect heart," and all Iſrael, "with one heart to make him king;" and accordiugly anointed him king over Iſrael. In this whole affair David's conduct appears to be perfectly honourable. Joab, however, reſented David's acceptance of Abner's ſubmiſſion, and having inſulted his perſon, took leave of him, with a reſolution of deſtroying Abner.

In purſuance of this reſolution, Joab, jealous of Abner, and dreading his being ſuperſeded in the command of the army by the advancement of a rival, took the opportunity of a friendly conference treacherouſly to aſſaſſinate him. In this baſe and bloody act David had no concern; ſo far from it, that he expreſſed, in the ſtrongeſt terms, his deteſtation of the baſe act. (2 Sam. iii. 28, 29.) As ſoon as Iſhboſheth was informed of Abner's death, he deſpaired of his cauſe, and gave up all for loſt. The conteſt, however, ſoon terminated in his death; for he fell a ſacrifice to the intereſted and ambitious views of two brothers, who were captains in his guards, and who hoped, by the murder of their maſter, to recommend themſelves to David, and to obtain preferment in his ſervice. David, in juſt abhorrence of this act of treaſon, ordered the perpetrators of it to be immediately executed; and as an expreſſion of reſpect for the memory of Iſhboſheth, he ordered his head to be buried in the ſepulchre of Abner in the city of Hebron. Upon the death of Iſhboſheth, all the elders of Iſrael came to David at Hebron, preſented to him the conditions on which they advanced him to the throne, which being mutually and ſolemnly agreed to, they anointed him king, "according to the word of the Lord, by Samuel," many years before: thus ſettling the government upon a ſolid foundation, and effectually providmg for the national ſecurity and peace. On this occaſion, the hiſtorian obſerves (1 Chron. xii. 40.), "There was joy in Iſrael."

The firſt act of his reign was the ſiege and ſubſequent capture of Jeruſalem from the Jebuſites, together with the fortreſs of Sion, to which he gave the name of the city of David, (2 Sam. v. 11.) whither he transferred the ſeat of government, and where he built a royal palace, making it the metropolis of the kingdom of Iſrael. On the completion of the palace, in which he was aſſiſted by the Tyrians, who were better ſkilled in architecture than the Hebrews, he penned the ode which we have in the 30th pſalm at the dedication of it. David, finding himſelf well eſtabliſhed on the throne, and ſettled in his new-built palace, reſolved to regulate his family and court. The ſcheme he formed for this purpoſe, and the regulations he adopted, are tranſmitted to us in an ode, (Pſ. ci.) which will do honour to his memory, as a good man, and an excellent king, throughout all generations. Beſides attending to his own perſonal convenience, he ſet about enlarging and beautifying Jeruſalem, and committed the care of this public work to Joab. When his public undertakings were finiſhed, which muſt have been ſeveral years in carrying on, he penned the 87th pſalm.

His increaſing proſperity excited the jealouſy of neighbouring nations, the ancient enemies of Iſrael; ſo that ſoon after his eſtabliſhment on the throne, he was obliged to concert meaſures for reſiſting them. Of theſe enemies the Philiſtines took the lead, and kept him employed in repeated conflicts, which terminated on his part in renewed victories. As ſoon as he obtained reſt, by peace at home and freedom from all foreign wars, he devoted himſelf to the buſineſs of making ſome neceſſary regulations in religion, and of providing for the more ſtated performance of the ſolemnities of divine worſhip. With this view he transferred the ark to mount Sion at Jeruſalem. The proceſſion for this purpoſe was accompanied with vocal as well as inſtrumental muſic; and David prepared an ode, (Pſ. lxviii.) to be ſung by the chanters, the ſeveral parts of which were ſuited to the ſeveral diviſions of the march, and the whole of it adapted to ſo ſacred and joyful a ſolemnity. A circumſtance occurred as the ark had juſt arrived at the city of David, or mount Sion, which has occaſioned ſome ſevere cenſures by Mr. Bayle and others: this was his dancing before the ark. But theſe cenſures betray a total ignorance of David's manner of dancing, and the poſtures he made uſe of, which ought to have been known before he could juſtly be charged with having made himſelf ridiculous by them; becauſe perſons may dance in a very briſk and lively manner, without any poſtures that ſhall deſerve contempt; and moreover there is no word in the original, that is made uſe of to expreſs David's behaviour in this proceſſion, that either implies, or will juſtify ſuch a ſuppoſition. David was frequently, during his ſubſequent reign, engaged in wars with the Philiſtines, the Moabites, the Syrians, the Edomites or Idumæans, and the Ammonites, in which he often obtained the moſt ſplendid victories, and by which he was raiſed very high in the eſtimation of the monarchs of the eaſt. In one inſtance, that has been recorded by the ſacred writers without palliation, David's conduct cannot be too ſeverely condemned: he gave himſelf up to the ſway of uncontrouled paſſions; he ruined an innocent woman, and to complete the wickedneſs of the deed, attempted to add murder to the crime of adultery. This was the affair of Bathſheba and Uriah. Much has been ſaid in order to aggravate David's guilt on this occaſion; but we owe it to juſtice and candour duly to conſider, whether there be not, by way of contraſt, any circumſtances of alleviation in this tranſaction. A good mind will derive great ſatisfaction from being able to extenuate guilt, where it can be fairly done, which, as far as it is real, ought never to be concealed or defended. David, at the commencement of this tranſaction, ſeems not to have incurred the charge of deliberation and ſettled purpoſe. Bathſheba was unknown to him, nor was he apprized that ſhe was a married woman, when he firſt caſually ſaw her. Much as he was to be blamed, his ſin, in the firſt inſtance, had not that aggravation which it would have had, if there had been more time and leiſure for reflection, and if he had purſued his criminal inclination, after having ſeriouſly and calmly

weighed

weighed the nature and conſequences of what he was about to do, and uſed, as too many others have done in like caſes, fraud, perfidy, and force to gratify them. Bathſheba herſelf ſeems to have too eaſily yielded to the king's inclination, and thereby rendered it almoſt impoſſible for him to ſuppreſs it. Her compliance ſeems to have been voluntary, unforced, and immediate. The firſt crime being committed, and the dreaded conſequences of it appearing, the unhappy prince found himſelf involved in difficulties, out of which he knew not how to extricate himſelf. Conſcious guilt, concern for his own character, regard for the honour of the partner of his crime, and even fear of his own and her life, the puniſhment of their adultery being death; all united to put him on forming ſome contrivance, how to conceal and prevent the ſcandal of it from becoming public. But all theſe failed him. Bathſheba at any rate muſt be preſerved. His own honour was at ſtake to prevent her deſtruction; and he ſaw but one way left to ſecure that end, which he thought himſelf obliged, at any hazard, to obtain. If Uriah lived, ſhe muſt inevitably die. She muſt have died, ſays Joſephus, (Ant. l. vii. c. 7. §. 1.) as an adultereſs by the laws of her country. Uriah could have demanded the puniſhment. The law was expreſs and peremptory. Which of the two muſt be the victim? Cruel dilemma! It is at laſt determined, that the huſband ſhould be ſacrificed to ſave the wife, whom David's paſſion had made a criminal; and if he had abandoned her to her fate, he would have been cenſured by almoſt every man, as a monſter of perfidy, baſeneſs, and ingratitude. But how was Uriah to be got rid of? Poiſon, aſſaſſination, or a falſe charge of treaſon, or ſome ſecret way of deſtruction, were methods with which the eaſtern princes were well acquainted. David was above them all, and had a kind of generoſity even in his crimes. The man he was to deſtroy was a brave ſoldier, and he cauſes him to fall in the bed of honour, gloriouſly fighting againſt the enemies of his king and country. David's conduct is indeed incapable of vindication, but the circumſtances that have been mentioned afford, in the nature of them, ſome alleviation of his crimes, and ſoften the ſeverity of the hiſtorian who deſcribes them. David having thus, by accumulated guilt, taken off the man that he dreaded ſhould live, took Bathſheba to his palace, and made her his wife, to ſkreen her from a proſecution of adultery, to ſecure her againſt the penalty of death, and in ſome meaſure to repair the injury he had done her; which, as a plurality of wives was not forbidden by that conſtitution and polity under which he lived, was the leaſt compenſation that he could make, and which he was obliged in juſtice and honour to make her. One would have thought, without adverting to the obduracy of guilt, that, after ſuch a complication of aggravated crimes, David, upon a review of his conduct, would have been ſtruck with remorſe, confeſſed his ſins to God, and earneſtly ſupplicated forgiveneſs. But the contrary appears from the hiſtory to have been the caſe. He was for a conſiderable time inſenſible and callous, ſo that Nathan the prophet was employed, by an artfully compoſed fable, to induce the king to pronounce his own condemnation, even without ſuſpecting, or intending it. Bathſheba had been juſt delivered of a ſon, the fruit of her adulterous commerce with David, and who was, in the ſtrictneſs of the letter, "conceived" by his mother "in ſin, and ſhapen in iniquity." David appears to have been fond of the child, and, in the midſt of his joy on this account, Nathan demands an audience, and executes his commiſſion. The dreadful ſentence he pronounced rouſed the conſcience of David, and from the fulleſt conviction of his offence, he immediately made this acknowledgment to Nathan, "I have ſinned againſt the Lord." The pſalms he penned on this occaſion ſhew his deep ſenſe of the guilt he had contracted, and will be a memorial of the ſincerity of his repentance throughout all generations.

Vices of ſuch enormity as thoſe of David rarely paſs unpuniſhed. David met in after-life with much affliction of the ſevereſt kind, which he would naturally impute to the hand of an avenging God for his paſt offences. Abſalom his ſon rebelled againſt him, and was ſtabbed to the heart with three darts by Joab, whilſt he was ſuſpended in the midſt of a tree; contrary to the poſitive orders of David, who was much incenſed by this act of treaſon and murder; and at the ſame time he was deſerted by many of his moſt eſteemed friends. Theſe and other circumſtances excited in the monarch the moſt lively emotions of grief, which are pathetically referred to in the ſacred writings. The latter period of David's life was diſturbed by an attempt of Adonijah to ſeize the crown, which, however, he effectually repelled, by cauſing Solomon to be conſecrated and proclaimed king during his own life.

David, having ſettled Solomon's ſucceſſion to the throne, gave him a particular charge in reference to two ſtate criminals, *viz.* Joab and Shimei. With regard to Joab, David mentions three murders, as the ground of the charge (1 Kings ii. 5, 6.) not to let him die a natural death. They were thoſe of Abſalom, Abner, and Amaſa; and the order reſpecting Joab, according to every principle of equity and juſtice, was worthy of a good king, and fit to be given in the laſt moments of his life. It has been ſaid, indeed, that David was culpable for deferring to put Joab to death ſo long, and entailing the performance of this retributive act of juſtice on his ſon and ſucceſſor. Joab, it ſhould be recollected, was too powerful a ſubject for David to bring to juſtice. He attempted it twice by diſplacing him from the office of general. But he reſtored himſelf to his command by murder and treaſon, in ſpite of David, who ſeized the very firſt opportunity, after Joab's power was broken, of ordering his execution. It ſhould be conſidered farther, that whatever Joab's paſt ſervices had been to David, and however faithful he had formerly been to him, yet he had now been engaged in a treaſonable conſpiracy againſt him, to ſet aſide the intended ſucceſſion to the crown, and had actually proclaimed Adonijah king of Iſrael, during his father's life; altogether without, and even contrary to his conſent. The order reſpecting Shimei the Benjamite was founded on his having railed at and curſed David, pelting him with ſtones, and crying out to him, "Come out, come out, thou bloody man, and thou man of Belial, &c." (2 Sam. xvi. 5—9.) This charge againſt David as a bloody man, becauſe the blood of the houſe of Saul was upon him, was a ſcandalous falſehood, and uttered in the madneſs of the paſſion and malice of a man, who, being of Saul's houſe and family, was enraged to ſee that family rejected from the throne, and David advanced to it in their ſtead. David very properly reminded his ſucceſſor, that Shimei was an implacable enemy to his perſon and family, one who was not to be truſted, and would not fail to ſhow his hatred when a proper opportunity occurred. David's direction to Solomon may be underſtood to mean, that he ſhould not put Shimei to death for having curſed him, becauſe he had forgiven him upon oath; but at the ſame time he ſhould not hold him guiltleſs; leaving it to Solomon's wiſdom to inflict a proper puniſhment upon him, provided it was not a capital one. It is certain that Solomon did not underſtand his father as ordering Shimei to be put to death; but only that he ſhould keep a watchful eye over him, and prevent him from all ſeditious practices for the future. Accordingly he ordered him to build a houſe for himſelf

ſelf at Jeruſalem, where he confined him, that he might be perpetually under his inſpection, and bound him never to go farther out of it than the brook Kidron; telling him, that "whenever he paſſed it, he ſhould ſurely die." Shimei himſelf, ſenſible of Solomon's great kindneſs to him, approved the ſentence pronounced upon him, and therefore the charge that David gave him, promiſing him, upon oath, obedience to the condition, on which his life was afterwards to depend.

David died at Jeruſalem in about the 70th year of his age, B. C. 1015, having reigned over Judah 40, and over all Iſrael 33 years. Although his character was far from being faultleſs, he had unqueſtionably many excellent qualities: he is deſcribed in the ſcriptures as "a man after God's own heart;" a phraſe which referred to the qualifications that he poſſeſſed, for carrying into effect the deſigns of Providence, and to his ſteady zeal in the worſhip of the living God, in oppoſition to the idolatry of ſurrounding nations, with which the Iſraelites had been but too often infected. "The man after God's own heart" ſtands in direct oppoſition to the character of Saul, who is deſcribed as acting fooliſhly, by breaking the commandment of God by his prophet, and rejected by him, *i. e.* deprived of the ſucceſſion to the crown in his family, on account of his folly, preſumption, and diſobedience. And it therefore means one, who ſhould act prudently, and obey the commandments of God delivered to him by his prophets, and whom, therefore, God would *thus far* approve and continue to favour. Thus the expreſſion is actually interpreted by the Chaldee paraphraſe; גבר עביד רעותיה, the man who doth my will; and by St. Paul to the Jews at Antioch, who ſays (Acts xiii. 22.) "I have found David, the ſon of Jeſſe, a man after my own heart," *who ſhall execute my will.* There are, therefore, two ſenſes which are evidently implied in this character of "the man after God's own heart;" a man, who ſhould faithfully execute the will of God, according as he was commanded, and who, on that account, and ſo far, ſhould be the object of his approbation. In one or other, or both of theſe ſenſes, the expreſſion is always uſed. David, therefore, is characterized as "a man after God's own heart;" not to denote the utmoſt height of purity in his moral character, as a private man, which by no means enters into the meaning of the expreſſion, and which in no one ſingle inſtance is intended by it; but to repreſent him as one, who, in his public character, as king of Iſrael, was fit for the purpoſes to which God advanced him, and who he knew would faithfully execute the commands he ſhould give him, by his prophets; and who, on this account, ſhould be favoured and approved of God, and eſtabliſhed, himſelf and family, on the throne of Iſrael.

The particular purpoſes for which God advanced him to the throne were, that by his ſteady adherence to the one true God, and the religion which he was pleaſed to eſtabliſh by Moſes, he might be an illuſtrious example to all his poſterity that ſhould reign after him; and here he was abſolutely without blemiſh, and "a man," in the ſtricteſt ſenſe of the expreſſion, "after God's own heart;" as he never departed from his God, by introducing the deities of other nations, or permitting and encouraging the impious rites which they performed in honour of them. There was another end of providence, in David's appointment to be king over Iſrael; that, according to God's promiſe concerning him (2 Sam. iii. 10.) he might "ſave his people Iſrael out of the hands of the Philiſtines, and out of the hand of all their enemies;" and farther, that by him he might accompliſh the more ancient promiſes (Gen. xv. 18.) which God had made to Abraham, in their full extent, of giving to his ſeed "the whole country, from the river of Egypt unto the great river, the river Euphrates." And finally, God raiſed him up to exalt the glory of his people Iſrael, and to render them a flouriſhing and happy people, by the wiſdom and juſtice of his government. (Pſ. lxxviii. 71, 72.)

"See here, then, the true portrait of "the man after God's own heart," who fulfilled all his pleaſure! A prince, who, amidſt all the idolatries of the nations around him, never wickedly apoſtatized from the worſhip of his God, and was an amiable example of a ſteady adherence to thoſe forms of religion, which God had preſcribed, to all the princes his ſucceſſors; who, though king, ſubjected himſelf to God, the ſupreme king of Iſrael, and faithfully executed the commands he received from him; who made his people triumph in the numerous victories he obtained, by the directions, and under the conduct of God himſelf; who enlarged their dominions, and put them into poſſeſſion of all the territories God had promiſed to their forefathers; and who, amidſt all the ſucceſſes that were granted him, the immenſe riches he had gathered from the ſpoils of his conquered enemies, and the ſovereign power with which he was inveſted, never degenerated into deſpotiſm and tyranny, never oppreſſed his people; but governed them with integrity, ruled over them with moderation and prudence, impartially diſtributed juſtice, left an eſtabliſhed durable peace, and fixed the whole adminiſtration, both civil and religious, upon the moſt ſubſtantial and durable foundation. In theſe inſtances he was the true vicegerent of God, on whoſe throne he ſat, and all whoſe pleaſure, in theſe great inſtances, he faithfully performed. If therefore David's private moral character was worſe than it will be ever proved to be, he might be ſtill "a man after God's own heart," in the proper original ſenſe of the expreſſion; and the attempt to prove that he was not poſſeſſed of the height of moral purity, is an impertinent attempt to prove David not to be, what the ſacred hiſtory never aſſerted him to be."

As a juſt delineation of the character of David, and of the principal events of his life, is of great importance in its connection with a due regard to the ſacred writings, and with religion, we have extended it to a conſiderable length; and we ſhall cloſe it with the following abſtract of his hiſtory, with which we are furniſhed by a learned writer: A ſhepherd youth, David, the youngeſt ſon of Jeſſe, was choſen of God to be king of Iſrael, and at his command anointed to this dignity by the hands of Samuel, a venerable prophet, in the room of Saul; who had been rejected for his diſobedience to the divine orders, in feloniouſly ſeizing to his own uſe, the prey of an enemy, which God, the ſupreme king of Iſrael, had devoted to deſtruction. He is introduced to court as a man expert in muſic, a mighty valiant man, a man of war, prudent in matters, a comely perſon, and one favoured of the Lord. By his ſkill in muſic, he relieved Saul under a melancholy indiſpoſition that had ſeized him, was highly beloved by his royal maſter, and made one of his guards. In a war with the Philiſtines he accepted the challenge of a gigantic champion, who defied the armies of Iſrael, and being ſkilful at the ſling, he ſlew him with a ſtone, returned ſafely with his head, and thus ſecured to his prince an eaſy victory over his country's enemies. The reputation he gained, by this glorious action, raiſed an incurable jealouſy and reſentment againſt him, in the mind of the king his maſter; who, after two unſucceſsful attempts to murther him, married him to his younger daughter, that ſhe might be a ſnare to him, and that he might cauſe him to fall by the hands of the Philiſtines:

tines; ſending him upon an expedition againſt them, to bring in an hundred of their foreſkins, in which he hoped he would have met with his own deſtruction. In this exalted ſtation, and amidſt the dangers that encompaſſed him, he behaved with ſingular prudence, ſo that he was in high eſteem both in the court and camp. The modeſty and prudence of his behaviour, and his approved courage and reſolution, gained him the confidence and friendſhip of Jonathan, the king's eldeſt ſon, "who loved him as his own ſoul," became his advocate with his father, and obtained from him a promiſe, confirmed by an oath, that he would no more attempt to deſtroy him. But his jealouſy returned by a freſh victory David gained over the Philiſtines; who, finding the king was determined to have his life, retired from court, and was diſmiſſed in peace by Jonathan, after a ſolemn renewal of their friendſhip, to provide for his own ſafety. In this ſtate of baniſhment, there reſorted to him companies of men, who were uneaſy in their circumſtances, oppreſſed by their creditors, or diſcontented with Saul's tyrannical government, to the number of ſix hundred men, to protect him from the violence of his unreaſonable perſecutor; whom he kept in the moſt excellent order, exerciſed in the moſt friendly ſervices, and by whoſe valour he gained ſignal advantages for his country; but never employed them in oppoſition to, or rebellion againſt the king, or in a ſingle inſtance to diſtreſs or ſubvert his government. Such was the veneration he paid him, and ſo ſacred the regard he had for his life, ſuch the generoſity of his temper, that though it was thrice in his power to have him cut off, he glorioufly ſpared him, and was abſolutely determined never to deſtroy him, whom God had conſtituted the king of Iſrael. His friendſhip with Jonathan, the king's ſon, was a friendſhip of ſtrict honour, whom he never ſeduced from his allegiance and filial duty; in him Jonathan had ſo firm a confidence, that as he knew he would be king, he promiſed himſelf he ſhould be the next perſon in dignity and authority under him; and with his friend David covenanted by oath, that "he would not cut off his kindneſs from his houſe for ever." Being provoked by a churliſh farmer, who evil treated and abuſed his meſſengers, he, in the warmth of his temper, ſwore he would deſtroy him and his family; but was immediately pacified by the addreſs and prudence of a wife, of whom the wretch was unworthy; her he ſent in peace and honour to her family, and bleſſed for her advice, and keeping him from avenging himſelf with his own hand. Being forced to baniſh himſelf into an enemy's country, he was faithful to the prince who protected him; and, at the ſame time, mindful of the intereſt of his own nation, he cut off many of thoſe, who had haraſſed and plundered his fellow-ſubjects. When preſſed by the king, into whoſe dominions he retired, to join in a war againſt his own country, and father-in-law, he prudently gave him ſuch an anſwer as his ſituation required; neither promiſing the aid demanded of him, nor tying up his hands from ſerving his own prince, and the army that fought under him; only aſſuring him in general, that he had never done any thing that could give him juſt reaſon to think he would refuſe to aſſiſt him againſt his enemies. Upon the death of Saul, he cut off the Amalekite who came to make a merit of having ſlain him; and by the immediate direction of God, who had promiſed him the ſucceſſion, went up to Hebron, where, on a free election, he was anointed king over the houſe of Judah; and after about a ſeven year's conteſt, he was unanimouſly choſen king by all the tribes of Iſrael, "according to the word of the Lord by Samuel," upon the death of Iſhboſheth, who was treacherouſly murthered by two of his own captains; whom David juſtly cut off for their perfidy, treaſon, and parricide.

As king of Iſrael, he adminiſtered juſtice and judgment to all his people, was a prince of courage, and great military prudence and conduct; had frequent wars with the neighbouring nations, to which he was generally forced by their invading his dominions, and plundering his ſubjects; againſt them he never loſt a battle; he never beſieged a city without taking it, nor, as for any thing that can be proved, uſed any ſeverities againſt thoſe he conquered, beyond what the law of arms allowed, his own ſafety required, or the cruelties of his enemies rendered juſt, by way of retaliation; enriching his people by the ſpoils he took, and providing large ſtores of every thing neceſſary for the magnificent temple he intended to erect, in honour of the God of Iſrael. Having reſcued Jeruſalem out of the hands of the Jebuſites, he made it the capital of his kingdom, and the place of his reſidence; and being willing to honour it with the preſence of the ark of God, he brought it to Jeruſalem in triumph, and diveſting himſelf of his royal robes, out of reverence to God, he clothed himſelf in the habit of his miniſters, and with them expreſſed his joy by dancing and muſic; contemned only by one haughty woman; whom, as a juſt puniſhment of her inſolence, he ſeems ever to have ſeparated from his bed. Though his crimes were heinous, and highly aggravated, in the affair of Uriah and Bathſheba, he patiently endured reproof, humbly ſubmitted to the puniſhment appointed him, atoned for his ſins, as far as he could, by a ſincere repentance, and obtained mercy and forgiveneſs from God, though not without ſome ſevere marks of his diſpleaſure, for the grievous offences he had been guilty of. A rebellion is raiſed againſt him by his ſon Abſalom, whoſe life he commanded the general to ſpare. When forced by it to depart from Jeruſalem, he prevented the juſt puniſhment of a wretch who curſed and ſtoned him. When reſtored to his throne, he ſpared him upon his ſubmiſſion, and would not permit a ſingle man to be put to death in Iſrael upon account of it. He, with a noble confidence, made the commander of the rebel forces general of his own army, in the room of Joab, whom he intended to call to an account for murder and treaſon. After this, when obliged, by the command of God, to give up ſome of Saul's family to juſtice, for the murder of the Gibeonites, he ſpared Mephiboſheth, Micah, and his family, the male deſcendants of Saul and Jonathan, who alone could have any pretence to diſpute the crown with him, and ſurrendered only Saul's baſtard children, and thoſe of his daughter by Adriel, who had no right or poſſible claim to the throne, and could never give him any uneaſineſs in the poſſeſſion of it; and thus ſhewed his inviolable regard for his oaths, his tenderneſs to Saul, and the warmth of his gratitude and friendſhip to Jonathan. In the cloſe of his life, and in the near proſpect of death, to demonſtrate his love of juſtice, he charges Solomon to puniſh with death Joab, for the baſe murder of two great men, whom he aſſaſſinated under the pretence of peace and friendſhip; and to manifeſt his care of his ſucceſſor's ſafety, and prevent any diſturbances in the beginning of his government, he charges him to have an eye on the conduct of an old turbulent rebel, and, except cutting him off, to deal with him according to his prudence, and not to ſpare him if he found any thing in him worthy of death. And as if one thing more was wanting to complete the catalogue of his noble actions, he profeſſed the greateſt regard for every appearance of virtue and holineſs, and gave the moſt ſhining and indiſputable proofs of an undiſſembled reverence for, and ſincere piety to God; ever

obeying

obeying the direction of his prophets, worſhipping him alone throughout the whole of his life, and making the wiſeſt ſettlement to perpetuate the worſhip of the ſame God, throughout all ſucceeding generations.

And as to his pſalms, they breathe the genuine diſpoſition of piety; they are wrote with a true ſpirit of poetry; the ſentiments to be found in them are often the moſt grand and ſublime, which have nothing in pagan poetry to exceed, or equal them; and which, had they been wrote on any other ſubjects but thoſe of religion, would have been regarded as the proofs of a moſt excellent genius; and his admirers would have wondered at the calmneſs and ſedateneſs of his temper, who, amidſt the multiplicity of his affairs, the variety of the perſecutions he ſuffered, the imminent dangers that ſurrounded him, and the numerous wars he was engaged in, could find any leiſure hours, or tranquil diſpoſitions, for the polite and delicate entertainments of poetry and muſic.

Theſe, Chriſtians, are the out-lines of a Jewiſh prince, whom you juſtly extol as "a man after God's own heart;" whom God himſelf called to be king over Iſrael, who faithfully anſwered the purpoſes for which God raiſed him; in whoſe family he eſtabliſhed the throne; with whom he made an everlaſting covenant; and who was the great progenitor of the Meſſiah himſelf, who now reigns over all, and "ſhall reign till all his enemies are put under his feet." Chandler's Critical Hiſtory of the Life of David, 2 vols. 8vo. paſſim.

The holy and royal pſalmiſt ſeems to have owed his riſe in a great meaſure to his muſical talents. He was firſt noticed and ſent for to Saul when troubled with the evil ſpirit, as Farinelli was to the king of Spain, to try the medical power of muſic. "And it came to paſs, when the evil ſpirit from God was upon Saul, that David took an harp and played with his hand; ſo Saul was refreſhed, and was well, and the evil ſpirit departed from him." 1 Sam. chap. xvii. v. 23. This was previous to the proof of David's proweſs in ſlaying Goliah, at which time, however, Saul did not recognize him as the muſician, who had put to flight the evil ſpirit; but inquired who he was?

If it be poſſible for muſic to operate medicinally with ſucceſs, it may be imagined a palliative, at leaſt, if not a cure, for a troubled ſpirit. The human mind, under the preſſure of affliction, or warped and agitated by the contention of warring paſſions, ſeems a fit ſubject for ſoft and ſoothing ſtrains to work upon, as powerful anodynes.

Without having recourſe to a miracle in the caſe of Saul, who had offended the Divinity by his diſobedience, the whole of David's power over the diſorder of that unfortunate prince, might be attributed to his ſkilful and affecting manner of performing upon the harp.

"And Saul's ſervants ſaid unto him, Behold now, an evil ſpirit from God troubleth thee. Let our lord command now thy ſervants which are before thee, to ſeek out a man who is a cunning player on a harp. And it ſhall come to paſs when the evil ſpirit from God is upon thee, that he ſhall play with his hand, and thou ſhalt be well. And Saul ſaid unto his ſervants, Provide me now a man that can play well, and bring him to me. Then anſwered one of the ſervants, and ſaid, Behold, I have ſeen a ſon of Jeſſe the Bethlehemite, that is cunning in playing, and a mighty valiant man, and a man of war; and prudent in matters, and a comely perſon, and the Lord is with him."

"Wherefore Saul ſent meſſengers unto Jeſſe, and ſaid, Send me David thy ſon, which is with the ſheep. And Jeſſe took an aſs, laden with bread, and a bottle of wine, and a kid, and ſent them by David his ſon unto Saul. And David came to Saul, and ſtood before him. And he loved him greatly, and he became his armour-bearer. And Saul ſent to Jeſſe, ſaying, Let David, I pray thee, ſtand before me; for he hath found favour in my ſight. And it came to paſs, when the evil ſpirit from God was upon Saul, that David took an harp, and played with his hand: ſo Saul was refreſhed, and was well, and the evil ſpirit departed from him."

It was very natural for the power of this medicine to ceaſe, when the patient had no more faith in him who adminiſtered it; but, on the contrary, regarded him with a jealous eye, as one aſpiring at his crown; and who, if he did not conſpire againſt his life, muſt look upon it as an impediment to his exaltation, and impatiently wiſh for its termination: for Saul not to have had theſe ideas forced upon his mind, he muſt have been more, or leſs, than mortal. The human paſſions, thoſe gales of life, muſt either have been annihilated, or ſublimed by angelic refinement. But the hiſtory of this prince furniſhes too many inſtances of human weakneſs and frailty, to allow us to ſuppoſe him either inſenſible, or ſuperior to his ſituation. We muſt therefore ſuppoſe his diſeaſe now to have become too powerful for ſo gentle a remedy as muſic. Nor ought we to imagine that a diſeaſe, or "an evil ſpirit from the Lord, with which he was troubled," was intended to be radically cured by human means, though it had at firſt given way to them.

Soon after David had manifeſted by this inſtance his muſical ſkill, we find him a volunteer in the army of Saul, and giving extraordinary proofs of his military proweſs, by his victory over Goliah, the champion of the Philiſtines, who had ſtruck ſuch a terror into his countrymen, that they all declined to accept his challenge, regarding him as invincible. David returning from the field of battle after his victory over the giant, was met by the women of all the cities of Iſrael, "ſinging and dancing, with tabrets, with joy, and with inſtruments of muſic." 1 Sam. xviii. 6. "And the women anſwered one another as they played, and ſaid," &c. This is an indubitable proof of a chant in dialogue, or, à dui cori, being in early uſe: and it was this which probably gave riſe to the manner of chanting the pſalms in the cathedral ſervice. Pſal. lxviii. ver. 25, the damſels play with timbrels in the proceſſion before the ark. Women, even, ſays Don Calmet, whom the apoſtle forbids to ſpeak in church, had the privilege to ſing there in company with the men. But many proofs might be alleged of a permiſſion being given for females to aſſiſt in the performance of ſacred rites. In 1 Chron. chap. xxv. where the muſical eſtabliſhments for religious purpoſes are all enumerated, we are told, that "God gave to Heman fourteen ſons and three daughters. And all theſe were under the hands of their father for ſong, in the houſe of the Lord, with cymbals, pſalteries, and harps." But Miriam, Deborah, Judith, and Anne, the mother of Samuel, are all regarded by the Jews, not only as ſingers, but as poeteſſes and propheteſſes.

In the reign of king David, muſic was held in the higheſt eſtimation by the Hebrews. The genius of that prince for muſic, and his attachment to the ſtudy and practice of it, as well as the great number of muſicians appointed by him for the performance of religious rites and ceremonies, could not fail to extend its influence, and augment its perfections: for it was during this period that muſic was firſt honoured, by being admitted in the miniſtry of ſacrifice, and worſhip of the ark; as well as by being cultivated by a king.

"And David, and all the houſe of Iſrael, played before

the lord, on all manner of inſtruments, made of firwood, even on harps and on pſalteries, and on timbrels, and on cornets, and on cymbals." 2 Sam. chap. vi. ver. 5.

This is related 1 Chron. chap. xiii. ver. 8. in nearly the ſame words:

"And David and all Iſrael played before God with all their might, and with ſinging and with harps, and with pſalteries, and with timbrels, and with cymbals, and with trumpets."

In all the tranſlations theſe inſtruments are differently named. In the Syriac we are told, that David and all Iſrael ſung before the Lord, accompanied by the cithara, pſaltery, cymbal, and ſiſtrum.

The joy which David ſhewed, upon this occaſion, in leaping, dancing, ſinging, and playing, almoſt naked, before the ark, ſeemed, in the eyes of his queen Michal, to exceed the bounds of moderation, ſo much, that when ſhe ſaw him from the window, "ſhe deſpiſed him in her heart," 2 Sam. vi. 16. and, afterwards, upbraided him, in terms not very honourable to muſicians in general.

"And Michal, the daughter of Saul, came to meet David, and ſaid, How glorious was the king of Iſrael today, who uncovered himſelf in the eyes of the hand-maids of his ſervants, as one of the vain fellows ſhameleſsly uncovereth himſelf!"

Now it is much to be feared, that by the vain fellows, the queen meant Levitical ſingers, muſicians by trade, who, perhaps, like the ancient prieſts of the Syrian goddeſs, the Galli, uſed to ſing and play in the proceſſions naked.

In the fifteenth, ſixteenth, and twenty-third chapters of the firſt book of Chronicles, there is a particular account and enumeration of all the muſicians appointed by David in the ſervice of the ark, before a temple was erected. 1 Chron. xxiii. 5. David appoints four thouſand of the Levites to praiſe the Lord with inſtruments; and chap. xxv. v. 1. the number of ſuch as were inſtructed, and were cunning in ſong, is ſaid to have been two hundred four-ſcore and eight.

And, 1 Chron. ix. 33. we are told of "the ſingers, chief of the fathers of the Levites, who remaining in the chambers, were free: for they were employed in that work day and night."

Before this time, it does not appear from the ſacred writings, that any other inſtruments than trumpets, or ſinging, than in a general chorus of the whole people, was uſed in the daily celebration of religious rites; though others are mentioned in proceſſions, and on occaſions of joy and feſtivity.

The royal pſalmiſt may well be ſtyled by the Hebrews the "Sire of Sacred Song;" as his ſublime poetical effuſions and inſpirations not only procured his nation ſuch a muſical eſtabliſhment, as ſeems not to have been equalled in the ſervice of religion in any other kingdom or empire in the world; and the canticles, hymns, and pſalms, then produced, are ſtill in reverence and uſe throughout Chriſtendom, at the diſtance of 2856 years from the commencement of this tuneful and inſpired monarch's reign.

DAVID, JOHN PETER, a native of the town of Gea, was initiated into the practice of ſurgery under M. le Cat, whoſe daughter he married, in 1764. On the death of Le Cat, David ſucceeded to the places of ſurgeon-in-chief to the hotel dieu at Paris, and profeſſor of anatomy. He was alſo member of the Royal Academy of Sciences, and author of ſeveral uſeful practical works; the titles of the moſt noted are, "Recherches ſur la maniere d'agir de la Saignee," 1763, 12mo. The ſame year he publiſhed "Diſſertation ſur ce qu'il convenient de faire, pour diminuer ou ſupprimer le lait de females;" alſo "On the Manner of treating Pregnant Women, or Cautions with the view of preventing Abortion, or the premature Birth of the Child;" and in 1771, "A Philoſophical Diſſertation on the Figure of the Earth." Haller. Bib. Eloy. Dict. Hiſt.

DAVID I., king of Scotland, was brought up in England, where he married Maud, a grand-niece of William the Conqueror. He ſucceeded his brother in 1124. The earldoms of Northumberland and Huntingdon devolved on him; but on his return to Scotland, he was welcomed with every mark of reſpect and joy. His reign was proſperous: and his attention to the adminiſtration of juſtice was truly exemplary. He decided himſelf the controverſies of the nobles, and watched with the greateſt aſſiduity over the conduct of the ordinary judges. On the death of Henry I., king of England, he vindicated the cauſe of his daughter, the empreſs Maud, and that of her ſon, who was afterwards Henry II., againſt the uſurpation of Stephen. To Stephen he refuſed the cuſtomary homage for his Engliſh eſtates, and obliged the northern nobles to ſwear allegiance to Maud. At length, in 1139, a negociation took place, and Henry was put in poſſeſſion of all the Engliſh eſtates, on condition of acknowledging the power of Stephen. Maud afterwards landed in England, and ſent her ſon Henry to Carliſle, to receive the honour of knighthood from David. The remainder of his reign was proſperous, excepting the affliction which he felt for the loſs of his only ſon. He died at Carliſle in the year 1153, after a reign of twenty nine years.

DAVID II., king of Scotland, ſon of Robert Bruce, was only five years old at the death of his father in 1329; he had, however, for political reaſons, been already betrothed to Joan, ſiſter of Edward III. of England. The earl of Murray was appointed guardian to the young king, who ſoon found a rival in the perſon of Edward, ſon of John Baliol, who, ſupported by the Engliſh, invaded the kingdom, was proclaimed king, and David, like his father, did homage as vaſſal of England. For the preſent the youthful king and his ſpouſe were ſent to France for ſecurity. The Scots made a noble ſtand for independence: the patriotic cauſe at length became triumphant, and David returned from the continent in the year 1342. He was received with joy, and made proper returns of gratitude to thoſe who had vindicated his cauſe. He now thought of revenging himſelf on England, and in 1346 he invaded the northern counties, and made great havock in his progreſs. In a pitched battle fought at Neville's-croſs near Durham, he was defeated and taken priſoner. The king was carried to London, and confined in the tower till 1357, when he received his liberty, with an acknowledgment of his right to the crown, upon condition of a large ranſom. On his return, he altered the ſucceſſion to the throne from the ſon of his eldeſt to the ſon of his youngeſt ſiſter. He employed himſelf during the remainder of his reign, in compoſing the feuds and diſorders which prevailed in his own kingdom. He was often in England for the purpoſe of negociation with Edward, who ſeems to have gained a complete aſcendancy over him; ſo that David ventured to propoſe to his ſtates, that Edward or his ſon ſhould ſucceed him. This propoſal, however, was not only rejected with indignation, but nearly occaſioned an inſurrection. His queen dying, he married a ſecond time, but had no iſſue. He died in 1371, in the 47th year of his age. Univer. Hiſt.

DAVID, EL DAVID, one of the falſe Meſſiahs of the Jews, who appeared at the end of the 12th century in Perſia; he profeſſed himſelf the promiſed Meſſiah, who was deſtined by heaven to lead them back to Judea, to re-eſtabliſh the kingdom and throne of David. His followers took up arms in his defence, and committed various acts of hoſtility. At length he was betrayed and beheaded. His enterpriſe proved highly

highly diſaſtrous to the Jews throughout the Perſian dominions, vaſt numbers of whom were plundered and butchered without any mercy, and without diſtinction of age or ſex, in revenge for the outrages which they had committed during their progreſs to the power and glory which they anticipated under their leader. Moreri.

David, Francis, a learned divine in the 16th century, was a native of Hungary. Of the place of his birth we have no account, nor are we informed under whom he ſtudied; he began life a Catholic, and employed his talents in oppoſing the progreſs of Calviniſm in Tranſylvania; he afterwards became a convert to the Lutheran faith, which he ſoon abandoned for the principles of the reformed church. He was next the advocate of Unitarianiſm in its moſt ſimple ſtate. He oppoſed Socinus in the notion of giving worſhip to Jeſus Chriſt, declaring that to invoke him was an unchriſtian error, which muſt incur the diſpleaſure of the Supreme Being; and that it was equally lawful to pray to the Virgin Mary and other deceaſed ſaints, who have at no time given evidence, either that they can hear our prayers, or beſtow any thing upon us. He is ſaid to have held ſome notions nearly allied to Judaiſm, and hence he and his party were called ſemi-Judaizers. David was perſecuted by Socinus and the ſect over which he preſided, and by their means, or at leaſt by their connivance, he was thrown into priſon, where he languiſhed for ſome years, until his death, which happened in 1579. He was author of "A Letter to the Churches of Poland, on the ſubject of Chriſt's Reign of a thouſand years upon Earth," and various other pieces. Moreri. See alſo the article Socinus in this dictionary.

David's, St., in *Geography*, is a city and ſee of a biſhop in the cantreve of Dewiſland, or land of St. Dewy, i. e. St. David, and county of Pembroke, South Wales, England. It is ſixteen miles ſouth-weſt of Haverford-weſt, and two hundred and fifty-ſeven from London. The city ſtands near the promontory of Pebidiog, the *Octopitarum* of Ptolemy, called in Engliſh St. David's head. It is a poor ill-built place, and only famous for its cathedral, which was built, according to Gyraldus, by Peter As, dioceſan, in the time of Henry II. but completed, according to Willis, in the reign of king John. It preſents at this time only the remains of its former ſplendour. The nave, conſidered as part of the original building, has ſeveral chapels and oratories in a ruinous ſtate, and containing many ancient monuments. In the choir are the tombs of Owen Tewdwr, or Tudor, and Edmund earl of Richmond, father to Henry the ſeventh. "It was this tomb, and the proud memorials of his other Tewdwr anceſtors, which induced king Henry VIII. to change the intention he had formed of removing the ſee to Carmarthen, as a more central and eligible part of the dioceſe." The modern church has been lately repaired and improved; the cieling of Iriſh oak is much admired, together with a perfect Moſaic pavement The arch-epiſcopal ſee was removed to this place from Caerleon, owing to the perſecution of the Chriſtians under the reign of Diocletian, by its biſhop, David. From that time it had ſeven ſuffragan biſhoprics, but by the encroachments of the Engliſh, the ſees were ſucceſſively alienated, the archbiſhopric reduced to a ſingle dioceſe, and by the policy of the Engliſh court, the biſhopric became ſuffragan to the ſee of Canterbury.

The members of the preſent cathedral are the biſhop, who is alſo dean, a precentor, chancellor, treaſurer, four archdeacons, eight prebendaries, ſix canons, and curſal, amounting to twenty-two, which is the number of prebends. The other members are, a ſub-chanter, four prieſt-vicars, four lay-vicars, an organiſt, four choriſters, a maſter of the grammar-ſchool, a verger-porter, ſexton, and keeper of the church; in the whole forty-one.

The epiſcopal palace is now in ruins, and the biſhop's uſual reſidence is at Abergwily, near the town of Carmarthen. St. David's has neither fair nor market. The number of inhabitants cannot be exactly ſpecified. By the returns under the late act for the cantreve, or hundred, the number of houſes was 414, and of inhabitants 1803. Near St. David's-head is the iſland of Ramſey, called in Britiſh *Ynys Devanog*, the ancient Linden of the Romans; upon which once ſtood a chapel, dedicated to Devanus or St. Devanog. The iſland, which is the property of the biſhop, abounds with rabbits, and is famous for a peculiar breed of wild ſheep, nearly reſembling the *mouflon* or the animal in its natural ſtate. Near Ramſey are ſeven ſmaller iſlands, called "*the Biſhop and his Clerks*," in alluſion to the original inſtitution of St. David's. They are little more than bare rocks, and are extremely dangerous to ſhips coming from the weſtward, when the wind blows ſtrongly in ſhore. Evans's Tour through South Wales. Brown Willis's Hiſtory of St. Davids. Malkin's Scenery of South Wales.

David's-*Iſland*, St., a pariſh in the Bermuda iſlands.

David's-*Point*, a cape on the north coaſt of the iſland of Grenada. N. lat. 12° 20'. W. long. 61° 26'.

David's-*Town*, a town of America, ſeated on the Aſſanpink river, in the ſtate of New Jerſey, and county of Hunterdon, 10 or 12 miles from Trenton. A boat navigation has been lately opened by means of three locks between theſe towns.

DAVIDE, Giacomo, in *Biography*, one of the greateſt opera ſingers, with a tenor voice, that appeared on our ſtage during the laſt century. He arrived in England after we had ceaſed to have a capital performer with a *ſoprano* voice, and ſupplied his place, performing all the firſt men's parts as long as he ſtaid in this country. When he came here his voice was perhaps not ſo good as it had been; but he was a very great ſinger, with a good figure, and an excellent actor. He was not without pathetic powers, and expreſſion; but he had ſuch a facility in running diviſions, that he rendered *bravura* every air he ſung, into which he conſtantly introduced certain curious paſſages of reſearch and ſtudy, which were probably of his own invention, and which no other ſinger could execute; ſo that by too frequent repetition, they loſt their effect, by ceaſing to ſurpriſe, and to be thought wonderful! He never let a ſimple and plain paſſage be heard, which with his fine voice and ſober expreſſion would have pleaſed more, and with leſs expenditure of notes, than by all the unintelligible and unfelt difficulties with which he could diſguiſe the original melody. In ſhort, it was one general cry, that "he ſung too much," which the Italians expreſs by two ſimple words, *canta troppo*.

We have heard nothing of him lately; and he has probably ere now retired from the ſtage, if not from this world.

DAVIDISTS, Davidici, or David Georgians, a ſect of heretics, the adherents of David George, a native of Delft, who, in 1525, began to preach a new doctrine, publiſhing himſelf to be the true Meſſiah: and that he was ſent thither to fill heaven, which was quite empty for want of people to deſerve it. He is likewiſe ſaid to have denied the exiſtence of angels, good and evil, of heaven and hell, and to have rejected the doctrine of a future judgment. He rejected marriage, with the Adamites; held, with Manes, that the ſoul was not defiled by ſin; and laughed at the ſelf-denial ſo much recommended by Jeſus Chriſt. Such were his principal errors. He made his eſcape from Delft, and retired firſt into Frieſland, and then to Baſil, where he changed his name, aſſuming that of John Bruck, and died in 1556.

He left ſome diſciples behind him, to whom he promiſed, that he would riſe again at the end of three years. Nor was he altogether a falſe prophet herein; for the magiſtrates of that city being informed, at the three years end, of what he had taught, ordered him to be dug up, and burnt, together with his writings, by the common hangman.

There-

There are ſtill ſome remains of this ridiculous ſect in Holſtein, Frieſland, and other countries, whoſe temper and conduct ſeem to diſcredit the exaggerated account which ſome writers have given of their founder. He was probably a deluded fanatic and myſtic.

DAVIDOVA, in *Geography*, a lake of Ruſſia, in the government of Toboſk, 208 miles N.N.E. of Turuchanſk.—Alſo, a town of Ruſſian Siberia, on the Lena, in the government of Irkutſch; 24 miles N.N.W. of Vercholenſk.—Alſo, a town of Ruſſian Siberia, in the government of Irkutſch, on the Kirenga: 60 miles S. of Kirenſk.

DAVID'S-HYTTAN, a ſmall town of Sweden, in the province of Daland or Dalecarlia, remarkable for its ſteel manufactory.

DAVIDSO, or Davo, an iſland of Sweden in the province of Weſtmannland, which derives its name from St. David, the firſt preacher of the goſpel in Weſtmannland, who came from England about the year 1060, and founded a convent in this place.

DAVIDSON, a county of America, in Mero diſtrict, Teneſſee, bounded N. by the ſtate of Kentucky, E. by Sumner, and S. by the Indian territory. The chief town, Naſhville, lies on the great bend of Cumberland river, and is alſo watered by the Harpith and Stones rivers. It contains 9620 inhabitants, of whom 2936 are ſlaves, and furniſhes very large timber.

DAVIEL, James, in *Biography*, a native of Barre, in Normandy, where he was born Aug. 11, 1696, ſtudied ſurgery, under his uncle at Rouen, and having completed his apprenticeſhip, he was ſent to the Hotel Dieu at Paris. The plague breaking out in 1719, at Marſeilles, he, with ſeveral other young ſurgeons, who had volunteered their ſervices, was ſent thither, furniſhed with regulations for their conduct, with the view of enabling them to eſcape the infection, and of giving ſuch aſſiſtance as art could afford to the afflicted with the diſeaſe. Daviel, who had the good fortune to eſcape being infected, had acquired ſo much credit for the intrepidity and humanity of his conduct, that, ſoon after the ſubſidence of the plague, he was appointed reader in anatomy, a poſt he continued to fill for twenty years. Having made the anatomy and diſeaſes of the eye, in a particular manner, the objects of his attention, he acquired ſo much reputation for his ſkill in performing the operation for the cataract, that perſons came to conſult him from all parts of the kingdom. He at firſt depreſſed, or couched the cataract, but not being able to ſucceed in that way, in one of his patients, he extracted the cryſtalline humour, and effected a complete cure. This was in the year 1747. The ſame year he removed to Paris, where his fame having preceded him, he is ſaid to have performed the operation, by the new method, on two hundred and ſix patients, and that it completely ſucceeded with one hundred and eighty two of the number. He was ſoon after made aſſociate of the academy of ſciences at Toulouſe, of the inſtitution of Boulogne, and of the royal academy of ſurgery at Paris. Daviel continued increaſing in reputation, until, by the failure of his health, he was incapable of attending the duties of his profeſſion. In 1760 he ſuffered a ſtroke of palſy; from that time his ſtrength declined, and in Sept. 1762, a return of the paralytic affection put an end to his life. Haller Bib. Surg. Eloy Dict. Hiſt.

DAVIES, John, born at Lanvaethley, in the iſland of Angleſey, in 1534, received his education at Oxford, where he reſided four years; but having taken his degree of bachelor in arts, he obtained leave of his friends to travel into Italy. He now attended diligently to the ſtudy of medicine, and having taken the degree of doctor in that faculty, at Sienna, he returned to his native country, and acquired conſiderable fame by his ſkill and ſucceſs in practice, which he continued to the year 1609, when he died. He left no profeſſional work, but he is ſaid to have occaſionally printed ſome poems, which have not ſurvived; and a work on the Italian and Engliſh language. Eloy Dict. Hiſt.

Davies, John, a learned Welſh divine, was born in Denbighſhire, and educated by William Morgan, afterwards biſhop of St. Aſaph. He finiſhed his ſtudies, and took the degree in arts at Jeſus college. In 1616 he took his degree of doctor in divinity, and was made canon of St. Aſaph. His character was held in high eſtimation for his deep and very accurate knowledge in the Greek and Hebrew languages, and for his acquaintance with ancient writings, and curious and rare authors. His principal works are, "Antiquæ Linguæ Britannicæ nunc communiter dictæ Cambro-Brittannicæ, a ſuis Cymræcæ, vel Cambricæ, ab aliis Wallicæ rudimenta," &c. 1621, 8vo. "Dictionarium Britannico-Latinum." 1632, folio. Among the MSS. in the Bodleian Library is preſerved a piece of Dr. Davies, entitled "Adagiorum Britannicorum Specimen." The doctor aſſiſted likewiſe William Morgan and Richard Parry, ſucceſſive biſhops of Landaff, in making the verſion of the Welſh bible, which was publiſhed in the year 1620. Gen. Biog.

Davies, Sir John, an eminent perſon, as a poet, lawyer, and political writer, was born as Chiſgrove, Wiltſhire, in 1570. He ſtudied at Queen's college, Oxford, and afterwards removed to the Temple in purſuit of the law. He was called to the bar in 1595, but on account of ſome miſconduct, occaſioned by the violence of his temper, he was expelled from that ſociety. He ſeems to have been fully aware of the raſhneſs of his conduct, and retired to Oxford, as well to correct the paſſion to which he was liable, as to devote his time to the muſes. In a poem entitled "Noſce Teipſum," he acknowledges his obligation to affliction in aiding the reformation of his temper:

> "This miſtreſs lately pluck'd me by the ear,
> And many a golden leſſon hath me taught;
> Hath made my ſenſes quick, and reaſon clear;
> Reform'd my will and rectified my thought."

By this piece he eſtabliſhed his reputation as a poet, and as a ſolid judicious thinker. In 1601, Mr. Davies very laudably made ſuch ſubmiſſion for his paſt conduct as reſtored him to his chambers in the Temple. In the ſame year he was choſen member of parliament for Corfe Caſtle, and took a ſpirited part in the debates reſpecting monopolies. On the acceſſion of king James, he was particularly noticed by his majeſty, as the author of "Noſce Teipſum;" and in 1603 he was ſent to Ireland as Solicitor General, and was ſoon after made attorney-general, and a judge of aſſize; and in 1607, the honour of knighthood was conferred on him. In Ireland he was extremely inſtrumental in conveying the benefits of equal laws to thoſe parts of the iſland which had hitherto been ſtrangers to them. On his return to England he laid before his ſovereign an account of all that had been done towards the civilization of Ireland, an object which he had much at heart, and which he purſued on going back moſt aſſiduouſly. In 1612 he publiſhed "A Diſcovery of the true Cauſes why Ireland was never entirely ſubdued and brought under Obedience of the Crown of England, until the Beginning of his Majeſty's happy Reign." This work was deemed extremely valuable, and it is remarkable that in the ſame year a parliament was convoked in Ireland, the firſt in that kingdom formed by a general repreſentation; and in this, Catholics as well as Proteſtants ſat, in almoſt equal numbers. Sir John Davies was

elected member for Fermanagh, and was chosen speaker in the house by the court party. Sir John, in his opening speech, was said to be guilty of much adulation toward the king, who had shewn him many tokens of his favour. In 1614, he published "A Declaration concerning the Title of the Prince of Wales," and in 1615, "Reports of Cases adjudged in the King's Courts of Ireland." To this volume is prefixed a very learned and eloquent eulogy on the common law of England, and a vindication of its professors. He soon after returned to England, and went several circuits as judge. He was now elected member of parliament for Newcastle-under-Line, and sat in the parliament of 1621. He died in 1626 in his fifty-seventh year, after having been lately appointed lord-chief-justice of England. The principal prose works of sir John Davies were published in one volume 8vo. 1786, under the title of "Historical Tracts," &c. Sir John Davies left two children, a son an ideot, and a daughter married to Ferdinando lord Hastings. Biog. Brit.

DAVIESIA, in *Botany*, a New Holland genus of Papilionaceous plants, with ten distinct stamens, named in honour of the Rev. Hugh Davies, F.L.S. of Beaumaris, one of the chief contributors in Welsh plants to Mr. Hudson's "Flora Anglica," as well as to the "Flora Britannica" and "English Botany" of Dr. Smith and Mr. Sowerby, and author of a paper, on four British Lichens, in the 2d vol. of the Linnæan Society's Transactions. Sm. Tr. of Linn. Soc. v. 4. 220. Ann. of Bot. v. 1. 506. Class and order, *decandria monogynia*. Nat. Ord. *Leguminosæ*, sect. 4. Juss.

Gen. Ch. *Cal.* campanulate, angular, in five various segments, without any appendages. *Cor.* papilionaceous, of five petals; standard inversely heart-shaped, broad, reflexed; wings shorter, obliquely obovate; keel rather shorter than the wings, of two petals, each with a tooth above, near the base. *Stam.* ten, enclosed in the keel; filaments awl-shaped, equal, distinct, ascending, conniving; anthers roundish. *Pist.* Germen superior, ovate, compressed; style ascending, awl-shaped, reaching to the anthers; stigma simple, acute. *Peric.* Legume compressed, of one cell, and two cartilaginous elastic valves. *Seed* solitary, kidney-shaped, compressed, much smaller than the cavity.

Ess. Ch *Calyx* angular, simple, five-cleft. *Corolla* papilionaceous. *Style* awl-shaped. *Stigma* simple, acute. *Legume* compressed. *Seed* solitary.

Sp. 1. D. *acicularis*. Sm. in Sims and Konig's Annals of Bot. v. 1. 506. "Leaves linear, revolute, pungent, straight, rough, with minute teeth. Flowers axillary, solitary." *Stem* shrubby, branched, rigid. *Leaves* sessile, scattered, numerous, linear, narrow, an inch long, revolute, rough to the touch, each tipped with a sharp spine, with a very minute pair of awl-shaped stipulas at their base. *Flowers* axillary, solitary, on very short stalks, bearing a few concave, roundish, smooth bracteas. *Calyx* divided half way down into five acute, nearly equal, teeth. *Petals* yellow, variegated with crimson. It is almost peculiar to this genus, that, in drying, the yellow turns white, and the crimson becomes a dull purplish brown. *Legume* semi-ovate, sharp-pointed, perfectly compressed, about four lines long, of a rich polished chesnut-colour. A native of New South Wales, near Port Jackson. John White, M.D. 2. D. *incrassata*. "Leaves linear-wedge-shaped, compressed, vertical, oblique, thick, spinous. Flowers axillary, solitary." Sm. MSS. Whole shrub of a thick and seemingly succulent habit. *Leaves* perfectly decurrent, scattered, vertical, rough to the touch, compressed, recurved, linear, but dilated into a sort of angle at the upper edge, by which they become wedge-shaped. *Stipulas* wanting. *Flowers* few, yellow. Found at King George's Sound, on the west coast of New Holland, by Mr. A. Menzies. 3. D. *ulicina*. Sm. in Ann. of Bot. v. 1. 506. Donn. Cant. 76. (D. ulicifolia; Andr. Repos. t. 304.) "Leaves lanceolate, flat, pungent, straight, smooth. Flowers axillary, solitary." Sm. MSS. A rather more humble and more bushy shrub than either of the former, with sessile, not decurrent, small, lanceolate, smooth leaves. *Flowers* copious, on small, bracteated, solitary stalks, yellow, with a crimson crescent-shaped spot in front of the standard, and a stain of the same hue at its back, which style of colouring seems universal in this genus, as far as we have seen, as likewise frequently in others of the same natural tribe. *Pod* ovate, pointed, flattened. Brought from Port Jackson, and long ago raised from seed by several cultivators about London, being the only real species of *Daviesia* cultivated in Britain. It thrives in sandy peat earth, with the shelter of a green-house, but must be sparingly supplied with water in winter. It flowers plentifully in May or June. 4. D. *reticulata*. "Leaves lanceolate, pungent, reticulated with veins on both sides. Stipules in pairs, within the insertion of the leaves. Flowers axillary, solitary." Sm. MSS. A small branching shrub, of which we have seen only a dried specimen, gathered by Mr. Menzies near King George's Sound, New Holland. Its numerous *leaves*, rather above half an inch long, are most elegantly reticulated on both sides with fine yellow interbranching veins. *Stipulas* intrafoliaceous, or standing within the insertion of each leaf, a very remarkable character, this being the only species, except the first, in which these organs have been observed at all, and they here approach greatly to the nature of the stipulas of the genus *Puttenæa*, as also do the bracteas of the present plant, being silky at their backs, and closely imbricated round the base of the almost sessile flower. The *calyx*, however, decides the genus, being angular, and destitute of appendages. The *legume* has not been seen. 5. D. *squarrosa*. Sm. in Ann. of Bot. v. 1. 507. "Leaves heart-shaped, pungent, reflexed, rough in the margin. Flower-stalks axillary, single-flowered, mostly solitary." A native of the country not far from Port Jackson, New South Wales, whose thick woody perennial *root* throws up numerous, slender, wand-like, furrowed, rough, slightly branched *stems*, two feet high, clothed from top to bottom with numerous, small, scattered, sessile, reflexed, heart-shaped, *leaves*, whose edges are thickened and rough, and their points spinous. From the bosom of each leaf springs one, rarely two, slender, smooth, simple *flower stalks*, about as long as the corresponding leaf, with a few concave, roundish *bracteas* about the lower part. *Flowers* solitary, smaller than in any of the former, but apparently of the same colours, with an obscurely two-lipped calyx. 6. D. *umbellulata*. Sm. in Ann. of Bot. v. 1. 507. "Leaves lanceolate, flat, pungent. Flower-stalks axillary, solitary, each bearing an umbel of about four flowers. Calyx truncated." Allied to the last in habit, and a native of the same country. *Leaves* much longer, lanceolate, spreading, nearly smooth. *Flower-stalks* shorter than the leaves, bearing a few little scattered *bracteas*, and an umbel of about four flowers, with several larger bracteas at its base. These *flowers* differ from those of D. *squarrosa*, in having the upper lip of the *calyx* singularly truncated, and not cloven. The calyx in this genus is a part of the fructification which most differs among species otherwise the nearest akin. 7. D. *corymbosa*. Sm. in Ann. of Bot. v. 1. 507. "Leaves linear-oblong, flat, unarmed. Flower-stalks axillary, in pairs, corymbose, many-flowered. Calyx regular." Gathered by colonel Paterson, near Hawkesbury river, New South Wales. It is larger than the last. *Leaves*

five or ſix inches long, reſembling thoſe of ſeveral *Mimoſæ* of New Holland, almoſt lanceolate, ſlightly oblique, entire, ſmooth, acute, but not tipped with a ſpine. *Flower-ſtalks* axillary, in pairs, corymboſe, rather unequal, one being earlier than the other, both ſhorter than the leaf. *Bracteas* one under each partial ſtalk, and ſome ſcattered. *Flowers* numerous, their calyx-teeth as nearly equal and regular as they can be in a papilionaceous flower. 8. D. *cordata*. "Leaves heart-ſhaped, claſping the ſtem, reticulated with veins. Flower-ſtalks axillary, cluſtered, corymboſe, many-flowered. Calyx truncated." Sm. MSS. This ſpecies is very remarkable for its large heart-ſhaped *leaves*, three or four inches long, claſping the very angular branches. They are firm and coriaceous, marked with a prominent net-work of innumerable veins. *Flower-ſtalks* corymboſe, unequal, four or five from the boſom of each leaf, bracteated, many-flowered. Two upper teeth of the *calyx* combined and truncated as in the 6th ſpecies. This is a native of the country near King George's Sound, and is one of the largeſt of its genus, having the habit of ſome great *Borbonia* or *Crotalaria*. 9. D. *alata*. "Stem leafleſs, winged. Umbels lateral. Calyx and bracteas fringed." Sm. MSS. A very remarkable ſpecies, found near Port Jackſon, but few ſpecimens have been brought to Europe. The adult *ſtem* is triply winged throughout, the wings ſmooth, entire, even, about a line broad, tapering down to the baſe of each branch, and only interrupted here and there by buds, ſcattered alternately along the branches. *Umbels* ſolitary from ſeveral of the upper buds, on ſhort bracteated ſtalks, moſtly five-flowered. Immediately under the rays of the umbel ſeveral larger bracteas, very remarkably jagged or fringed, and the elongated, nearly equal, teeth of the *calyx* are fringed in the ſame manner, which is one of the ſtriking peculiarities of this plant. 10. D. *juncea*. "Stem leafleſs, round, furrowed, naked. Umbels lateral. Calyx and bracteas entire." Sm. MSS. Brought by Mr. Menzies from King George's Sound. Its ruſhy habit, ſomewhat like *Spartium junceum*, the *ſtem* being round, furrowed, roughiſh, without any wings, renders it abundantly diſtinct from the laſt, to which it is otherwiſe next akin. The *bracteas* and *calyx*, moreover, are not at all fringed; the former are peculiarly concave and ribbed; the latter nearly regular, indeed, but the five teeth are ſhort, their edges very minutely downy only. *Petals* of both theſe ſpecies, as far as can be judged from dried ſpecimens, of the ſame colours as in the generality of the genus.

Propagation and Culture.—All the ſpecies are ſhrubby, and, probably, like papilionaceous plants in general, beſt raiſed from ſeeds, which, in this tribe may, for the moſt part, be kept long, and tranſported to a great diſtance. It is rather remarkable that ſeeds of D. *ulicina* only, as far as we are informed, have ſucceeded in Europe. Of the cultivation of this we have already ſpoken. It is ſaid alſo to be capable of being multiplied by cuttings, which is needleſs, as its ſeeds ripen well in our green-houſes. S.

DAVIESIA *denudata*. Venten. Choix. t. 6. See VIMINARIA *denudata*.

DAVILLA, HENRY CATHERINE, in *Biography*, a celebrated Italian hiſtorian, was born in the year 1576, in Padua. His father held a conſiderable poſt in the kingdom of Cyprus, when the iſland was captured by the Turks, by which event he was reduced to poverty. At an early age Henry was taken into France, and was ſoon after made a page at court. He entered into the military ſervice, and gave ſome ſignal proofs of courage, in which his life was often in imminent danger. In 1599, he returned to Padua at the deſire of his father, and, upon his death, Henry engaged in the ſervice of the Venetian republic, by which he was employed in duties of the higheſt import; and in theſe acquitted himſelf ſo well, and ſo much to the ſatisfaction of the ſenate, that he was permitted to ſtand next the doge, as his anceſtors, the conſtables of Cyprus, had formerly done. Notwithſtanding his various active employments, Davilla found time for literary purſuits: in 1631 he publiſhed in Italian, his "Hiſtory of the civil Wars of France." It comprehends the events of 40 years, *viz.* from the death of Henry II. to the peace of Vervins, in 1598, and is highly eſteemed for the perſpicuity of the ſtyle and arrangement, and for the fidelity and accuracy of the facts. His reflections are judicious and ſenſible, and his narrative is pleaſant and lively. In the following year he was appointed to the command of Crema, and ſet out from Venice on his journey: an unfortunate diſpute aroſe between him and the perſon who was bound to furniſh him with carriages, which terminated in the death of Davilla, who was ſhot dead by his brutal opponent in the preſence of his wife and children. Some other perſons were killed and wounded in the affray; but one of his ſons revenged the death of his father on the murderer. The beſt editions of Davilla's hiſtory are that of the Louvre in 1644; of Venice in 1733; and that printed in London in 1755. It has been tranſlated into ſeveral modern languages. Moreri.

DAVIS, JOHN, an able navigator, who has given name to a ſtrait leading to Baffin's bay, was born at Sandridge, near Dartmouth. He ſhewed at a very early age a ſtrong diſpoſition for a maritime life, and by his great aſſiduity, after he was admitted to follow the bent of his inclination, he acquired great reputation. In 1585 he was entruſted with the conduct of an expedition, for exploring a north-weſt paſſage from America to the Eaſt Indies. He proceeded to Greenland, and after paſſing the moſt ſoutherly point, he came to that ſtrait which has ever ſince borne his name. Having ſailed up the ſtrait thirty leagues or more, he returned to England. In a ſecond expedition he explored the coaſts and inlets which he had only ſeen before. And in a third, in 1587, he entered the ſtrait again, and ſailed as far as lat. 73°: he then ſailed weſtward till he fell in with American land; from the circumſtances attending theſe voyages he became ſanguine in the expectation of finding a paſſage; but the threatened Spaniſh invaſion obliged him to return home. He ſailed, 1591, to the South-ſeas, as captain of the Deſire, under the command of Mr. Cavendiſh, by whom he was charged with miſconduct in deſerting him. After this Mr. Davis made five voyages to the Eaſt Indies, in the capacity of pilot. During the laſt he loſt his life, in an engagement with ſome Japaneſe, on the coaſt of Malacca. This happened at the cloſe of the year 1605. He left behind him an account of ſome of his voyages, and other tracts. Biog. Brit.

DAVISBURG, in *Geography*, a poſt-town in Chriſtian county, Kentucky, 816 miles W. of Waſhington.

DAVIS's *Cove*, a cove on the weſt coaſt of the iſland of Jamaica; two miles N. of Green-iſland harbour.

DAVIS's *Inlet*, a river or arm of the ſea, on the E. coaſt of Labrador, the mouth being ſituate in N. lat. 56° 20'. W. long. 60° 10'.

DAVIS's *Land*. See EASTER *Iſland*.

DAVIS's *Quadrant*. See BACK-STAFF.

DAVIS's *Strait*, in *Geography*, a narrow ſea which ſeparates the north main of America from the weſtern coaſt of Greenland, running N. W. from Cape Farewell, N. lat. 60°, to Baffin's bay, in N. lat. 80°, and extending to W. long. 75°, where it communicates with Baffin's bay, which lies to the north of this ſtrait, and of the north main, or James's

iſland. It is called Davis's ſtrait, becauſe it was diſcovered in 1585 by Mr. John Davis, an experienced navigator, who viſited the weſtern coaſt of England, and explored this narrow ſea, improperly ſo denominated, becauſe it is as wide as the Baltic.

Davis *Town*, a town of America, in the diſtrict of Maine, and county of Lincoln, containing 308 inhabitants.—Alſo, a town in the ſame diſtrict, and county of Hanerek, containing 269 inhabitants.

DAVIT, in *Ship-rigging*, denotes a ſhort boom fitted in the fore-channel, and uſed as the arm of a crane to hoiſt the flukes of the anchor clear of the ſhip's ſide, till high enough to lie on the gun-wale, and faſtened by the ſhank painter.

Davit-*Guys*, are ropes uſed in the rigging of ſhips, which have an eye ſpliced in one end to the circumference of the davit-head; they are ſerved with ſpun-yarn over the ſplice, and whipt with ſpun-yarn at the other end.

Davit-*Rope*, denotes the laſhing which ſecures the davit to the ſhrouds, when out of uſe.

DAULI, in *Geography*, a town of South America, in the audience of Quito, and juriſdiction of Guayaquil.

DAULIA, in *Ancient Geography*, a town of Macedonia, in the canton of Eordetes, and near Scampis. Ptolemy.—Alſo, a country of the Phocide, which includes another diſtrict called *Tronis*.

DAULIS, a town of the Phocide, at ſome diſtance S.E. from Delphi. Homer, Pauſanias, and Steph. Byz. name it Daulis; but Polybius calls it Δαυλις, Daulium. According to Pauſanias, this town was very populous, and its inhabitants were the largeſt and moſt robuſt of any in the Phocide territory. At Daulis was a temple of Minerva, with two ſtatues of this goddeſs. It was more anciently called *Anaöris*. On the ruins of this town is a village, containing 40 or 50 houſes; and in this village is a river, which ſprings among the rocks of Parnaſſus, and which the people of the country call *Mauroneri*, *i. e.* black water, ſuppoſed to be that which the Greeks call Melas.

DAULSEN, in *Geography*, a town of Germany in the circle of Weſtphalia, and county of Verden; 4 miles N. N.E. of Verden.

DAUMA, a kingdom of Africa, in Negroland, with a town of the ſame name. N. lat. 8°. W. long. 16° 24′.

DAUMAZAN, a ſmall town of France, in the department of the Arriége, 12 miles N. W. of Pamiers.

DAUN, Leopold, Count of, in *Biography*, a celebrated general in the Auſtrian ſervice, was born in the year 1705, and intended by his father, who was an imperial general, for the church. The young man, however, was of an active turn, and deſirous of treading in the ſteps of his parent, obtained firſt an admiſſion among the knights of Malta. In the year 1740, he was made a colonel, and diſtinguiſhed himſelf in the war which Maria Thereſa ſuſtained in defence of her hereditary ſucceſſion. In the war of 1756, he was known and diſtinguiſhed as the moſt formidable antagoniſt of the king of Pruſſia: in the following year he entirely defeated the monarch, and was, on that account, highly eſteemed by the empreſs-queen. In 1758, he ſaved Olmutz by a ſeries of very judicious movements, and afterwards engaged with, and again defeated, the Pruſſian ſovereign. In 1760, when Dreſden was attacked by the king, Daun at reſt compelled him to relinquiſh his attempt, but he was, at length, owing to a ſevere wound, defeated, and obliged to quit the field. He died at Vienna in 1766, highly eſteemed as well for his private virtues, as for his military talents. Through the whole of life he was indefatigable in every thing entruſted to him: he evinced on almoſt every occaſion conſummate ſkill; but has been thought defective in the ſpirit of enterprize and deciſion, which enables a general to ſeize and improve a favourable moment. Nouv. Dict. Hiſt.

Daun. See Dauhn.

DAUNIA, in *Ancient Geography*, a country of Italy in Apulia. Pliny ſays, that it lay N. W. of Peucetia, and that it was bounded to the eaſt and north by the Adriatic ſea, to the weſt by Biſerno, the country of the Samnites and that of the Hirpini, and to the ſouth by mount Cervago, which ſeparated it from Peucetia. Its chief towns were Sipuntum, Arpi, Luceria, &c. Strabo ſays, that thoſe people were called Daunians by the Greeks, whom the Latins called Apulians.

DAUNUS, *Caravalle*, a torrent of Italy, which gave name to the country in its vicinity. Horace mentions the extreme heat of this country.

DAVOS, Davas, or Tafaas, in *Geography*, formerly a juriſdiction of the league of the ten juriſdictions, in the country of the Griſons, in Switzerland, is at preſent a diſtrict of the canton of the Griſons in the Helvetic republic. It is a long plain, a quarter of a mile broad, and gradually riſing into hills which terminate in high mountains. A clear murmuring ſtream flows through the midſt of the plain, with a gentle but lively courſe. The whole diſtrict is divided into five pariſhes, and the inhabitants are Proteſtants. The houſes, however, are ſo diſperſed as not even to form one ſingle village, properly ſo called. Near the church of St. John is a ſmall cluſter of eight or ten houſes; in the other parts the cottages are thickly ſtrewed over the plain. There are two lakes abounding in fiſh, and ſome mines of ſilver, copper, and lead ore. The pariſh of Sartig has a mineral ſpring. The country produces oats, rye, large quantities of rich paſture, yielding yearly two crops of hay. The mountains are overſpread with foreſts of fir and larch, intermixed with meadows. Above them tower the rugged Alps.

Grazing is the principal occupation of the inhabitants of the diſtrict of Davos. They alſo keep pack-horſes for the tranſport of the goods which paſs through their country from Germany and Switzerland into Italy, and they manufacture plenty of wooden wares. They ſpeak German, but their pronunciation is as defective as that of the inhabitants of the republic of the Valais.

The general diet of the Griſons uſed to be held at Davos. Coxe's Switzerland. Dictionnaire de la Suiſſe.

DAUPHIN, Dolphin, in *Aſtronomy*. See Delphinus.

Dauphin, in *Conchyliology*, the name of a ſpecies of ſhell-fiſh. It is one of the round-mouthed ſnails, or cochleæ lunares; and is ornamented with rows of indented eminences, on all the turns of the ſhell.

Dauphin, in *Geography*, an iſland in the north part of the gulph of Mexico, at the mouth of the river Mobile, five miles from Maſſacre iſland, with a ſhoal every where between them; which iſlands were ſuppoſed formerly to have been but one, and to have been known by the name of Maſſacre, ſo called by M. d'Ibberville, from a large heap of human bones, found by him at his landing. Dauphin iſland is about five leagues long, but narrow, and very barren. At the weſt end, for a diſtance of between three and four miles, is a narrow ſlip of land, with ſome dead trees; the reſt is covered with thick pines, which come cloſe to the water's edge, on the E. ſide, forming a large bluff. The French attempted a ſettlement here, and the cultivation of tobacco, which was ſaid to be equal to that of Virginia. On the S. ſide of the iſland there are remains of an old French poſt, and of ſome old houſes of the natives. In 1719 the Spaniards made a fruitleſs attempt to take it, during the ſpace of four days. N. lat. 30° 15′. W. long. 88° 10′.

DAUPHIN, a county of America, in the ſtate of Pennſylvania, formerly contained in that of Lancaſter, but erected into a ſeparate county in 1785. Its form is triangular; it is ſurrounded by the counties of Mifflin, Cumberland, York, Berks, and Northumberland, and it contains 586,400 acres. It is divided into nine townſhips, the chief of which is Harriſburg; the number of its inhabitants is 22,270. About one half of this county is cultivated; but the northern part is very rough and mountainous. In ſeveral of the mountains is found abundance of iron ore of the beſt quality; and a furnace and forge have been erected for the manufacture of pig, bar iron, &c. The firſt ſettlers were Iriſh emigrants, who were afterwards joined by a number of Germans.

DAUPHIN, a name given in the reign of Henry IV. of France to the iſland of Madagaſcar.

DAUPHIN *Creek*, a creek at the S.E. extremity of Madagaſcar, near fort Dauphin.

DAUPHIN *Fort*, a fort at the ſouth-eaſtern extremity of the iſland of Madagaſcar, in the province of Cercanoſſy. The diſtrict of the iſland about this fort is well peopled. Almoſt every village ſtands on an eminence, encompaſſed by two rows of ſtrong paliſades. Within ariſes a parapet of earth, four feet high; and large, ſtrong bamboos, placed at the diſtance of five feet from each other, form a kind of fortification which defends theſe villages, which, in ſome caſes, are ſurrounded by a foſſe, ten feet broad, and ſix feet deep. The dwelling of the chief is called "donac," and this compriſes three or four large houſes, incloſed by a particular fence. Here the chief always reſides, with his wives and children. Slaves keep guard night and day at the doors of the donac. Fort Dauphin was burnt down in the year 1655; and not rebuilt till 1663. S. lat. 25° 15′. E. long. 69° 5′. See MADAGASCAR.—Alſo a juriſdiction, fort, and ſea-port town in the N. part of the iſland of St. Domingo; containing 5 pariſhes.—Alſo a fort in the iſland of Cape Breton.

DAUPHIN *River*, a river of upper Canada, which runs into lake Winnipeg on the W. ſide, at the head of Martin's bay. N. lat. 52° 15′.

DAUPHIN is the title which the eldeſt ſons of the kings of France, and preſumptive heirs to the crown, bore, for nearly 450 years, till the year 1791, when, in order to aboliſh every the moſt remote veſtige of feodality, the national aſſembly decreed its ſuppreſſion, and ſubſtituted the appellation of *Prince royal*.

Charles Louis, the laſt dauphin, ſon of Louis XVI. and Maria Antoinetta of Auſtria, born on the 27th of March 1785, was firſt named duke of Normandy, and took the title of dauphin only after the death of his elder brother Louis Joſeph Xavier Francis, in 1790. The rejoicings which took place in France at the birth of this laſt prince in 1781, evinced ſuch a ſincere and enthuſiaſtic attachment to the royal family, that it forms the moſt ſtriking contraſt with the events which took place eleven years after. Charles Louis did not enjoy the new title of prince royal much longer than he had enjoyed that of dauphin. On the 11th of Auguſt, 1792, he was impriſoned at Paris with his royal parents in the Temple. On the 24th of September of the ſame year, the abolition of royalty in France was decreed by the convention; and after the execution of the unfortunate monarch his father, which took place on the 21ſt of January, 1793, the young prince continued a priſoner till the middle of the year 1795, when his unjuſt and cloſe confinement probably haſtened his death. His complaint is reported to have been of the ſcrofulous kind, and it does not appear that medical aid was denied him; but his comforts had been ſhamefully abridged, and his education abſolutely neglected, and moſt wilfully perverted. He expired on the 9th of June 1795, at the age of ten years two months and thirteen days. The writers of the royaliſt party in France, conſidering this prince as lawful heir to the throne, ſtyled him king ever after the demiſe of his ill fated parent, by the name of Louis XVII.; which ſee.

The title of dauphin was firſt borne in France about the year 1345, by Philip, a younger ſon of Philip de Valois, to whom Humbert III. dauphin of the Viennois, had ceded his dominions, conſiſting chiefly of the dauphiné. However, after Charles V. ſurnamed the *Wiſe*, the kings of France never conferred the appellation of dauphin on any one, but their eldeſt ſons, and preſumptive heirs of the crown. The title itſelf took its riſe about the year 1120 in Guigues IV. ſon of Guy or Guigues the Fat. Being of a warlike diſpotion, he choſe a dolphin for the creſt of his helmet; and having ſignalized himſelf by ſome exploit, he was probably diſtinguiſhed by the name of his armorial bearings, and tranſmitted this name as a new diſtinction to his deſcendants.

The ſeigneurs, or lords, of Auvergne, have likewiſe borne the appellation of dauphin; but the dauphins of Auvergne had it not till a good while after thoſe of the Viennois, and even received it from them. The manner was this: Guy VIII. dauphin of Viennois, had by his wife Margaret, daughter of Stephen, earl of Burgundy, a ſon and two daughters. The ſon was Guy IX. his ſucceſſor. Beatrix, one of the daughters, was married to the count d'Auvergne, who, according to Blondel, was William V. or rather, as Chorier and others hold, Robert VI. father of William V. This prince loſt the greateſt part of the county Auvergne, which was taken from him by his uncle William, aſſiſted by Louis the Young; and was only left maſter of the little canton whereof Vodable is the capital. He had a ſon whom he called Dauphin, on account of Guy, or Guigues, his uncle by the mother's ſide. From his time his ſucceſſors, holding the ſame petty canton of Auvergne, ſtyled themſelves dauphins of Auvergne, and bore a dolphin for their arms.

DAUPHIN, in *Mechanics*, &c. See DOLPHIN.

DAUPHINS, or DELPHINS, in *Literary Hiſtory*, a name given to the commentators on the ancient Latin authors, who were employed by order of Louis IV. of France, for the benefit of the prince, under the care and direction of M. de Montauſier his governor, Boſſuet and Huet his preceptors. They were thirty-nine in number.

DAUPHINE′, in *Geography*, one of the ſouth-eaſtern provinces of France, before the revolution of 1789. It contained the following counties, *viz.* the Gréſivaud and the Viennois, which form now the department of the *Iſère*, which ſee; the Valentinois and the Diois, which conſtitute at preſent the department of the *Drôme*, which ſee; and the Gaſſençais, Embrunais, and Briançonnais, which form now the department of the *Hautes Alpes*, which ſee. Grenoble was the capital of the whole province. The territorial extent of the Dauphiné was eſtimated at 1006 ſquare leagues, and its population at 804,800 individuals, or 800 inhabitants per ſquare league.

DAUSARA, or DOYSARA, *Dauſar*, in *Ancient Geography*, a town of Aſia, in Meſopotamia, ſeated upon the banks of the Euphrates, nearly S. of Edeſſa, and S.E. of Nicephorium.

DAUSENAS, in *Geography*, a town of the duchy of Courland; 16 miles W.S.W. of Seilburg.

DAUTONA, in *Ancient Geography*, a town of Higher Pannonia, 24 miles from Siſcia, according to the Itinerary of Antonine.

DAUW, in *Geography*, a town in the ſouthern part of the iſland of Celebes.

DAVYING, in *Agriculture*, a term applied provincially to

to the getting of marl out of the face of the cliffs on the ſea coaſts, where it is drawn up by a ſort of wince.

DAW, in *Ornithology*. See CORVUS *Monedula*: called alſo the jackdaw.

DAW, *Surinam*. See CORVUS *Surinamenſis*.

DAW, *Black and Yellow*. See ORIOLUS *Perſicus*.

DAWEL-CORONDE, in the language of the Ceyloneſe, drum cinnamon. This is called in Low Dutch, trommel cancel. The reaſon of the name is, that the wood of the tree which affords this ſpecies, when dried, is light and tough, and is uſed to make drums of. The bark is taken off while the tree is growing, and is of a pale colour. It is a very bad kind of cinnamon, and is very rarely ſold as ſuch; but the natives uſe it in medicine.

DAWES, RICHARD, in *Biography*, was born in 1708, and received the early part of his education at Market-Boſworth, Leiceſterſhire, under Dr. Blackwall, author of the "Sacred Claſſics." The higher branches of ſtudy he purſued at Emanuel college, Cambridge, where he took his degrees, and where he exhibited much enmity and rancour againſt the learned Bentley, whoſe knowledge in the Greek he affected to treat with contempt. About the year 1738, he was appointed maſter of the free grammar-ſchool at Newcaſtle-on-Tyne, to which office was annexed the maſterſhip of St. Mary's hoſpital in that town. The profound learning of Mr. Dawes did not qualify him for the diſcharge of the laborious duties of a ſchool-maſter: his temper was too irritable, and his character was ſo ſingular, that he was perpetually involved in quarrels. In about ten years he was perſuaded to reſign both places, and to accept, in exchange, an annuity of 80*l. per ann.* with which he retired; making his chief amuſement rowing a boat on the river near his houſe. He died in 1766; but as a critic and a ſcholar he had laid a broad baſis for permanent reputation. His "Miſcellanea Critica," which was publiſhed in 1745, and which has ſince been republiſhed with additions, by Mr. Burgeſs of Oxford, "contained," ſays his biographer, "a collection of grammatical remarks on various Greek authors, particularly the tragedians and Ariſtophanes; intended as a ſpecimen of what he meant to perform in an edition of all the Attic poets, with Homer and Pindar." Biog. Brit.

DAWES, SIR WILLIAM, a reſpectable prelate of the church of England, was born in the year 1671, near Braintree, in Eſſex. He received his grammar-learning at Merchant Taylors' ſchool, in London, where he made a very rapid progreſs in the learned languages; and in 1687 he was elected ſcholar of St John's college, Oxford, of which ſociety he was, in two years, made fellow. As ſoon as he ſucceeded to his father's title and eſtate, he left Oxford, and entered himſelf a nobleman in Catharine-hall, Cambridge, where he took his degree of M.A. Being at this time too young to obtain holy orders, he ſpent ſome time in viſiting different parts of his native country; and when he attained to the age of twenty-five he was ordained deacon and prieſt, and, by the royal mandate, created doctor in divinity, in order to be qualified for the maſterſhip of Catherine-hall, to which he was unanimouſly called, in 1696. To this college he was afterwards a liberal benefactor. In the ſame year he was appointed chaplain in ordinary to the king, and vice-chancellor of the univerſity. Sir William was, in the year 1698, collated to the rectory and deanery of Bocking, in Eſſex, where he obtained the reſpect and affectionate regards of all claſſes of the people. After the acceſſion of queen Anne, ſir William was appointed her chaplain, and became a favourite at court, and would have been made biſhop of Lincoln, in 1705, but for the interference of ſome perſons who had taken offence at a ſermon which he had preached on the 30th of January. But in two years after he was appointed to the biſhopric of Cheſter; and in 1713 to the archbiſhopric of York, in which he continued, an ornament to his profeſſion, till the year 1724, when he died, full of honour and eſteem. He was reckoned the moſt popular preacher of the day. His works were collected, and publiſhed in 3 vols. 8vo. 1733; to which is prefixed a life of the author. Biog. Brit.

DAWFUSKEE, in *Geography*, an iſland on the coaſt of South Carolina, which forms the N.E. ſide of the entrance of Savannah river, and S.W. ſide of the entrance of Broad-river, and admits of an inland communication between the two rivers.

DAWIDGRODEK, a town of Lithuania, in the palatinate of Brzeſc; 56 miles E. of Brzeſc.

DAWLISH, called in domeſday-book *Doulis*, is a delightful maritime village in the county of Devon, England. The name is derived from its ſituation, *Dol-is*, a compound word, ſignifying, a fruitful mead in a pleaſing dell. On the land ſide, it is nearly ſurrounded by lofty hills of varied features; and on the eaſtern ſide, the ſea, with the bold over-hanging cliffs, furniſhes ſtriking effect to its romantic ſcenery. Dawliſh formerly was an inconſiderable place, merely a cove, and inhabited by a few fiſhermen; but ſince ſea-bathing has become faſhionable, it has riſen into conſequence, as a reſpectable watering-place. For the accommodation of the viſitors, a handſome row of buildings has lately been erected on the ſtrand, and numbers of houſes in various parts of the village. This part of the Engliſh coaſt is not only inviting by its pleaſing ſcenery, but alſo much eſteemed for the ſalubrity and mild temperature of the air.

About one mile weſt from Dawliſh is Luſcombe-houſe, the ſeat of Charles Hoare, eſq. This is an elegant modern manſion, erected from deſigns by Mr. Naſh, architect, who has endeavoured to unite in the plan, the convenient and comfortable, with the beautiful and pictureſque. The grounds ſurrounding the houſe conſiſt of a ſucceſſion of hill and dale; to the weſt appears the ſteep acclivity of Haldon-hill; to the eaſt, the tower of Dawliſh church; and in the diſtant view, the foaming waters of the Engliſh channel. Beauties of England and Wales, vol. iv.

DAX, or anciently, *Acqs*, *Aquæ Tarbellicæ*, a very ancient town of France, chief place of a diſtrict of the ſame name in the department of the Landes, ſituated on the left ſhore of the Adour, 30 miles N.E. of Bayonne, as many S. by W. of Bourdeaux, 42 of Aire, and 564 S. by W. of Paris. It was, in old times, the principal city of the Tarbellians, a nation celebrated among the Aquitanians; but there is not a veſtige remaining of its antique ſplendour, except a large and deep baſon in the middle of the place, conſtantly filled with ſmoking and almoſt boiling water, which forms a rivulet that flows into the Adour.

Until the 8th of April 1802, Dax was the ſee of a biſhop under the archbiſhop of Bourdeaux. It has now a ſub-prefect, two courts of juſtice, and a regiſter-office, and is one of the 84 maritime diſtricts.

Dax is chiefly remarkable for its numerous mineral ſprings, the four moſt famed of which are on the weſt ſide of the town; three ſerve for bathing, and the fourth for drinking. The water is clear, pellucid, almoſt taſteleſs, and ſo hot that it raiſes the thermometer to 56 degrees. According to Mr. Sécondat's analyſis, the water of Dax contains only a very ſmall quantity of muriat and ſulphat of lime; and it appears certain that its efficacy is leſs to be attributed to the ſaline matters which it contains than to its natural heat, which it preſerves for a long time. The water of Dax ought therefore to be uſed at the ſpring, or ſoon after it has come from

the ſpring. It is preſcribed in caſes of rheumatiſm and gout, and is then uſed both externally and internally.

Dax contains 4398 inhabitants; its canton has an extent of 380 kiliometres, 25 communes, and a population of 13,991 individuals. The whole diſtrict reckons 8 cantons, 112 communes, a territorial extent of 2415 kiliometres, and 77,796 inhabitants. It produces corn, wine, and wood. Its principal trade is in deals, roſin, tar, wheat, wine, and brandy. Herbin. Statiſtique de la France.

DAXABON, Dajabon, or *Dababon*, called by the French *Laxabon*, a town and ſettlement of Spaniards, on the line between the French and Spaniſh diviſions of the iſland of St. Domingo. It was ſettled to prevent ſmuggling when the Spaniards had their ſhare of the iſlands. It is bounded E. by the territory of St. Yago, N. by the extremity of the bed of the great Yaqui and the bay of Manceniila, and W. by the river and little iſland of Maſſacre. It contains about 4000 perſons. The town is ſituated 400 fathoms from the E. bank of Maſſacre river, more than 80 leagues N.W. of St. Domingo, and 28 W. of St. Yago. N. lat. 19° 32′. W. long. from Paris 74° 9′.

DAXBERG, a town of Germany in the archduchy of Auſtria; 2 miles W. of Efferding.

DAXENBACH, or Taxenbach, a ſmall town of Germany in the grand duchy of Saltzburg, with an old caſtle on the river Saltza.

DAXIMONILIS, in *Ancient Geography*, a country of Pontus, ſituated towards the weſt, and watered by the river Seylax.

DAY, or Bay, in *Architecture*, one of the lights or compartments between mullion and mullion, in the great windows of the pointed ſtyle of architecture. The Saxons and early Normans built plain arched windows of a moderate proportion, as to height and width, without any mullions. But when the pointed arch was introduced, about the reign of Henry II., and the windows became long and narrow, in the form of a lancet, it was ſoon found neceſſary to place two of them together, in order to tranſmit a ſufficient quantity of light. This ſuggeſted the ſingle mullioned window with two days or bays to it. This form ſoon gave way in the larger windows to double mullions, with three days; and as architecture enlarged its dimenſions and multiplied its ornaments, particularly in the grand eaſtern and weſtern windows of cathedrals, we afterwards find theſe conſtructed with five, ſeven, and even nine principal compartments, together with an infinity of tracery-work, quatrefoils, catharine-wheels, and other ornaments. At length, in the time of Henry VIII. and his children, architects returned to the point from which they had firſt ſet out, and built plain windows without any ſtriking ornaments or diviſions.

Day, in *Aſtronomy*, a portion of time equal to that which elapſes between two ſucceſſive tranſits of the ſun over the meridian.

The word day, in the ordinary language of ſociety, is often uſed in contradiſtinction to night, without any very accurate limit being affixed to either.

Aſtronomers likewiſe conſider the day in both theſe ſignifications, but endeavour to define the term more exactly.

The *aſtronomical or ſolar day* is the interval included between two ſucceſſive noons: Noon being defined, the preciſe moment when the centre of the ſun is on the meridian. This interval has been moſt uſually adopted by civilized nations, as the true length of the day.

The aſtronomical day begins at noon, and the 24 hours into which it is divided are counted on to the following noon; but the civil day uſed by us begins at midnight, and the twelve hours are repeated twice over. Thus February 10th, 19^h reckoned aſtronomically is, according to the mode adopted in ſociety, Feb. 11th, 7^h.

From the earlieſt times men have exerted their invention to imitate and ſubdivide this period by mechanical contrivances; and ſo unexpectedly fertile have been the reſources of human ingenuity, that the original model has been ſurpaſſed in regularity, and aſtronomers have been obliged again to have recourſe to nature, to find a more uniform ſtandard to which our chronometers ſhould be referred; the aſtronomical or ſolar are days of unequal length, being longer about the ſeaſon of the ſolſtices than at the equinoxes.

The *mean ſolar day* is a period not marked out by the return of any obſervable phenomena, but an artificial interval of time diveſted of the above irregularities. This is effected by ſuppoſing the year divided into as many days as it really conſiſts of, but each of theſe days of an equal length. One of theſe imaginary days is called a mean ſolar day.

The accumulated difference of time that ariſes from adopting one of theſe meaſures in preference to the other is called the equation of time. For a more full account of the nature of this equation, ſee that article.

Siderial day is a period much uſed by aſtronomers, and is that in which the earth makes one entire revolution on its axis. Here the ſtandard afforded by nature exceeds in exactneſs any imitation that can be produced by art. Hitherto at leaſt we have had no indication from aſtronomical obſervation of any irregularity in the earth's diurnal rotation; and as theory ſuggeſts none, we uſually make it the ſtandard to which we refer all other uniform motions.

Should there exiſt, however, any minute variation in the earth's revolution on its axis, it is by no means impoſſible that clocks may be brought to ſuch a degree of perfection as to detect it.

The ſolar day is longer than the ſiderial by about four minutes. This difference ariſes from the motion of the earth in its orbit.

For if on any day the centre of the ſun and a ſtar ſhould paſs the meridian at the ſame moment, the following day, when the ſtar paſſes and completes by its paſſage a ſiderial day, the ſun will appear to have moved to the eaſtward, and will not paſs the meridian till about four minutes after the ſtar. The mean difference between a ſolar and ſiderial day is $= 3' 56''$, but this is continually varying, its maximum being $= 4' 10''$, and its minimum $= 3' 35''$. Four times in a year the days are of their mean length. Twice a year they increaſe to a maximum, and twice a year are at their minimum: for example:

In this preſent year, 1808, the ſolar day is equal to the mean day on the 11th Feb.: it continues to decreaſe till the 25th March, when it becomes 20″ ſhorter than the mean day; from this period it begins to increaſe, and on the 14th May it equals the mean day, and continually increaſes till the 21ſt June. From the 21ſt June it decreaſes till the 14th September, the mean length taking place on the 27th July. From this time it increaſes till the 22d Dec., when its length is a maximum. From Dec. they continue to diminiſh till the following March, when nearly the ſame variations again take place. Two cauſes, independent of each other, contribute to produce this irregularity in the exceſs of the ſolar above the ſiderial day, and conſequently in the total length of the day. One of theſe is the unequal motion of the earth in its orbit; the other, the inclination of the earth's axis to the plane of its orbit.

About the period of the ſummer ſolſtice, the earth is in its aphelion, and moves ſlower than at any other ſeaſon of the year. The ſolar day therefore differs leſs from a ſiderial day; for if the earth was ſtationary, they would be equal. And

if

if the earth moved in a contrary direction, the ſidireal day would exceed the ſolar day.

On the contrary, in the month of January, the earth being in that part of its orbit neareſt the ſun, moves quicker, and the exceſs of the ſolar above the ſiderial day is greater.

To explain the effect of the ſecond cauſe, it muſt be obſerved that this exceſs of the ſolar or aſtronomical day is meaſured, by reducing the apparent motion of the ſun in the ecliptic to the equator, on which circle we always meaſure the angular motion of the earth round its axis.

If we imagine two great circles of the ſphere to paſs through the ſmall arc of the ecliptic, which the ſun deſcribes in one day, and through the poles; the arc of the equator which they intercept will be the daily motion of the ſun reduced to the equator, and the time required for this arc to paſs the meridian is the exceſs of the ſolar above the ſiderial day. Now at the equinoxes this ſmall arc of the equator will be leſs than the correſponding arc of the ecliptic in the ratio of the coſine of the obliquity of the ecliptic to radius; but at the ſolſtices it is greater in the ratio of the radius to the ſame obliquity. The ſolar day is therefore diminiſhed in the firſt caſe, and augmented in the ſecond. The method of calculating the preciſe effect of theſe inequalities will be given in the article EQUATION *of Time*.

To obtain a mean day independent of theſe cauſes, we may ſuppoſe a ſecond ſun moving uniformly along the ecliptic, and traverſing the greater axis of the ellipſe, at the ſame inſtant with the true ſun: this ſuppoſition will cauſe the inequality ariſing from the proper motion of the ſun to diſappear. The inequality ariſing from the obliquity of the ecliptic may be likewiſe removed by imagining a third ſun, paſſing the equinoxes at the ſame moment as the ſecond, and moving in the equator in ſuch a manner that the angular diſtances of theſe two ſuns from the point of the vernal equinox ſhall always be equal. The interval of time, which would elapſe between two ſucceſſive tranſits of this laſt imaginary ſun over the meridian, conſtitutes a mean ſolar day.

Mean time is meaſured by the number of theſe imaginary tranſits. True time by the tranſits of the real ſun.

The unequal length of the days and nights in different climates, or in the ſame climate at different ſeaſons, is another effect of the inclination of the earth's axis to the plane of its orbit.

If the ecliptic coincided with the equator, the circle bounding light and darkneſs would always divide the equator and all its parallels into two equal parts, and there would be equal day and night every where throughout the year. But by the inclination of the axis, the equator alone remains biſected as before, and all the other circles unequally divided except on the day of the equinox. After which, one pole with its adjacent circles will be gradually plunged into total obſcurity, and the oppoſite pole with its circles brought out into conſtant light.

At the ſolſtices the portion of total obſcurity, and conſtant illumination, will extend from the poles a number of degrees equal to the obliquity of the ecliptic.

The length of the day in any latitude, at any ſeaſon, may be found by the ſolution of a right angled ſpherical triangle, in which the diſtance of the ſun from the pole, and the altitude of the pole above the horizon, form the two known ſides, and a portion of the horizon the other. The angle required is the ſemidiurnal arc or hour angle, formed by the meridian and a great circle paſſing through the poles and the centre of the riſing or ſetting ſun.

This is ſhewn (*Plate* V. *Aſtron. fig.* 43.) In the right angled triangle P ⊙ O, the polar diſtance of the ſun P ⊙, and the latitude of the place, P O, are given. The angle required ⊙ P O, or more properly its complement Z P ⊙, is the ſemidiurnal arc, or the time elapſed from ſun-riſe to noon, or from noon to ſun-ſet.

Nations have differed much from each other as to the commencement, and ſtill more in the diviſion of the day. The Chaldæans, Syrians, Perſians, and Indians began the day at ſun-riſe, and divided both the day and night into four parts. This diviſion of the day into quarters was in uſe long before the invention of hours. The Chineſe, who begin their day at midnight and reckon to the midnight following, divide this interval into 12 hours, each equal to two of ours, and diſtinguiſhed by a name and particular figure. The Romans called the time between the riſing and ſetting ſun, the natural day, and the time in the whole four and twenty hours the civil day, and this definition has been adopted in modern Europe. They began and ended their civil day at midnight, and derived this practice from their ancient juriſprudence, and rites of religion, eſtabliſhed long before they had any idea of the diviſion into hours. According to Varro, the firſt ſun-dial ſeen at Rome was brought from Catana in Sicily, in the firſt Punic war, as part of the ſpoils of that city. It was erected unſkilfully in the forum, and though it probably was not adapted to the latitude of the place, yet it was the only meaſure of hours they had for near a century afterwards. Thus it appears that the Romans learnt the diviſion of the day into hours from a dial of Greek conſtruction. The Greeks divided the natural day into 12 hours, a practice, which according to Herodotus, they derived from the Babylonians. Theſe hours were of courſe unequal at different ſeaſons of the year, varying in the ſame proportion as the length of the natural day.

Such were the hours of Polybius in the time of the Roman republic, and of Plutarch and other Greek authors, under the emperors; and ſuch they continued at Conſtantinople, when the weſtern empire was no more. Palladius, "de re ruſtica," gives the huſbandman a calendar of hours, and teaches him to diſtinguiſh them in every month of the year, by the length of a ſhadow projected by a perpendicular pole. This ſhadow decreaſes from the firſt to the ſixth hour, when it is ſhorteſt; it then increaſes again. At the firſt hour in the morning and the eleventh in the afternoon he makes it always equal. Thus when Pliny directs that apples in autumn ſhould not be gathered, *Ante horam primam* (Nat. Hiſt. lib. xv. cap. xviii.) he means till they have had an hour's ſun upon them. The nocturnal hours were reckoned in the ſame manner as thoſe of the day. Midnight was the ſixth hour of the night. It appears from a paſſage in Varro, that an officer called accenſus, uſed, by order of the prætor, to proclaim the third hour, mid-day, and the ninth hour. Theſe diviſions of the natural day into four parts were called vigils, the firſt beginning at ſun riſe, the ſecond at the third hour, the third at mid-day, and the fourth at the ninth hour. The night was in the ſame manner divided into four vigils. And throughout the Turkiſh empire at this day, time is reckoned by certain portions of the natural day, reſembling the vigils of the ancient Jews and Romans. Public clocks not being in uſe, theſe diviſions of time are proclaimed from the minarets. Their principal diviſion of the natural day is into four parts, which are unequal at different ſeaſons, and in different parts of the empire.

There can be no doubt but that men of ſcience among the ancients were acquainted with equal hours. Pliny calls them equinoxial hours. Theſe were uſed in aſtronomical calculations, for computing the length of the day in different climates and ſeaſons. In Egypt likewiſe the day was divided into unequal hours. Ptolemy marks the time of the ſame phenomenon, by theſe as well as equa hours, to accommodate

his

his writings to the uſage of his country. The clock invented by Cteſibius (a celebrated mechanic of Alexandria, who lived 136 years before Chriſt) was ſo contrived as to lengthen or ſhorten the hours. About the thirteenth century, a more regular diviſion of the day into equal hours was introduced into Italy. The civil day was made to begin about the cloſe of evening twilight, and 24 equal hours are counted regularly on to the ſame time on the following evening. This mode is continued in many parts of Germany and Italy to this day. The clocks are uſually only numbered to, and ſtrike ſix, making four revolutions in one day. This method is very inconvenient, as noon and the various offices of civil life occur perpetually at a different hour, ſo that a perſon muſt conſult an almanac to know the hour of dinner. The accumulated error which the clocks are liable to, from this unſkilful mode of computation, is corrected when it amounts to a quarter of an hour. To enable the people to regulate their domeſtic concerns, a calendar is publiſhed, which announces, for inſtance, that from the 16th of Feb. to the 24th, it will be noon at a quarter paſt 18. That from the 1ſt of June to the 13th of July, it will be noon at 16. But the Italians are now gradually adopting the more improved method which has ſo long been practiſed in France, England, and the other enlightened countries of the north of Europe.

The only difference that at preſent ſubſiſts in England and France relative to the diviſion of the day is, that with us, we reckon by mean time. In France they uſe ſolar time. Our clocks ſometimes ſtrike twelve when the ſun is more than a quarter of an hour from the meridian. In France, the clocks ſtrike twelve at the moment of noon.

The French aſtronomers have lately propoſed, that the aſtronomical day ſhould commence with the civil day at midnight.

The names which have been appropriated to different days of the week in modern Europe, have been originally tranſmitted to us by the Romans: but the Northern nations have made ſome alteration, by ſubſtituting for the Roman divinities, ſuch of their own as moſt nearly reſembled them in their peculiar attributes. Thus the third day of the week, conſecrated by the Romans to Mars, was named from the Scandinavian deity Tyr. In the Daniſh and Swediſh language it is Tyrſdag, from whence our Tueſday. Tyr was an inferior deity, but preſided over battles: and Tacitus renders the name Tyr by that of Mars, and makes him inferior to Odin, whom he deſcribes under the name of Mercury.

From this Odin, or Wodin, we derive Wedneſday, anſwering to dies Mercurii. Thurſday is the day of the great god Thor, the moſt formidable of the Northern deities. The goddeſs Freya, from whom we derive our Friday, bears a ſtill greater reſemblance to Venus; and ſo ſtriking is the analogy, that ſome authors have conſidered it as more than probable that the mythology of the barbarous nations of the North had a common origin with that of the Greeks and Romans.

DAY, THOMAS, in *Biography*, an Engliſh writer of conſiderable merit, was born at London in 1748. His father dying while he was an infant, the care of his education devolved wholly upon his mother, a woman of ſtrong ſenſe, and a ſound and highly cultivated judgment, to whom our author was much indebted for that manly independence and benevolent ſpirit which he exhibited in every ſituation of life. He received the elementary parts of his education at the Charter-houſe, from whence he removed to Corpus-Chriſti college, Oxford. In 1765, he entered at the Middle Temple, and ſtudied the law ſufficiently to be called to the bar. After this he ſpent ſome years in foreign travel, rather with a view of ſtudying men and manners, than of examining the countries in a topographical view. The fruit of his reſearches into the condition of his fellow creatures, excited in him ſentiments of wretchedneſs bordering upon melancholy: but the ſtrength of his mind, and the excellent impreſſions left by a good education, enabled him to overcome the languor into which he was falling, and he became the determined foe of tyranny in every ſhape, and the zealous advocate and patron of the rights of men. In 1778, he married Miſs Milnes of Wakefield, a lady poſſeſſed of a fine underſtanding, and, at the ſame time, capable of conforming to the peculiarities of Mr. Day. He reſided, firſt at Staple-ford Abbots in Eſſex, and afterwards he took a farm near Chertſey in Surrey, in which he employed many of the neighbouring poor in experimental proceſſes. About the year 1780, he became the public opponent to the American war, the principal of which he had always abhorred; and he took a zealous part with thoſe who were contending for parliamentary reform, which he conſidered as the foundation of thoſe other political reforms which were thought by a very reſpectable body of the people to be eſſential to the exiſtence of the country. About this period, he publiſhed many political pieces in proſe and in verſe, all of which were anonymous, but they pointed out the author as an ardent friend to civil liberty, and as abhorrent to the principles of ſlavery in every quarter of the globe. But Mr. Day's name will be long dear to the young, and to thoſe who have the charge of education devolved upon them, by his "Hiſtory of Sandford and Merton," in three volumes; and his "Hiſtory of Little Jack," in one ſmall volume. The former of theſe works powerfully inculcates all the manly virtues of courage, activity, temperance, independence, and generoſity, and contains many uſeful inſtructions in the principles of ſcience. The moral of the ſtory of Little Jack, which is entertaining, and diſplays the good effects of activity, induſtry, ſobriety, and honeſty, is, that it is of very little conſequence how a man comes into the world, provided he behaves well, and diſcharges his duty when he is in it.

In the midſt of his endeavours to do good, and to promote the intereſts of his fellow creatures, Mr. Day was cut off by an unfortunate accident. As he was riding from his own to his mother's houſe, on Sept. 28, 1789, he was killed by a fall from his horſe, being only in the 42d year of his age.

In private life Mr. Day was a faithful and tender huſband, an affectionate ſon, and a generous and ſympathizing friend. He was remarkably plain in his dreſs: in the choice of his food, he was far from being nice and delicate, not, however, from the want of a very diſcriminating taſte, but becauſe he had obſerved that a faſtidiouſneſs of appetite is often productive of evil conſequences. His mode of travelling was as ſimple and unexpenſive as poſſible; the reaſon he aſſigned for which was, that the leſs he ſpent upon himſelf, the more he could afford for the wants of his fellow creatures. In conſequence of the wide range of his charity, and the unoſtentatious manner in which it was beſtowed, many of his beneficent actions are now totally unknown. Few returned from him empty-handed, for he ſaid that "he loved to give." But the private character of Mr. Day ſhall be given in the words of his widow: "The undeviating firmneſs, independence, and diſintereſtedneſs of Mr. Day's character, in an age of ſuch venality, corruption, and effeminacy as the preſent, might ſurely be conſidered as a ſingular phenomenon. As I, of all human beings, was the moſt intimately acquainted with the extraordinary and invariable ſimplicity of his life and manners, I do not ſcruple

to ſay that this, united to his patriotic ſpirit (with the opinion I entertained of his eloquence and ability), continually reminded me of thoſe great and virtuous characters of ancient times, who, deſpiſing the common objects of ambition, cultivated their farms, and yet were ever ready, when occaſion called, to exert themſelves in defence of the rights and liberties of their country. My huſband's conduct was in a great meaſure conformable to that ſentiment of Rouſſeau, "while there is one of our fellow creatures who wants the neceſſaries of life, what virtuous man will riot in its ſuperfluities." Dr. Kippis, in the Biographia Britannica, has given an intereſting analyſis of the works of Mr. Day, to which the reader muſt be referred for information on this head. "If Mr. Day's life had been continued," ſays his excellent biographer, "he would undoubtedly have exerted his talents in farther productions for the benefit of mankind. But though his premature death muſt ever be regretted, his ſurviving friends will have the conſolation of reflecting that he lived long enough to exhibit a pattern of diſintereſted virtue and ardent philanthropy, which, it is hoped, cannot be uſeleſs to the world."

Day, John, the firſt printer of muſic in England upon five lines. Before the reformation, the canto fermo in the miſſals, breviaries, &c. of the Roman church, had been printed on four lines in Gregorian notes, very ſoon after the invention of the preſs; but no prickt diſcant, or figurative muſic, was publiſhed till the firſt year of queen Elizabeth, when a choral work appeared, "**Certaine notes ſet forth in four and three partes, to be ſong at the Morning Communion and Evening Praier very neceſſarie for the Church of Chriſte to be frequented and uſed: and unto them be added divers Godly Praiers and Pſalmes, in the like forme, to the honour and praiſe of God. Imprinted at London, over Aldersgate, beneath St. Martins, by John Day.** 1560. The authors of theſe compoſitions were Tallis, Cawſton, Johnſon, Oakland, Shepherd, and Taverner.

Day, in *Law*, is frequently uſed for the day of appearance in court, either originally, or upon aſſignation. There is a day of appearance in court by the *writ* and by the *roll*; by *writ*, when the ſheriff returns the writ; by *roll*, when he hath a day by the roll, and the ſheriff returns not the writ, there the defendant, to ſave his freehold, and prevent loſs of iſſues, impriſonment, &c. may appear by the day he hath by the roll. (Co. Litt. 135.) In real actions there are *dies communes*, common days; and in all ſummonſes there muſt be 15 days after the ſummons, before the appearance; and before the ſtatute of "Articuli ſuper Chartas," in all ſummonſes and attachments in plea of land, there ſhould be contained 15 days. (Co. Litt. 134.) As to offences in B. R., if the offence be committed in another county than where the court ſits, and the indictment be removed by *certiorari*, there muſt be 15 days between every proceſs and the return thereof; but if it be committed in the ſame county where the bench ſits, they may ſit *de die in diem*; but this they will very rarely do. (Ibid.) There is a day called *dies ſpecialis*, as in an aſſiſe in the king's bench or common pleas, the attachment need not be 15 days before the appearance, otherwiſe it is before juſtices aſſigned; but generally in aſſiſes the judges may give a ſpecial day at their pleaſure, and are not bound to the common days; and theſe days they may give as well out of term as within. There is alſo a day of grace, *dies gratiæ*; and generally this is granted by the court at the prayer of the demandant or plaintiff, in whoſe delay it is; but it is never granted where the king is party, by *aid prier* of the tenant or defendant; nor where any lord of parliament, or peer of the realm, is tenant or defendant. And ſometimes the day that is *quarto die poſt*, is called *dies gratiæ*, for the very day of return is the day in law, and to that day the judgment hath relation, but no default ſhall be recorded till the fourth day be paſt; unleſs it be in a writ of right, where the law alloweth no day but the day of the return. Co. Litt. 135.

There are ſeveral *return days* in the terms; and if either of them happen upon a Sunday, the day following is taken inſtead of it: for Sunday is *dies non juridicus*: and ſo is Aſcenſion day in Eaſter term, St. John the Baptiſt in Trinity term, All Saints and All Souls in Michaelmas term, and the Purification of the Virgin Mary in Hilary term. 2 Inſt. 264.

If a fact be done in the night, you muſt ſay in law proceedings, *nocte ejuſdem diei*.

To be diſmiſſed *without day* is to be finally diſmiſſed the court; and when the juſtices before whom cauſes were depending, do not come on the day to which they were continued, whether ſuch abſence be occaſioned by death or otherwiſe, they are ſaid to be *put without day*; and may be received, or re-conſidered by re-ſummons, re-attachment, &c. (See ſtat. 1 Ed. VI. c. 7.) Alſo, by the common-law, all proceedings upon any indictment, &c. whereon no judgment had been given, were determined by the demiſe of the king, and nothing remained but the indictment, original writ, &c., which were *put without day*, till re-continued by re-attachment to bring in the defendants to plead *de novo*; though this is remedied by ſtat. 4 and 5 W. III. c. 18. 1 Ann. c. 8.; by which ſuch proceſs, &c are to continue in the ſame force after the king's demiſe, as they would have done if he had lived.

In action of treſpaſs, if the day laid in the declaration be either *before* or *after* the actual day on which the treſpaſs is committed, it is not material, if a treſpaſs be proved. (Co. Litt. 283, *a*.) But the day laid muſt be before the firſt day of that term of which the declaration is entitled; or if the treſpaſs be committed within the term, there muſt be a ſpecial memorandum of ſome particular day (if by bill), or of ſome general return-day (if in C. P. or B. R. by original writ), *ſubſequent* to the day wherein the treſpaſs was committed; and ſo as to other actions where the cauſe of action ariſes *within* the term. Jacob's Law-Dictionary by Tomlins.

Day-*Coal*, in *Natural Hiſtory*, a name given by the miners of England, and the common people who live in coal countries, to that ſeam or ſtratum of the coal which lies uppermoſt in the earth. The ſame vein or ſtratum of coal uſually runs a great way through the country, and dips and riſes in the earth in different places; ſo that this upper ſtratum, or day-coal, is, in the various parts of the ſame ſtratum, ſometimes near the ſurface, and ſometimes at many fathoms deep. The ſubterranean fires found in ſome of our coal countries principally feed on this coal, and are nearer, or farther from the ſurface, as it riſes or ſinks. Phil. Tranſ. N° 130.

Day-*Labourer*, in *Agriculture*, a perſon who works by the day.

Day-*Light*, in *Law*. In reſpect to day-light, before ſun-riſing, and after ſun-ſetting, is accounted part of the day by common law; as to robberies committed in the day-time, when the hundred is liable. 7 Rep. 6.

The law regularly rejects all fractions and diviſions of a day, for the uncertainty. 5 Rep. 1. 1 Inſt. 135.

Day-*Lily*, in *Botany*. See Hemerocallis.

Day-*Rule*, in *Law*. See Day-*Writ*, *infra*.

Day-*Work*, in *Rural Economy*, ſuch work as is performed by the day.

Day's-

DAY's-*Work*, in *Sea Language*, denotes the reckoning or account of the ſhip's courſe, during twenty-four hours, or between noon and noon, according to the rules of trigonometry. See DEAD-*reckoning*.

DAY-*Writ*, or DAY-*rule*, in *Law*, a rule or order of court, permitting a priſoner in cuſtody in the king's bench priſon, &c. to go without the bounds of his priſon for *one day*. By rule of the court of king's bench, Eaſter, 30 Geo. III. a priſoner ſhall not have day-rules, above three days in each term, and he is to return to priſon before nine in the evening. The king may grant "writ of warrantia diei" to any perſon, who ſhall ſave his default for *one day*, be it in plea of land or other action, and be the cauſe true or not; and this by his prerogative. (Br. Prerogative, pl. 142, cites F. N. B. 7.) It is againſt law to grant liberty to "priſoners in execution," by other writs than day-writs or rules. (Chan. Rep. 67.) No priſoner, committed by B. R., ought to have the benefit of the day-rule of going abroad in term-time; for their impriſonment is their puniſhment for their contempt or miſbehaviour. (2 Show. 88. pl. 80.)

DAYS *in Bank*, are days ſet down by ſtatute, or order of the court, when writs ſhall be returned, or when the party ſhall appear on the writ ſerved. See ſtat. 51 H. III. ſtat. 2 and 3. 32 Hen. VIII. c. 21. 16 Car. I. c. 6. 24 Geo. II. c. 48. And by the ſtatute "De anno biſſextili," (21 H. III.) the day increaſing in the leap-year, and the day next going before, are to be accounted but one day.

It is commonly ſaid, that the day of Niſi Prius, and the day in the Bank, are one day; but this is to be underſtood as to pleading, and not to other purpoſes. (1 Inſt. 135.) But after iſſue found for the plaintiff at the Niſi Prius, if a day be given in Bank, and the defendant makes default, judgment ſhall be given againſt him. (2. Danv. Ab. 477.)

DAYS *of Grace*. See DAY.

DAYS *of Grace*, in *Commerce*, are a number of days allowed by cuſtom for the payment of a bill of exchange after the ſame becomes due; *i. e.* after the time it was accepted for is expired.

In England, three *days of grace* are allowed: ſo that a bill accepted, in order to be paid, *e. gr.* ten days after ſight, is not to be paid till thirteen days. Throughout France, they allow ten *days of grace;* as many at Dantzic; eight at Naples; ſix at Venice, Amſterdam, Rotterdam, and Antwerp; four at Frankfort; five at Leipſic; twelve at Hamburgh; eight at Copenhagen; three at Berlin; ſix in Portugal; fourteen in Spain; thirty in Genoa, &c. Note, Sundays and holidays are included in the number of *days of grace*.

DAYS-*Man* is uſed, in ſome parts of England, for an arbitrator or judge: and it has been obſerved, that the word *day* ſignifies judgment.

DAYS *of Prefixion*. See REMEMBRANCER.

DAYS, *Fiſh*. See ABSTINENCE.

DAYS, *Dog*, *Dies caniculares*. See CANICULAR.

DAYS, *Critical*, *Dies critici*. See CRITICAL *days*.

DAYS, *Intercalary*, *additional*. See INTERCALARY *days*.

DAYA, in *Geography*, a town ſituated on the weſt coaſt of the iſland of Sumatra, on a river of the ſame name; 30 miles S. of Acheen.

DAYMAR, a town of Arabia, in the country of Omar: 220 miles S. of Maſcat.

DAYTON, a ſmall ſettlement of America, in the ſtate of Ohio, and county of Montgomery.

DEA, in *Geography*, a town of Perſia, in the province of Segeſtan, 60 miles S. W. of Kin.

DEA *Vocontiorum*, *Die*, in *Ancient Geography*, a town of Gallia Viennenſis, which belonged to the Vocontians.

DEABAGEN, in *Geography*, a town of Aſia, in the country of Candahar; 30 miles N. W. of Candahar.

DEACON, *Diaconus*, in *Eccleſiaſtical Hiſtory*, a perſon who belonged to the inferior order of miniſters in the Chriſtian church.

The word is formed from the Latin *diaconus*, of the Greek διακονος, *miniſter*, *ſervant*.

Deacons were firſt inſtituted, ſeven in number, by the apoſtles, Acts, chap. vi. which number was retained a long time in ſeveral churches. Grotius apprehends that the order of deacons in the Chriſtian church correſponded to that of eleemoſynaries in the Jewiſh ſynagogue. Their office was, to ſerve in the agapæ, and to diſtribute the bread and wine to the communicants, and diſpenſe the alms.

Their original inſtitution was to *ſerve tables*, which office included the care of the poor, and an attendance at the Lord's table. As for the care of the poor, Origen tells us (Comment. in Matt. tom. 16, p. 443, vol. 1.) that the "deacons diſpenſed to them the money of the church," being employed under the biſhop to inſpect and relieve all the indigent within their dioceſe; and as for their attendance at the Lord's table, their office, with reſpect to that, conſiſted in preparing the bread and wine, in cleanſing the ſacramental cup, and other ſuch neceſſary things, whence they are called by Ignatius (Epiſt. ad Tralles. p. 48.) "deacons of meats and cups," aſſiſting alſo, in ſome places at leaſt, the biſhops or preſbyters in the celebration of the euchariſt, "delivering the elements to the communicants." (Juſt. Mart. Apolog. 2. p. 97.) Tertullian informs us, (De Bapt. p. 602.) that the deacons preached, and, "in the abſence of the biſhops and preſbyters, baptized." In a word they were, according to the ſignification of their name, and as Ignatius calls them (ubi ſupra) "the ſervants of the churches," ſet apart on purpoſe to ſerve God, and attend on their buſineſs, being conſtituted, as Euſebius terms it, (lib. ii. cap. 1.) "for the ſervice of the public." King's Conſt., &c. of the primitive Church, p. 80.

The office of deacon was, at its firſt inſtitution, a truſt in things merely temporal, or what Jerom called "the ſervice of tables and widows." They were no other than what, in modern language, we ſhould call the church's almoners. Nor is it any objection, as Dr. Campbell ſuggeſts (Lect. on Eccleſiaſtical Hiſtory, vol. i. p. 245.) that we find both Stephen and Philip, who were among the ſeven deacons that were firſt preſented by the people to the apoſtles, exerciſing ſpiritual functions, ſuch as preaching and baptizing. This power they certainly did not derive from the ſuperintendency of the people's charities, to which alone they were choſen, with which they were entruſted, and which the apoſtles, in the very inſtitution of the office, expreſsly diſtinguiſh from the miniſtry of the word. (Acts, vi. 1—4.) Here the διακονια τραπεζων, and the διακονια λογου, are manifeſtly contraſted to each other. Stephen and Philip, on the contrary, derived their ſpiritual functions, either from that title, with which, according to Tertullian and the deacon Hilarius, every qualified perſon, in that ſtate of the church, was inveſted for promoting the common cauſe, or from the ſupernatural gifts they had received for the advancement of the faith, before their election to the deaconry, or, as ſome have thought moſt probable, from their being called of God to the office of evangeliſts. Philip is in another place, but at a later period, expreſsly called an evangeliſt. (Acts, xxi. 8.) It is worthy of notice, that his office of deacon is there alſo named, that we may not confound them, or aſcribe to the one what belonged to the other.

other. Soon after the apoſtolic age, (or perhaps ſooner,) though we have no direct information concerning it, the deacons were admitted to aſſiſt in the inferior parts of the ſacred ſervice. At preſent, indeed, in almoſt all the churches, where the three orders of biſhop, preſbyter, and deacon are found, the laſt-mentioned has no ſort of charge in that particular, which was at firſt his whole charge, and which alone gave occaſion for the inſtitution of the office; inſomuch that we cannot ſay the modern deacon is in any reſpect the ſame with the apoſtolic deacon, unleſs it be in the name. Properly the original charge of the inſtitution, of which we are informed in Acts vi. 1, is aboliſhed, though the name be retained, and applied to an office totally diſtinct. At preſent the overſight of the poor belongs, in England, to the church-wardens, who are annually elected in each pariſh by the veſtry. The deacons have no concern in it. In other churches, other methods are adopted.

By the ancient canons, marriage was not incompatible with the ſtate and miniſtry of a deacon; but it is now a long time that the Romiſh church has prohibited their marrying; and the pope only grants them diſpenſations for very important cauſes; and, after this diſpenſation, they loſe the rank and functions of their order, and return to a lay ſtate.

At Rome, under pope Sylveſter, they had only one deacon; then ſeven were appointed; then fourteen; and, at laſt, eighteen; who were called cardinal deacons, to diſtinguiſh them from thoſe of other churches.

Their office was, to take care of the temporalities of the church, to look to the rents and charities, and provide for the neceſſities of the eccleſiaſtics, and even of the pope. The collecting of the rents, alms, &c. belonged to the ſubdeacons; the deacons were the depoſitaries and diſtributors. Having thus the management of the revenues of the church in their hands, their authority grew apace, as the riches of the church increaſed. Thoſe of Rome, as being miniſters of the firſt church, preceded all others, and even at length took place of the prieſts themſelves. Doubtleſs, it was the avarice of the prieſts that made them give place to the deacons, who had the diſpoſal of the money.

The deacons rehearſed certain prayers at the holy office, which were thence denominated *diaconical*.

They took care that the people at church behaved themſelves with due modeſty and reſpect. They were not allowed to teach publicly; at leaſt not in the preſence of a biſhop or prieſt. They only inſtructed the catechumens, and prepared them for baptiſm. The doors of the church were likewiſe in their cuſtody; though, in after-times, that charge was committed to the ſubdeacons.

Theſe ſubdeacons are mentioned both by Cyprian, (Epiſt. 24.) and Cornelius, (apud Euſeb. l. vi. c. 43.) As the office of the preſbyters was to aſſiſt and help the biſhops, ſo theirs was to aſſiſt and help the deacons. And as the preſbyters, ſays lord King, (Conſt. &c. of the Primitive Church, p. 81.) were of the ſame order with the biſhop, (ſee BISHOP) ſo probably the ſubdeacons were of the ſame order with the deacons, which we may infer from the origin and riſe of theſe ſubdeacons, which might be this, that in no church whatſoever was it uſual to have more than ſeven deacons, becauſe that was the original number inſtituted by the apoſtles; and, therefore, when any church became ſo great and numerous, that this limited number of deacons was not ſufficient to diſcharge their neceſſary miniſtrations, that they might not ſeem to deviate from the apoſtolical example, they added aſſiſtants to the deacons, whom they called ſubdeacons or under-deacons, who were employed by the head or chief deacons to perform thoſe ſervices in their room, to which, by their office, they were obliged.

The office of a deacon, in the church of England, according to the form of ordination, is to baptize, preach, and aſſiſt in the adminiſtration of the Lord's ſupper; and, in ſhort, to perform all the other offices in the liturgy, which a prieſt can do, except that of conſecrating the elements of the Lord's ſupper, and pronouncing the abſolution. No perſon can be ordained a deacon under the age of twenty-three years, unleſs by a faculty or diſpenſation obtained from the archbiſhop of Canterbury: and in order to this, he muſt be provided with a title to a cure, or be a fellow or chaplain in ſome college in Cambridge or Oxford, or a maſter of arts of five years ſtanding, living at his own charge in either of the univerſities, or be admitted by the biſhop, who ordains him to ſome benefice or curacy then void. Otherwiſe the ordaining biſhop ſhall maintain him, till he is preferred to ſome eccleſiaſtical living. And by ſtat. 13 and 14 Car. II. c. 4. no perſon is capable of being admitted to any benefice or eccleſiaſtical promotion, till he be ordained a prieſt; nor is a deacon capable of a donative, but is only allowed to uſe his orders as a chaplain to ſome family, a curate to ſome prieſt, or a lecturer without a title.

DEACONESS, *Diaconiſſa*, an office probably of apoſtolic inſtitution, though we have no information concerning the occaſion and manner of it, in uſe in the primitive church, from the times of the apoſtles, though now laid aſide. St. Paul makes mention of it in his Epiſtle to the Romans, (Rom. xvi. 1.): and the younger Pliny, in a letter to Trajan, tells that prince, that he had ordered two deaconeſſes, whom he calls miniſtræ, to be tortured.

Deaconeſs was a title given to certain devout elderly women, commonly widows, who conſecrated themſelves to the ſervice of the church, and rendered thoſe offices to the women, which men could not decently do: as in baptiſm, for inſtance, which was conferred, by immerſion, on women as well as men.

They were likewiſe to look to the doors on the ſide the women were on, who were ſeparated from the men, according to the cuſtom of thoſe times. They had the care and inſpection of the poor, ſick, &c. And in times of perſecution, when a deacon could not be ſent to the women, to exhort and fortify them, a deaconeſs was ſent. See Balſamon on the eleventh canon of the council of Laodicea; and the Apoſtolical Conſtitutions, lib. ii. cap. 57. To ſay nothing of the epiſtle of Ignatius to the people of Antioch; where what is ſaid of deaconeſſes is ſuppoſed to be an interpolation.

The council of Nice ranks deaconeſſes among the clergy, though ſome hold, that their ordination was not ſacramental, but a mere eccleſiaſtical ceremony. However, it gave them a pre-eminence above the reſt of their ſex; for which reaſon the council of Laodicea forbad the ordaining of any more for the future. The office of deaconeſſes expired in the Weſtern church about the twelfth century, and in the Eaſtern about the thirteenth.

Atto of Vercell, in his eighth letter, gives the reaſon of their being aboliſhed: he obſerves, that in the firſt ages the miniſtry of women was neceſſary, in order to the more eaſy inſtructing of other women, and recovering them from paganiſm; and that they likewiſe ſerved for the more decent adminiſtration of baptiſm to the ſame: but that it was not then neceſſary, becauſe none but children were baptized; and it might now be added, becauſe baptiſm is only conferred by ſprinkling.

The number of deaconeſſes does not ſeem to have been

fixed: the emperor Heraclius, in his letter to Sergius, patriarch of Conſtantinople, orders, that in the great church of Conſtantinople there be forty deaconeſſes; whereas there were only ſix in that of the Mother of God, in the quarter of the Blachernæ.

DEACONRY, DIACONATE, the order or miniſtry of a deacon or deaconeſs. See DEACON, and DEACONESS.

DEACONRY, *Diaconia*, is alſo a name ſtill reſerved to the chapels and oratories in Rome, under the direction of the ſeveral deacons, in their reſpective regions or quarters.

To the deaconries were annexed a ſort of hoſpitals, or board, for the diſtribution of alms, governed by the regionary deacons, called cardinal deacons, of whom there were ſeven, anſwering to the ſeven regions, their chief being called the arch-deacon.

The hoſpital adjoining to the church of the deaconry, had an adminiſtrator for the temporal concerns, called the father of the deaconry, who was ſometimes a prieſt, and ſometimes a layman.

There were fourteen of theſe deaconries, or hoſpitals at Rome, which was reſerved to the cardinals. Du Cange gives us their names: as the deaconry of St. Maria in the Broad-way, the deaconry of St. Euſtachio near the Pantheon, &c.

DEAD, in *Geography*, a river of South Wales, which runs into the Nevern near Newport, in the county of Pembroke.

DEAD-BEAT *Eſcapement*, in *Horology*, conſiſts of a ſwing-wheel and pallets, ſo peculiarly conſtructed, that the hand inſerted on the arbor of the ſwing-wheel, called the ſeconds hand, remains motionleſs, or, as it were, dead, during the remainder of the pendulum's vibration, after the eſcape has taken place. It had been obſerved, that thoſe pallets which check the natural vibrations of the pendulum, and produce a backward motion of the ſeconds' hand at every vibration, called a recoil, occaſion a clock to gain time when any addition is made to the maintaining power, and the contrary; or, which is the ſame thing, that a clock with ſuch pallets will loſe time by becoming dirty. The celebrated Graham, therefore, contrived that conſtruction of the pallets and ſwing-wheel, which conſtitute the dead-beat eſcapement, with a view of obviating this defect in clock-work, which indeed it does in a great meaſure, though a ſmaller oppoſite defect is thereby produced, *i. e.* with the common dead-beat eſcapement, an addition to the maintaining power produces a retardation in the rate, and conſequently a certain quantum of acceleration is the conſequence of foulneſs in the works. We might in this place have deſcribed in detail the particulars of the dead-beat eſcapement, but that we have already referred to the article ESCAPEMENT for them, where the reader will find a deſcription of the different eſcapements; and where, from the contraſt given of the different conſtructions of the various eſcapements, he will the better comprehend their relative merits. In the mean time he may turn to the paragraph *callipering*, in the article CLOCK-*making*, and conſult *fig.* 3. of *Plate* X. of *Horology*, in the latter of which he will find a geometrical delineation of the dead-beat eſcapement for a half ſeconds pendulum, and in the former meet with a correſponding deſcription.

DEAD-*Bell*, in *Mythology*, an omen credited among the Scottiſh peaſantry, which is ſaid to be a tinkling bell in the ears, regarded by the country people as the ſecret inteiligence of the deceaſe of ſome friend.

DEAD-CHEST *Iſland*, in *Geography*, one of the ſmaller Virgin iſles, ſituated near the eaſt end of Peter's iſland, and weſt of that of Cooper's.

DEAD *Lights*, in a *Ship*, are wooden ports made to faſten in the cabin windows, to prevent the waves from breaking into the ſhip in a high ſea.

DEAD-MAN's *Bay*, in *Geography*, a bay ſituated on the eaſt ſide of Newfoundland iſland, ſouth of St. John's harbour, and N. W. of cape Spear.

DEAD-MAN's *Head*, or *Point*, a cape of England on the coaſt of Cornwall, in the Engliſh channel. N. lat. 50° 13'. W. long. 4° 48'.

DEAD-MAN's *Iſland*, one of the Magdalen iſlands. N. lat. 47° 22'. W. long. 61° 30'.

DEAD-MAN's *Eyes*, or DEAD *eyes*, in *Ship-Rigging*, are round, flat, wooden blocks, with three holes, inſtead of ſheaves, through which the laniards reeve, when ſetting up the ſhrouds or ſtays. The power gained by dead-eyes is as the number of parts of the laniards reeved through them; but, if the laniards be not well-greaſed, the power will be greatly loſt by friction, ſo that they are never applied as purchaſes, but merely for the better keeping the quantity gained of any ſhroud or ſtay, when ſet up, and are much ſtronger than blocks with ſheaves, when ſtrain lies on a ſingle pin.

DEAD-*Nettle*, in *Botany*. See LAMIUM.

DEAD-*Nettle, yellow*. See GALEOPSIS.

DEAD-*Pledge*, in *Law*. See MORTGAGE.

DEAD-*Reckoning*, in *Sea Language*, is that eſtimation, judgment, or conjecture, which the ſeamen make of the place where a ſhip is, by keeping an account of her way by the log, by knowing the courſe they have ſteered by the compaſs, and by rectifying all, with allowance for drift, lee-way, &c. according to the ſhip's trim; ſo that this reckoning is without any obſervation of the ſun, moon, or ſtars, and is to be rectified as often as any good obſervation can be had. See LOG.

DEAD-*Riſing*, a term in a ſhip for that part of her bottom, through her whole length, where the floor timber is terminated upon the lower futtock.

DEAD-*Ropes*, in a ſhip, are ſuch as are not running, *i. e.* which do not run in any block.

DEAD-*Sea*, in *Geography*. See ASPHALTITE *Lake*.

DEAD-*Sea, Chemical Analyſis of its Waters*.—The waters of the Dead ſea, or lake Aſphaltites, have been from time immemorial remarkable for their intenſe ſaltneſs, which is ſo great that no fiſh, inſect, or any living animal is found in them, and the banks are perfectly barren. The ſame intenſe ſaltneſs alſo gives ſo great a ſpecific gravity, that the human body cannot ſink in it; diving in it is impracticable; and Pococke relates, that he could lie on its ſurface motionleſs in any attitude.

A ſpecimen of this water was analyſed by Meſſ. Macquer and Lavoiſier, the account of which was publiſhed in the Memoirs de l'Academie des Sciences for 1778; and a more careful, and therefore more accurate, analyſis has lately been made by Dr. Marcet on a ſmall portion collected by Mr. Gordon of Clunie, in his travels into Paleſtine, and tranſmitted by him to Sir J. Banks. From Dr. Marcet's analyſis (publiſhed in the Philoſophical Tranſactions for 1807, part 2.) we may give the following particulars.

The water is perfectly tranſparent and colourleſs, and does not depoſite any cryſtals on ſtanding in cloſe veſſels. Its taſte is peculiarly bitter, ſaline, and pungent. Its ſpecific gravity is as high as 1.211, which is greater that that of any other known natural water of any conſiderable extent. It is however not ſaturated with ſalt, for it will diſſolve more when added to it: it is neither acid, nor alkaline, but perfectly neutralized. By chemical teſts, the preſence of lime, magneſia, muriatic, and ſulphuric acid, are readily detected.

We ſhall not here detail the particular proceſſes by which Dr.

Dr. Marcet obtained a very ſatisfactory analyſis of the contents of this water, but the reſults are the following:

A hundred grains of the water contain of

	Grains.
Muriat of lime	3.920
Muriat of magneſia	10.246
Muriat of ſoda	10.360
Sulphat of lime	0.054
	24.580

All the ſalts here mentioned are eſtimated as in a ſtate of thorough deſiccation, or that in which no water whatever is preſent, except what appears eſſential to the conſtitution of the acid at a red heat. This degree of dryneſs, however, can only be inferred with regard to the muriats by eſtimation from collateral experiments; for when thoſe are dried at 180° (above which point they loſe alſo part of their acid), they contain about $1\frac{1}{2}$ times their weight of water. The numbers here given differ ſomewhat from thoſe found by another mode of analyſis, but this difference is ſo ſmall as only to confirm and not invalidate the general accuracy of the experiments.

On the whole, therefore, it appears that the water of the Dead ſea contains about a fourth of its weight of ſalts, when in perfect deſiccation; and of theſe ſalts about $\frac{5}{7}$ths are common ſalt, and the remainder almoſt entirely a mixture of the muriats of lime and magneſia; the latter in by much the largeſt proportion.

We may add, that a ſmall quantity of the water of the river Jordan (which is the only ſtream of any conſiderable ſize that terminates in the Dead ſea) was alſo analyſed by Dr. Marcet. This is a very pure ſoft taſteleſs water, remarkably different in ſenſible properties from that of the Dead ſea; but on evaporation a minute quantity of ſalts were obtained, which were found to be a mixture of the ſame as thoſe of the lake, but in too ſmall proportion for analyſis.

Dead-*Tops*, in *Rural Economy*, a diſeaſe incident to young trees; and cured by cutting off the dead parts cloſe to the next good twig or ſhoot, and claying them over as in grafting.

Dead *Water*, is the eddy water juſt behind the ſtern of a ſhip. It is ſo called, becauſe it does not paſs away ſo ſwiftly, as the water running by her ſides doth.

If a ſhip have a great eddy following her ſtern, they ſay, ſhe makes much dead-water.

Dead-*Wood*, in *Naval Architecture*, a name given by ſhipwrights to certain blocks of timber laid upon the keel, particularly at the extremities afore and abaft, where theſe pieces are placed upon one another to a conſiderable height, becauſe the ſhip is there ſo narrow, as not to admit of the two half-timbers, which are therefore ſcored into the dead-wood, where the angle of the floor-timbers greatly diminiſhes as approaching the ſtern and ſtern-poſt. The dead-wood afore and abaft is equal in depth to two thirds the depth of the keel, and as broad as it can be, without exceeding the breadth of the keel.

Dead-*Work*, denotes all that part of a ſhip, which is above water when ſhe is laden.

DEADLY Carrot, in *Botany*. See Thapsia.

Deadly *Feud*, in our *Law Books*, a profeſſion of irreconcileable enmity till a perſon is revenged by the death of his enemy.

The word feud is derived from the German fehd, which, as Hottoman obſerves, ſignifies, modo bellum, modo capitales inimicitias. See Feud.

Such enmity and revenge were allowed by our ancient laws in the time of the Saxons; *viz.* if any man was killed, and a pecuniary ſatisfaction were not made to the kindred, it was lawful for them to take up arms, and revenge themſelves on the murderer; which was called deadly feud. And this, probably, was the original of an appeal.

Deadly *Nightſhade*. See Atropa.

DEADS, in *Mining*, is uſed to expreſs that part of the ſhelf or faſt ground which contains no ore; but which encloſes the vein or bed of the ore, like a wall on every ſide. The drifts which they ſink for the tin ore in Cornwall, are generally about three feet over, and about ſeven feet high; ſo that a man may conveniently ſtand upright at work, and manage his tools. In caſe the vein itſelf is not broad enough to allow this, as in many places it is not half a foot over, then they pick down the ſtrata that encloſe it, ſo as to make an opening of the ſame breadth. This work they call breaking up the deads. Phil. Tranſ. N° 69.

This word is alſo uſed for ſuch parcels of common looſe mould or earth, lying above the ſhelf, as uſually contain the ſhoad, which they find when they are training a load.

In the Mendip lead-mines, when a vein of ore breaks off abruptly in an earth, they call it a deading-bed; and earth without ore, they call dead-earth.

DEAF, in *Agriculture*, a term uſed to ſignify blaſted or barren, as applied to grain, nuts, &c.; thus we have deaf ears, deaf nuts, &c. ſignifying ſuch as are deſtitute of grain, kernels, &c.

DEAFFORESTED, in our *Law Books*, the being diſcharged from being foreſt: or freed and exempted from foreſt-laws. See Forest.

"Johannes Dei gratia, &c. archiepiſcopis, epiſcopis, &c. ſciatis nos omnino *deafforeſtaſſe* foreſtam de Brewood de omnibus, quæ ad foreſtam et foreſtarios pertinent. Quare volumus et firmiter præcipimus, quod prædicta foreſta, et homines in illa manentes, et hæredes eorum, ſint *deafforeſtati* in perpetuum."

DEAFNESS, in *Medicine*, imperfection or abolition of the faculty of hearing.

The cauſes of the loſs or imperfection of hearing are numerous, as will be readily conceived by any one, who conſiders the complex ſtructure of the ear: and the difficulty of diſtinguiſhing the modifications of deafneſs, as produced by theſe different cauſes, and conſequently of curing the diſeaſe, will be not leſs obvious, if the obſtacles, which nature has thrown in the way of ſuch an inquiry, be alſo taken into conſideration. The eſſential parts of the organization of the ear are ſituated within a bony caſe, beyond the reach of examination, and only one of the two paſſages, leading to it, can be brought under the eye of the obſerver. See Ear. The varieties of deafneſs have been uſually treated by writers under ſeparate heads, according to the parts of the organ, in which the cauſes were ſituated; as in the *meatus externus*, or external paſſage; the euſtachian tube, or paſſage to the internal ear; and the internal ear itſelf.

1. *Deafneſs from Diſeaſe of the external Paſſage.*—The moſt common impediment to hearing that occurs in the external paſſage to the ear, conſiſts in an unuſual accumulation and inſpiſſation of the cerumen, or wax of the ear, which is ſecreted by the glands of the paſſage. The quantity of cerumen, which may be collected without injuring the power of hearing, cannot be ſtated: it is different in different individuals, and in many perſons the quantity is naturally conſiderable. Sometimes it has been obſerved plugging up the paſſage altogether; and ſometimes forming a falſe membrane of the tympanum, or thickening the natural one. But in ordinary caſes, where the proper conſiſtence of the cerumen

remains unaltered, the functions of the organ are not much injured; whereas a ſmall portion of hardened cerumen, lodged on the membrane of the tympanum, will deprive a perſon of his hearing. The ſymptoms connected with the hardening of the cerumen are pretty well known. The patient, beſides his inability to hear, complains of noiſes, particularly a claſh or confuſed ſound, in maſtication, and of heavy ſounds like the ponderous ſtrokes of a hammer. Where the relation of theſe ſymptoms excites a ſuſpicion of the exiſtence of hardened wax, the practitioner will have recourſe to examination, by which he may reduce it to a certainty. Any means capable of removing the inſpiſſated wax may be adopted; but ſyringing the paſſage with warm water is the moſt ſpeedy and effectual, and the only expedient neceſſary.

The external paſſage is ſubject to an ulceration, which has been termed herpetic. This produces a great thickening of the integuments, and the paſſage is often ſo much cloſed, that a great degree of deafneſs enſues. The ichor, which exudes from the ulcerated ſurface, inſpiſſates in the paſſage, and not only obſtructs the entrance of ſound, but is accompanied with much fœtor. This diſeaſe is not unfrequent. It generally yields to the application of ſolutions of the metallic ſalts, as of muriated mercury in lime water; or of vitriolated zinc; or to the uſe of the unguentum hydragyri nitratum; calomel, or other alteratives being taken at the ſame time. Saunders on the Ear.

Sometimes polypous excreſcences occur in the external paſſage, and impede the hearing; or the paſſage is rendered narrow by the preſſure of the neighbouring glands, when much ſwelled; and ſometimes it is obſtructed by the preſence of extraneous ſubſtances. The cauſes, in the firſt and laſt inſtances, may be removed by mechanical means.

2. *Deafneſs from Obſtruction of the Euſtachian Tube.*—The euſtachian tube is a paſſage leading from behind the palate to the internal cavity of the ear. By permitting a free motion of the air, contained in that cavity, during the vibration of the membrane of the tympanum, it facilitates that vibration, and conſequently contributes greatly to the perfection of the faculty of hearing. Hence a very great degree of deafneſs is produced by an obſtruction of this tube. When ſuch an obſtruction has occurred, air can no longer be admitted into the cavity of the tympanum; and the included portion either is abſorbed, or it remains. In the latter caſe, the included air, incapable of yielding in any other way than by condenſation, counterbalances the pulſes excited by ſounding bodies. In the former, the preſſure of the atmoſphere will carry the membrane of the tympanum into the tympanum, as far as it will go, in which ſtate it will reſt, and cannot vibrate in any conſiderable degree. Either hypotheſis will account for the deafneſs. But it has been ſuggeſted, that, ſubſequently to the obliteration of the euſtachian tube, the included air is abſorbed, and the cavity of the tympanum filled with mucus; at leaſt the cavity was found in this ſtate in two inſtances of diſſection, where the euſtachian tube was cloſed. See Saunders on the Anatomy and Diſeaſes of the Ear, p. 42.

The obſtruction of the tube moſt frequently ariſes from ſyphilitic ulcers in the throat, or ſloughing in the cynanche maligna. The deafneſs enſues on the healing of the ulcers, that is, when the obſtruction is complete. The deſcent of a naſal polypus into the pharynx, and enlarged tonſils, have alſo been known to cloſe the tube.

If the patient blows, with his noſe and mouth ſtopped, he does not experience that peculiar ſenſation, which ariſes from the inflation of the tympanum. He ſpeaks only of the loſs of ſenſe, and complains of no particular ſymptom. The deafneſs differs in this reſpect from all other ſpecies; the patient not being haraſſed with diſtreſſing noiſes, which are falſe perceptions, ariſing from a diſeaſed ſtate of the auditory nerves, or proceeding from real impreſſions on the nerves produced by morbid cauſes in the organ.

Generally the obſtruction comes on in conſequence of ſome notable diſeaſe in the throat, and the cartilaginous extremity of the tube is moſt commonly the ſeat of it; yet it occaſionally takes place in the bony portion. It is then ſlower in its progreſs, proceeds from no obvious cauſe, and conſiſts in an inordinate oſſification, filling up the canal.

We are deſtitute of a perfect diagnoſtic ſymptom, by which we can be aſſured when deafneſs is produced by an obſtruction of the euſtachian tube. The incapability of inflating the tympanum only renders it probable; for many people who hear perfectly, are incapable of producing this ſenſation, at leaſt in a great many trials. We are therefore compelled to truſt to the patient's account. This will be ſufficient when the obſtruction has been preceded by an ulceration or diſeaſe of the throat.

We are indebted to the penetration of Mr. Aſtley Cooper, for the means of reſtoring the ſenſe of hearing, which the obſtruction deſtroys. He had obſerved in ſuppurations of the tympanum, which had injured and even deſtroyed the membrane of the tympanum, that the ſenſe of hearing was only impaired, not totally loſt, and that the degree of deafneſs, when the membrana tympani was only injured, by no means equalled that produced by the obſtructed tube. Reflecting on this, he was induced to conſider that a ſmall puncture of the membrane of the tympanum would be of trivial detriment even to a ſound ear, and in this inſtance would be the means of reſtoring to the organ the exerciſe of its functions. This happy expedient he himſelf executed with great ſucceſs, a ſucceſs fully confirmed by a ſimilar reſult of the operation in the hands of others.

The operation is performed by paſſing an inſtrument into the external paſſage, and puſhing it through the anterior and inferior part of the membrane of the tympanum. It is unneceſſary to ſtate the reaſon for making the puncture in this place; the poſition of the manubrium of the malleus evidently demands this precaution. A little crack will immediately be perceived, ſimilar to what is occaſioned by the puncture of parchment, more particularly if the tube be cloſed, as the ſound will then be more acute, from the rapid entrance of the air through a narrow aperture. The inſtrument ought not to penetrate far into the tympanum, leſt it ſhould penetrate its vaſcular lining; as the eſcape of blood into the cavity would for a ſhort time fruſtrate the operation, even if it ſhould ultimately be ſucceſsful.

When the puncture has been ſucceſsfully made, the patient is inſtantaneouſly reſtored to a perfect hearing. The effect of the operation is the immediate ſubſtitution of a ſmall hole in the membrana tympani for the euſtachian tube; and air being admitted into the tympanum, the mobility of the membrane returns, and the action of the machinery of the tympanum is re-eſtabliſhed.

The only obſtacle to the complete ſucceſs of this puncture is its tendency to cloſe. For this reaſon, it is often neceſſary to make rather a large hole in the membrane, before you can inſure the patient againſt the recurrence of the deafneſs. But a large hole diminiſhes the perfection of the ſenſe. Tenſion is the ſtate eſſential to the membrane of the tympanum. This tenſion is not diminiſhed by a ſmall perforation; but if the membrane be much lacerated or detached at its circumference, the tenſion will be leſſened; yet even then the patient receives a ſtriking benefit. To this imperfection we muſt however ſubmit; and perhaps a larger opening may generally be expedient, than can be made by a

ſimple

ſimple perforation with the inſtrument propoſed by Mr. Cooper.

The caſes related by Mr. Cooper may be found in the Philoſophical Tranſactions for 1802. See Saunders on the Ear, p. 41, *et ſeq.*

3. *Deafneſs from Diſorders of the internal Ear.*—The nature of the deafneſs which ariſes from diſeaſes of the internal parts of the ear is much more difficult to aſcertain, than in the preceding inſtances, in conſequence of our inability to examine the morbid changes, which are the immediate cauſe of the defect. If we reflect on the component parts of the labyrinth, we are led to conjecture that the deafneſs originates in a want of ſenſibility in the nerve; in ſome alteration in the ſtructure of the membranes on which the nerve is expanded; or in a change in the properties of that fluid, which is contained in the membranes, and is the immediate agent in impreſſing the ſentient extremities of the nerve. In diſſecting the ear of a perſon born deaf, Mr. Clive found that the labyrinth, inſtead of its aqueous fluid, contained a thick caſeous ſubſtance. This muſt have been incapable of undulating in the cavities of the labyrinth, and its exiſtence is fully adequate to account for the total abſence of the ſenſe. Examples have been mentioned by writers of hydatids in the cavities of the internal ear, and of collections of pus and blood in thoſe parts, producing deafneſs; alſo of exoſtoſis, and other alterations of the internal ſtructure of the organ, occaſioned by the virus of ſmall-pox, ſcrofula, &c. See Portal, Anatomie Medicale, tom. iv.

But it has been aſcertained by diſſection, that total deafneſs may exiſt, without any defect in the mechaniſm of the exterior parts of the ear; and without any defect in the membranous ſtructure on which the nerve is expanded, in the water it contains, or in the nerve itſelf; in ſhort, without any morbid appearance that can be traced by the eye. Such caſes may be conſidered as examples of nervous deafneſs, dependent on ſome morbid inſenſibility in the nerve itſelf. The patient can inflate the tympanum, and the external paſſage may be perfectly free from hardened wax; this ſpecies too is accompanied with the ſenſation of different noiſes in the head, ſuch as the murmuring of water, the ruſtling of leaves, the blowing of wind, &c. Some patients complain of a beating noiſe, correſponding with the pulſe, increaſing by bodily exertion in the ſame degree as the action of the heart. The cauſe of this ſenſation is doubtleſs the pulſation of the arteries; although it may be difficult to explain what the change is, which renders the organ ſuſceptible of this impreſſion; or to determine whether the ſmall arteries, which ramify in the interior of the labyrinth, are the immediate agent, or the internal carotid, which paſſes cloſe beneath the cochlea.

The inſenſibility of the auditory nerves may be occaſioned by various diſorders of the parts in their courſe; as by the preſſure of tumours, exoſtoſis of membranes thickened by inflammation, by ſcrofula, or ſyphilis, or by mere fullneſs and over-diſtenſion of the blood-veſſels: hence deafneſs of this ſort often precedes or accompanies apoplexy, palſy, epilepſy, phrenitis, &c. A ſimilar deafneſs likewiſe ariſes, where the organic cauſe is ſeated in the brain, or ſpinal marrow, at the origin of the auditory nerves; and ſometimes in the ſide oppoſite to the deaf ear. See Portal Anat. Medicale—Calliſen Syſt. Chirurg. Hodiern. tom. ii. par. 359, and 551.

Where there are ſymptoms of plethora, ſuch as intimate a probable occurrence of hemiplegia, or where local inflammation in the head has preceded the deafneſs, evacuants, particularly local ones, will be reſorted to; ſuch as the application of bliſters to the neck or behind the ears, or of leeches, or cupping glaſſes, to the ſame parts; and the general antiphlogiſtic plan will be purſued more or leſs, according to the urgency of the plethoric ſymptoms. Where theſe ſymptoms are abſent, and a ſuſpicion of the thickening and enlargement of the neighbouring parts, in conſequence of ſyphilitic or ſcrofulous affections, exiſts; the conſtitutional remedies required for theſe diſeaſes will be employed. And where it appears that the ſenſibility of the auditory nerves is impaired from a feeble and imperfect action of the circulation, the local ſtimulus of electricity, or galvaniſm, may be applied; ſtimulating liquids may be dropped into the external meatus, or introduced on lint, and ſternutatories employed, together with the external ſtimulus of veſicatories and rubefacients.

Confirmed nervous deafneſs is, in truth, generally hopeleſs; but it is not eaſy to determine *à priori*, when attempts to cure it will be vain. This does not depend on the duration of the diſeaſe, but on the degree of miſchief done to the organ; and therefore the periods at which it becomes incurable muſt be various. In the incipient ſtate, it would appear, from ſeveral caſes related by Mr. Saunders, that the nervous deafneſs may be relieved by the antiphlogiſtic regimen, purgatives, and bliſtering. On the Anat. and Diſeaſes of the Ear, p. 49, *et ſeq.*

Another diſorder of the internal ear, producing deafneſs, is a puriform diſcharge from the tympanum, of an ichorous nature, ſometimes tinged with blood, and imparting a yellow colour to a ſilver inſtrument. This diſeaſe is attended with a loſs of hearing proportionate to the injury which the machinery of the tympanum has ſuſtained; and hence the ſenſe is variouſly impaired, from the ſlighteſt degree up to total deafneſs.

In general, when the patient blows ſtrongly, with the noſe and mouth cloſe, air will be expelled at the meatus externus. Whenever this circumſtance is obſerved, it is clear that the diſcharge proceeds from, or is connected with, an injury or deſtruction of the membrane of the tympanum; but the reverſe by no means proves that the membrana tympani is found, and the diſcharge therefore confined to the external paſſage. For it often occurs, that the ſame inflammation, which terminates in a ſuppuration of the tympanum, previouſly obliterates the euſtachian tube, which remains permanently cloſed after the ceſſation of the inflammation that occaſioned it. The ſtate of the tympanum, therefore, muſt be aſcertained by actual examination. The ear muſt be inſpected in a ſtrong light. For this purpoſe the patient ſhould be placed in ſuch a poſition, that the rays of the ſun may fall into the meatus, and illuminate it ſufficiently to make the bottom viſible: or the ear may be ſounded with a blunt probe, and any perſon acquainted with the particular feel of the membrana tympani, may eaſily diſtinguiſh it by the touch. If the membrane be defective, the inſtrument will paſs into the tympanum, the bony ſuperfices of which is ſtill more diſtinguiſhable. He, therefore, who will inſtitute a proper examination, cannot fail of arriving at a certain knowledge of this diſeaſe, and will not confound it with the herpetic ulcerous ſtate of the meatus externus, before mentioned. In the latter ſucceſs is certain, and as ſoon as the ulceration is cured, hearing is perfectly reſtored; but in the former, however perfectly the diſcharge may be ſuppreſſed, the event is very dubious.

This ſtate of the tympanum is produced by various cauſes. In the ſcarlatina maligna, inflammation of the tympanum attacks the patient, and advances to gangrene: if he ſurvives the fever, the machinery of the ear often ſloughs ſo extenſively, that the membrana tympani and the whole chain of bones are evacuated, and the patient is perfectly deaf. Moſt commonly this diſeaſe ſucceeds the ear-ache, which is, in fact, an acute inflammation of the tympanum. If the inflammation ſhould not ſubſide ſpontaneouſly, or be aſſuaged by art, the tympanum and maſtoid cells form a large quantity

tity of pus. After the patient has ſuffered the moſt intenſe pain, the membrane of the tympanum ulcerates, and the pus is diſcharged at once in a large quantity. He is then greatly relieved, but the diſeaſe ceaſes not; the parts ſupply freſh matter, which continually oozes out at the meatus.

The ſymptoms produced by inflammation of the tympanum are, moſt intenſe pain of the head and ear, a great degree of ſymptomatic fever, and ſometimes ſlight delirium. This pain fluctuates, and its paroxyſms reſemble the toothache; a reſemblance which has unfortunately cauſed it to be wholly neglected, or very improperly treated. The caſe obviouſly requires the moſt active antiphlogiſtic treatment, and the abſence of every thing ſtimulative. But the oppoſite practice prevails. The moſt acrid applications and ſpirituous liquors are the general means employed for the relief of the patient; an error that unqueſtionably tends to produce the worſt cataſtrophe that can happen, *viz.* the ſuppuration of the parts. This diſeaſe, however, is not always the reſult of one acute attack of inflammation: moſt frequently it is ſlower and more inſidious in its progreſs. Slight paroxyſms of pain attack the patient, and are relieved by ſlight diſcharges. Theſe recur at intervals, until at laſt the puriform diſcharge is fully confirmed.

This diſeaſe demands attention, as it is very deſtructive in its tendency to the faculty of hearing, ſince it rarely ſtops, till it has diſorganized the tympanum. For the puriform diſcharge naturally advances to ulceration, and ulceration to denudation and caries of the bone, and ſeparation of the chain of bones: a caries of the tympanum is therefore ultimately produced. Yet it is unaccountable that many writers and practitioners aſſert the propriety of abſtaining from all attempts to ſtop this diſcharge, from a notion that the ſuppreſſion of it might be injurious. But the fact is, the puriform diſcharge from the tympanum often exiſts without a caries of the bone, and antecedently to this is moſt commonly curable.

Mr. Saunders conſiders this diſeaſe as exiſting under three ſtates or ſtages: 1. a ſimple puriform diſcharge; 2. a puriform diſcharge, complicated with fungi and polypi; 3. a puriform diſcharge with a caries of the tympanum. The time neceſſary to accompliſh the tranſition from one ſtage to another is uncertain. Years do not affect it in ſome inſtances; and, in others, it ſeems to advance almoſt at once to a carious ſtate of the bone.

The puriform diſcharge from the tympanum is a local diſeaſe, and does not depend on any diſordered ſtate of the conſtitution: general remedies are therefore inefficacious. But as a bad ſtate of health is unfavourable to the healing of any parts, ſo, in this particular complaint, any diſordered condition of the habit ſhould be corrected. The chief dependence is to be placed on direct applications to the parts affected. Injections of vitriolated zinc, acetite of lead, &c. are very efficacious in ſuppreſſing the diſcharge; and their effects may be aided by the external employment of bliſters and ſetons. The fungous and polypous excreſcences muſt be removed or deſtroyed by mechanical means; they are only incidental occurrences, and their removal reduces the diſeaſe to the firſt ſtage.

As it has been ſtated that the degree of deafneſs produced by this complaint is various; ſo, when it is cured, the ſenſe is reſtored in different degrees. For the deafneſs during its continuance is ſometimes very conſiderable, when the real injury which the organ has ſuſtained is trivial. In the firſt ſtage, the mere thickening of parts, or the collection of the diſcharge, muſt impede the action of the intervening machinery between the external and internal parts of the ear: and, in the ſecond, the mechanical obſtruction of the funguſes or polypi excludes the pulſes of the air. On this account there is often a notable increaſe of the power of hearing, when the diſcharge is ſuppreſſed in the firſt and ſecond ſtages. But as the parts are inviſible, it is difficult, if not impracticable, to decide *à priori* how far the power of hearing can be reſtored. Now this is no valid objection to attempting the cure. The ſenſe will not be rendered worſe by a failure; and, if the diſcharge ſhould be ſtopped, the diſeaſe which cauſed it is removed, the organ ſafe from farther injury, and the patient freed from an offenſive malady. In the laſt ſtage, the ſenſe is almoſt, if not totally, deſtroyed; and although the diſcharge be ſtopped, the patient's hearing will be very little, if at all, improved.

After the cure of this diſeaſe, the tympanum is expoſed to the free ingreſs and egreſs of the air, and the mucilaginous diſcharge inſpiſſates, as the mucus of the noſe, by the exhalation of its watery parts. By this accident the patient's deafneſs increaſes at intervals, for which he often ſeeks relief. The practitioner, on ſounding the ear, perceives this hardened matter; and conceiving, as is really the caſe, that it produces the augmentation of deafneſs, is tempted to remove it. But nothing ſtimulative, nor any rude attempts can be ſafe, for there is great danger of reproducing the diſcharge. Having learned that a diſcharge has pre-exiſted, it will be expedient to leave it to a ſpontaneous ſeparation. Saunder's Anat. and Diſ. of the Ear.

Deafneſs often occurs in the courſe of acute fevers, in conſequence, perhaps, of the loſs of power in the nervous ſyſtem, which ſucceeds the violence of febrile excitement. Experience has decided, that this deafneſs is a favourable ſymptom, conſidered with a view to the prognoſis in fever, and that it generally ceaſes as the ſtrength is reſtored.

The deafneſs common in old age depends upon the condition of the nerves and ſolids, which conſtitutes the decline of the conſtitution; for in this ſtate the ſolids become rigid, and unfit for delicate movements, and the ſenſibility of the nerves is greatly diminiſhed. Of courſe it is incurable.

Thoſe who are born deaf continue, through life, deprived of the faculty of ſpeech; as it is impoſſible they ſhould learn to imitate ſounds which they cannot hear. Much ingenuity and induſtry, however, have been exerted, and that with conſiderable ſucceſs, in ennabling theſe unhappy beings to communicate their thoughts to each other. See DUMBNESS.

In the year 1792, an "aſylum for the ſupport and education of the deaf and dumb children of the poor," was inſtituted in London, which has afforded relief to a conſiderable number of theſe very compaſſionable objects. This ſociety is under the direction and management of a preſident, 14 vice-preſidents, a treaſurer, and a committee of 23 governors. The children, who are admitted between the age of 9 and 14 years, are taught to ſpeak and write articulately, and to underſtand what they read and ſpeak; they are taught penmanſhip, and practical arithmetic, ſo as to fit them for the management of common concerns; and they are alſo taught ſome of the moſt uſeful mechanical arts, by which they are enabled to earn a livelihood.

Thoſe born deaf are alſo dumb, as not being able to learn any language, at leaſt in the common way. However, as the eyes, in ſome meaſure, ſerve them for ears, they may underſtand what is ſaid by obſerving the motion of the lips, tongue, &c. of the ſpeaker; and even accuſtom themſelves to move their own, as they ſee other people do; and by this means learn to ſpeak.

Thus it was that Dr. Wallis taught two young gentlemen, born deaf, to know what was ſaid to them, and to return pertinent anſwers. Digby gives us another inſtance of the ſame, within his own knowledge. And there was a Swiſs phyſician formerly living at Amſterdam, one Joh. Conrad

Conrad Amman, who effected the ſame in ſeveral children born deaf, with ſurpriſing ſucceſs. He has reduced his ſcheme to a fixed art, or method, which he has publiſhed in his Surdens Loquens, Amſtelod, 1692, and De Loquela, ibid. 1700.

In the Philoſoph. Tranſ. N° 312. we have an account by Mr. Waller, R. S. Sec. of a man and his ſiſter, each about fifty years old, born in the ſame town with Mr. Waller, who had neither of them the leaſt ſenſe of hearing; yet both of them knew, by the motion of the lips only, whatever was ſaid to them, and would anſwer pertinently to the queſtion propoſed. It ſeems they could both hear and ſpeak when children, but loſt their ſenſe afterwards; whence they retained their ſpeech, which, though uncouth, was yet intelligible.

Such another inſtance is that of Mr. Goddy's daughter, miniſter of St. Gervas in Geneva, related by biſhop Burnet. At two years old they perceived ſhe had, in great part, loſt her hearing; and ever after, though ſhe heard great noiſes, yet ſhe could hear nothing of what was ſaid to her. But by obſerving the motions of the mouths and lips of others, ſhe had acquired ſo many words, that out of theſe ſhe had formed a ſort of jargon, in which ſhe could hold converſation whole days with thoſe that could ſpeak her language. She knew nothing that was ſaid to her, unleſs ſhe ſaw the motion of the mouths of thoſe that ſpoke to her; ſo that, in the night, they were obliged to light candles to ſpeak to her. One thing will appear the ſtrangeſt part of the whole narration: ſhe had a ſiſter, with whom ſhe had practiſed her language more than with any body elſe; and in the night, by laying her hand on her ſiſter's mouth, ſhe could perceive by that what ſhe ſaid, and ſo could diſcourſe with her in the dark. Burn. Let. iv. p. 248.

It is obſervable that deaf perſons, and ſeveral others thick of hearing, hear better and more eaſily, if a loud noiſe be raiſed at the time when you ſpeak to them, which is owing, no doubt, to the greater tenſion of the ear-drum on that occaſion. Dr. Willis mentions a deaf woman, who, if a drum were beat in the room, could hear any thing very clearly; ſo that her huſband hired a drummer for a ſervant that by his means he might hold converſation with his wife. The ſame author mentions another, who, living near a ſteeple, could always hear very well, if there was a ringing of three or four bells; but never elſe.

Dr. Buchner relates an extraordinary method of making deaf perſons to hear, by applying thin ſlips of wood, about ſix feet long, an inch broad, and as thick as the back of a knife, at one end to the upper teeth of the ſpeaker, and at the other to the upper teeth of the deaf perſon. Many trials were made to aſcertain the fact, and the voice was found perceptible and diſtinct. This method, he obſerves, may be adapted to all perſons afflicted with deafneſs, provided the auditory nerves are not injured or deſtroyed at their origin. See Buchner's Eaſy and Practicable Method to enable deaf Perſons to hear, tranſlated from the German, 1770. For a further account of the deaf and dumb, and of the methods uſed for the relief of ſuch perſons, ſee DUMBNESS.

A man who is born deaf, dumb, and blind, is regarded by the law in the ſame ſtate as an idiot; being ſuppoſed incapable of any undertaking, as wanting all thoſe ſenſes which furniſh the mind with ideas. A man who could neither ſpeak nor hear, committed felony and was arraigned, and therefore committed to priſon. A perſon, having made his will, became ill and loſt his ſpeech: the ſame will was delivered into his hands, and it was ſaid to him, that he ſhould deliver it to the vicar, if it ſhould be his laſt will, or otherwiſe retain it: he delivered it to the vicar, and it was held a good will. When a defendant appeared by oath, to be both ſenſeleſs and dumb, ſo that he could not inſtruct his counſel to draw his anſwer, it was ordered that no attachment, or other proceſs of contempt, ſhould be awarded againſt him for not anſwering, without ſpecial order of the court. One that is deaf cannot give; and thus alſo, one that is dumb. However, according to the opinion of ſome, they may conſent by ſigns; but it is generally held, that a dumb perſon cannot make a gift, becauſe he cannot conſent to it. (1 Inſt. 107.) The lord ſhall have the cuſtody of a copyholder that is deaf and dumb; for elſe he ſhall be prejudiced in his rents and ſervices; and adjudged for the grantee of the lord againſt the prochain amy of the copyholder. Cro. Jac. 105.

A perſon born deaf and dumb, who ſignified by ſigns that ſhe underſtood what ſhe was about to do, was allowed to levy a fine of lands; by Bridgman, Ch. J. and other juſtices. Cart. 53.

DEAL, is a well-known kind of wood of great uſe. In its common ſtate, for ordinary purpoſes, it conſiſts of planks of fir, ſawed from the trunk of the tree longitudinally, of various thickneſſes, according to the uſes to which they are applied.

A very good method of ſeaſoning planks of deal, is to throw them into ſalt-water as ſoon as they are ſawed, and keep them there three or four days, frequently turning them. In this caſe they will be rendered much harder, by drying afterwards in the air and ſun; but neither this nor any other means yet known, will preſerve them from ſhrinking.

Deals are imported chiefly from Chriſtiania, and other parts of Norway; from Dantzic, and ſeveral parts of Pruſſia; from Peterſburg, Archangel, and other parts of Ruſſia. They are ſold by the piece, or ſtandard hundred, or long hundred of 120. A ſtandard, or reduced deal, is 1½ inch thich, 11 inches wide, and 12 feet in length.

Rods of deal expand laterally, or acroſs the grain, in moiſt weather, and contract again in dry; and thence have been found to make an uſeful hygrometer. Phil. Tranſ. N° 480. p. 184. See HYGROMETER.

DEAL, in *Geography*, is a market and ſea-port town in the hundred of Cornilo, and lathe of St. Auguſtine, in the county of Kent, England. It is diſtant 18 miles from Canterbury, and 73¾ S.E. from London. The town ſtands on the ſea-ſhore, which here forms a bold beach; and is defended from the violence of the waves by a long rampart of pebbles, which have been thrown up by the ſea. The pariſh is recorded in the domeſday book under the name of Addelam. In the time of Henry VI., it was, by the king's letters patent, conſigned, together with Walmer, to the juriſdiction of the Cinque Ports. At that time it was governed by a deputy and aſſiſtants, appointed by the mayor and jurats of Sandwich. This mode continued till the eleventh year of William III., A. D. 1699, when the people ſucceeded in obtaining a charter; by which Deal was conſtituted "a free town and borough of itſelf, and its local government veſted in a mayor, twelve jurats, twenty-four common-council-men, a recorder, town clerk, and other inferior officers. Nothing, however, appears in this charter to have abrogated the preſcriptive rights of Sandwich, in ſome inſtances, reſpecting Deal. The former has a concurrent juriſdiction with the latter; and the inhabitants of Deal are liable to ſerve on juries at Sandwich. In the time of Leland, this place did not rank as a town; it was, according to that author, no more than a ſmall "fiſher village, half a myle fro the ſhore of the ſea," inhabited by a few perſons employed in fiſhing, whoſe houſes conſtitute that part of the town called Upper Deal. What

is termed Lower Deal received a great increaſe in extent of buildings and population, about the commencement of the laſt century. It is now a conſiderable maritime town, conſiſting of three long ſtreets, running parallel with the ſea, and connected by others more or leſs narrow; which, as is common in ſea-ports, render them both incommodious and dirty. The houſes are irregularly built, principally of brick; but in thoſe erected within a few years, greater attention has been paid to uniformity. Since the year 1790, when an act was obtained for paving, lighting, and cleanſing the town, it has undergone various improvements; and convenient regulations have been made for the accommodation of perſons viſiting the place during the bathing ſeaſon. The mother-church being found too ſmall, and inconveniently diſtant, a chapel of eaſe was erected in the lower town by ſubſcription, in the year 1707. The caſtle, which ſtands to the ſouth of the town, is ſurrounded by a deep foſs, croſſed by a draw-bridge. It conſiſts chiefly of a round tower, containing apartments for the officers and garriſon who attend the battery. But the principal defence of this place is derived from the martello towers, and other batteries which have been lately erected along the coaſt in the vicinity. In the town is a regular cuſtom-houſe, at a little diſtance from which is a naval ſtore-houſe. Here are alſo an extenſive naval and military hoſpital, and a large houſe of induſtry. The ſea immediately oppoſite the town is called the Downs, which has become a general rendezvous for ſhipping, both men of war, as well as merchant veſſels. This has contributed greatly to the increaſe of Deal. In time of war, the immenſe influx of people, and the conſtant demand for ſhip-ſtores, tackling, proviſions, clothes, and various other neceſſary articles, render this town an eligible ſituation for perſons in trade. But the principal inhabitants are employed in maritime occupations, and ſome few are engaged in ſmuggling. The channel called the Downs is about eight miles long and ſix broad; and the depth varies from eight to twelve fathoms. This is the common rendezvous of the Eaſt India and other fleets on their voyages, both when homeward and outward bound. In particular ſtates of wind, nearly 400 ſail of ſhipping have been ſeen at one time, ſafely riding at anchor here. For the more ſafe conveyance of veſſels in and out of the Downs, and up the river Thames and Medway, an eſtabliſhment of pilots is formed at this port, under an act of parliament. They are divided into two claſſes, called the upper and lower book. The former conſiſts of twenty-four pilots, five of whom are conſtituted wardens; and the latter, of twenty-five. The charges of pilotage are regulated by the tonnage. Thoſe of the upper book have the privilege to pilot ſhips drawing more than eleven feet four inches. To this book, thoſe of the lower progreſſively riſe by ſeniority. Attached to theſe is a ſet of experienced and intrepid ſeamen, who make it their particular buſineſs to afford aſſiſtance to ſhips in diſtreſs. They are called Hovellers. During a ſtorm, when the wind ſeems to baffle all human ſkill, and nothing but inſtant deſtruction is expected by the labouring veſſels; two or more hovelling boats will be frequently ſeen riding upon the boſom of the wave, as if in defiance of the contending elements. Numerous are the inſtances in which the brave crews of theſe apparently inſignificant veſſels, have been ſucceſsful in reſcuing thouſands from the moſt imminent peril.

According to Gale, Horſley, and ſome other antiquaries, the place of Cæſar's firſt landing in Britain was at Rutupiæ, the preſent Richborough; but Camden, and the authors of the Beauties of England and Wales, conclude that it muſt have been near Deal. After mentioning the advantageous poſition the Britons had taken on the heights of Dover, and convinced of the folly of attempting a landing there, Cæſar ſtates, in his Commentaries, which contain his own account of his campaigns, "Dato ſigno et ſublatis anchoris circiter millium paſſuum viii., ab eo loco progreſſus aperto, et plano littore naves conſtituit;" *i. e.* having made a ſignal, weighed anchor, and ſailed eight miles further up, he brought to his ſhips on a plain and open ſhore. A deſcription which agrees with the coaſt near Deal, for it is the firſt low ſhore to the north of Dover; and ſome entrenchments, ſtill to be traced, are ſuppoſed the ſite of his maritime camp. At this place Perkin Warbeck landed from France, when he perſonated the duke of York, under which title he laid claim to the crown of England.

The amount of the population of Deal, as returned under the late act, was 5420, and the number of houſes 917. By the charter of king William, two weekly markets are held on Tueſdays and Wedneſdays, and two annual fairs. Haſted's Hiſt. of Kent. Beauties of England and Wales.

The Goodwin ſands, called by Hector Boethius, "Navium gurges & vorago, a moſt dreadful gulf and ſhip-ſwallower;" though they ſerve as a kind of natural pier, and form the ſouthern boundary of the Downs, are frequently fatal to ſhips coming from the eaſtward; as the waves break over them in boiſterous winds with unabating fury. Theſe ſands extend about ten miles in length, from what is termed the northſand-head, being nearly oppoſite to Ramſgate; and the ſouthſand-head, to Kingſdown. Tradition has repreſented theſe ſands as once an iſland, which belonged to the great earl Godwin, and that it ſuddenly ſunk, and was ſwallowed by the ſea, as a ſignal mark of divine vengeance on the heinous ſins of that nobleman. But from Gyraldus' account and that of Hector Boethius, the event appears to have more naturally happened about the end of the reign of William Rufus, or beginning of Henry the I.'s, and was occaſioned by one of thoſe ſudden inundations, which, from ſome latent cauſes, not unfrequently happen in the ocean; whereby the ſtate of its ebbings and flowings is conſiderably changed upon different coaſts. Hiſtory informs us, ſuch a phenomenon took place on the coaſts of Flanders, whereby a large tract of country was overflowed; and, at the ſame time, a ſimilar injury, though not to an equal extent, was done on the ſhores of England and Scotland. The preſent ſtate of the ancient Portus Rutupenſis, and of Sandwich haven, afford ſtriking evidence of the ſea having formerly flowed much higher than it does at preſent on this part of the coaſt. The danger of ſtriking on the ſands is deſcribed by Mr. Seaton to ariſe from their nature, which is that of a "quickſand, clean and unconnected;" yet lying ſo cloſe, as to render it difficult to work a pointed bar to the depth of more than ſix or ſeven feet. At low water they are dry in many parts, and parties frequently land on them; but when the tide begins to flow, the ſand becomes ſoft and quick, and their ingurgiting power is ſo great, that the largeſt veſſel driven upon them would, in a ſhort time, be completely ſwallowed up. To prevent ſuch accidents, the corporation of the Trinity-houſe intended to have erected a light-houſe upon theſe ſands; but no foundation being obtained by boring, the deſign was laid aſide. A floating light has been placed on the eaſt ſide of the north ſand-head, which has proved highly beneficial. Beauties of England and Wales, vol. viii. Perambulation of Kent. Hiſtorical Report of Ramſgate Harbour.

About one mile ſouth of Deal is ſituated Walmer, at the commencement of the high ſand, which extends from hence to the cliffs at Dover. The village is commonly called Walmer-ſtreet, and conſiſts of good houſes, inhabited by reſpectable families. Walmer caſtle ſtands at a ſhort diſtance from the village, nearly cloſe on the ſea ſhore; and commands, from its windows, a beautiful view of the

Downs, and the coaſt of France. This fortreſs is appropriated for the reſidence of the Warden of the Cinque-ports; and for this purpoſe, a few years ago, the principal apartments were handſomely fitted up for Mr. Pitt, on his temporary retirement from the chancellorſhip of the exchequer.

DEAL, a town of America, in the ſtate of New Jerſey, and county of Monmouth, 7 miles S. of Shrewſbury, to which the inhabitants of Philadelphia reſort, in ſummer, for health and pleaſure.

DEAMBULATORY, or AMBULACRUM, from *deambulo*, a lobby or portico for walking in, anciently very common in thoſe hoſpitals or other ſimilar buildings which were not furniſhed with regular cloiſters. One of theſe deambulatories, in length half a furlong, is to be ſeen on the eaſt ſide of the hoſpital of St. Croſs, near Wincheſter.

DE AMICIS, ANNA, in *Biography*, an exquiſite female Italian ſinger and actreſs, arrived in England in the autumn of 1762, with her family, all engaged for the comic opera, but all in ſubordinate parts, except herſelf, who was appointed firſt woman, to ſupply the place of the Paganini.

The opera-houſe opened this ſeaſon, Nov. 18th, with the comic opera of "Il Tutore e la Pupilla," a paſticcio, in which Anna De Amicis captivated the public in various ways. Her figure and geſtures were in the higheſt degree elegant and graceful; her countenance, though not perfectly beautiful, was extremely high-bred and intereſting; and her voice, and manner of ſinging, exquiſitely poliſhed and ſweet. She had not a motion that did not charm the eye, or a tone but what delighted the ear. Indeed, ſhe acted and ſung for the whole family; for by her merits, and good works, ſhe covered the multitude of their ſins, which would otherwiſe have had no remiſſion.

In Jan. 1763, a new comic paſticcio was brought on the ſtage, called "La Caſcina," and in February, another comic opera, compoſed by Galuppi, called "La Calamita de' Cuori," which had in it ſome charming airs, that ſeem to have been originally intended for the diſplay of all the enchanting powers of the young Anna De Amicis. Of this burletta, as well as the preceding, the elegant and intereſting De Amicis was the chief ſupport. The reſt of the ſinging was ſo deſpicable, that only her ſongs have been printed.

This admirable performer, on her return to Italy, in 1764, was engaged at Milan, as firſt ſerious woman, in which character ſhe ſung at the minor theatres of Italy with univerſal admiration, till 1773, when ſhe was again called to Milan, previouſly to her departure to Peterſburg, whither ſhe went in 1774. In 1775 ſhe was engaged at Naples, and in 1776 we find her ſinging in the ſame city, with Pacchierotti, under the name of De Amicis Buonſolazzo, probably the name of her huſband. And from this time ſhe ſeems to have regarded Naples as her home; as, except once at Turin with Aprile, in 1777, and the next year at Bologna with Tibaldi, we hear of her nowhere elſe, and her private conduct ſeems to have been equally correct with her public; as no irregularities have ever arrived at our knowledge to ſully her profeſſional fame and amiable character.

DEA NETTLE, a name provincially applied to the weed, wild hemp.

DEAN, a prime dignitary in moſt cathedral and collegiate churches; being uſually the preſident of the chapter.

He is called dean, decanus, of the Greek δεκα, *ten*, as being ſuppoſed to preſide over ten canons or prebendaries, at leaſt.

Canoniſts diſtinguiſh between deans of cathedral, and thoſe of collegiate churches. The firſt, with their chapter, are regularly ſubject to the juriſdiction of the biſhop. As to deans of collegiate churches, they have uſually the contentious juriſdiction in themſelves, that is, they exerciſe juriſdiction over their canons in all civil or criminal matters; though ſometimes this belongs to them in common with the chapter.

In England, as there are two foundations of cathedral and collegiate churches, the old and the new (the latter being thoſe founded by Henry VIII. on the ſuppreſſion of the abbots and priors, when their convents were turned into dean and chapter); ſo there are two ways of creating the deans. Thoſe of the old foundation, as the deans of St. Paul's, York, &c. are raiſed to their dignity much like a biſhop; the king firſt ſending out his conge d'elire to the chapter; the chapter then chooſing, the king yielding his royal aſſent, and the biſhop confirming him, and giving his mandate to inſtal him. Thoſe of the new foundation, as the deans of Canterbury, Durham, Ely, Norwich, Wincheſter, &c. are donative, and are inſtalled by a ſhorter courſe; only by the king's letters patent, without either election or confirmation, and are viſitable only by the lord chancellor, or by ſpecial commiſſion from the king; but the letters patent are preſented to the biſhop for inſtitution, and a mandate for inſtallment goes forth. 1 Inſt. 95. Davis, 46, 47. The new deaneries and chapters to old biſhoprics are eight; *viz.* Canterbury, Norwich, Wincheſter, Durham, Ely, Rocheſter, Worceſter, and Carliſle. The new deaneries and chapters to new biſhoprics are five; Peterborough, Cheſter, Glouceſter, Briſtol, and Oxford.

Deaneries and prebends may become void, like a biſhopric, by death, by deprivation, or by reſignation to either the king or the biſhop. If a dean, prebendary, or other ſpiritual perſon, be made a biſhop, all the preferments of which he was before poſſeſſed are void; and the king may preſent to them in right of his prerogative royal. But they are not void by the election, but only by the conſecration.

There are ſome cathedral churches which never had a dean; as thoſe of St. David and Landaff, where the biſhop is the head of the chapter, and in his abſence the archdeacon. The biſhop is deemed "quaſi decanus," and has, it is ſaid, both an epiſcopal throne and a deaconal ſtall allotted to him in the choir. St. Aſaph and Bangor, the two other Welſh cathedrals, have the dignity of dean diſtinct from that of biſhop; but the patronage of both deaneries is in the reſpective biſhops, theſe being neither elective by the chapter, nor donative in the crown. 1 Inſt. 95. In Ireland the king appoints to deaneries as to biſhoprics, by letters patent. *Id. ib.*

Conſtantine, we are told, erected an office of nine hundred and fifty perſons at Conſtantinople, taken out of divers trades and profeſſions, whom he exempted from all impoſitions, and beſtowed them on the cathedral church, to render the offices of burial gratis to the defunct, particularly to the poor. Theſe he called decani and lecticarii, probably becauſe they were divided by tens, each whereof had a bier, or a litter, to carry the bodies in. It is ſuppoſed to be thoſe who, under Conſtantius, began to be called copiatæ; *i. e.* clerks deſtined for labour; for they are uſually ranked among the clerks, and even before the chantors. By a law of the year 357, it appears that there were ſome of theſe copiatæ at Rome.

DEAN is alſo a title applied among us to divers perſons that are the chiefs of ſome peculiar churches, or chapels; as, the dean of the king's chapel, who has no juriſdiction; of the arches, who has juriſdiction only; of Battel, in Suſſex, founded by William I. who hath cure of ſouls, and juriſdiction within the liberty of Battel, is preſentable by the duke of Montagu, and inſtituted and inducted by the biſhop of Chicheſter, but not ſubject to his viſitation: of Bocking, in Eſſex, who hath a court and juriſdiction to hold plea of all eccleſiaſtical matters ariſing in ſeveral pariſhes within his peculiar,

peculiar, and is conſtituted by commiſſion from the archbiſhop of Canterbury, like the dean of Arches, and of Croydon in Surrey. There are alſo deputy-deans and commendatory-deans, who cannot confirm any grants, &c.

A commendatory dean may, with the chapter, chooſe a biſhop; and if a dean be elected biſhop, and before conſecration obtains diſpenſation to hold his deanery *in commendam*, ſuch dean may well confirm, &c. for his old title remains, and therefore confirmations, and other acts done by him as dean, are good in law. Latch. 237, 250. Palm. Rep. 460. A deanery is a ſpiritual dignity, and therefore a man cannot be dean and prebendary in the ſame church. Dyer, 273.

Deans of colleges in our univerſities are officers appointed to ſuperintend the behaviour of the members, and to enforce diſcipline. Some are called deans of provinces, or deans of biſhops: thus, the biſhop of London is dean of the province of Canterbury; and to him, as ſuch, the archbiſhop ſends his mandate for ſummoning the biſhops of his province, when a convocation is to be aſſembled, which may perhaps account for his being called dean of the biſhops. Deans are divided, from the nature of their office, into deans of ſpiritual promotions, and deans of lay promotions. Of the former kind are deans of peculiars, with cure of ſouls, deans of the royal chapels, deans of chapters, and perhaps rural deans. Of the latter kind are deans of peculiars, without cure of ſouls, who may be, and frequently are, perſons not in holy orders.

Deans, with regard to the manner of their appointment, are elective, ſuch as deans of chapters of the old foundation, nominally ſo, like biſhops; donative, as the deans of chapters of the new foundation, deans of the royal chapels, deans of peculiars without cure of ſouls, dean of the arches, appointed by commiſſion from the archbiſhop of Canterbury; preſentative, as ſome deans of peculiars with cure of ſouls, and the deans of ſome chapters of the new foundation, if not all; the dean of Battel, the dean of Glouceſter, preſented by the king to the biſhop, with a mandate to admit him, and to give orders for his inſtallment, and deans by virtue of another office, as the biſhop of London is dean of the province of Canterbury, and the biſhop of St. David's is dean of his own chapter.

DEAN, *Rural*, or *Urban Dean*, was formerly an eccleſiaſtical perſon, who had a diſtrict of ten churches, or pariſhes, either in the country or city, within which he exerciſed juriſdiction. Theſe rural deans were ſometimes called archipreſbyteri; and at firſt they were, both in order and authority, above the archdeacons. They were at firſt elected by the clergy, and by their votes depoſed; but afterwards they were appointed and removed, at the diſcretion of the biſhop; and hence they were called decani temporarii, to diſtinguiſh them from the cathedral deans, who were called decani perpetui. They ſeem to have been deputies of the biſhop, ſtationed round his dioceſe, the better to inſpect the conduct of the parochial clergy, to inquire into and report dilapidations, and to examine the candidates for confirmation, and therefore armed with an inferior degree of judicial and coercive authority.

We meet with rural deans as early as the ninth century. Hincmar, in a capitular to his archdeacons, reſerves the right of electing them to himſelf; and only allows it to the archdeacons, in caſe he be abſent, and by proviſion only. Some take the rural deans to hold the rank and place of the chorepiſcopi. Be this as it will, it is certain they are very ancient in France, Germany, and England; though, till the end of the ſixteenth century, they were unknown in Italy; becauſe the biſhoprics being there exceeding ſmall, they were not needed. St. Charles Borromeo is ſaid to have firſt introduced them there. Their office is now wholly extinguiſhed in England, the authority which they had being executed by the archdeacons and chancellors of biſhops; though their deaneries ſtill ſubſiſt as an eccleſiaſtical diviſion of the dioceſe, or archdeaconry.

DEAN, in the ancient monaſteries, was a ſuperior eſtabliſhed under the abbot, to eaſe him in taking care of ten monks; whence he was called decanus, in imitation of thoſe officers called by the ſame name among the Romans, who had ten ſoldiers under them.

The monaſteries being now leſs populous than they were in ancient times, the abbot, or prior, does not ſtand in ſo much need of being eaſed; ſo that theſe *deans* are, in general, ſet aſide.

DEAN *and Chapter*. Anciently, biſhops did not ordinarily tranſact matters of moment "ſine conſilio preſbyterorum principalium," who were then called "ſenatores eccleſiæ," and colleagues of the biſhops; repreſented, in ſome meaſure, by our chapters of cathedrals, wherein the dean and ſome of the prebends are, upon the biſhop's ſummons, to aſſiſt him in ordinations, deprivations, condemnations, excommunications, and other weighty concerns of the church, both religious and ſecular.

When the reſt of the clergy were ſettled in the ſeveral pariſhes of each dioceſe, theſe were reſerved for the celebration of divine ſervice in the biſhop's own cathedral. The dean and chapter are the nominal electors of a biſhop. The biſhop is their ordinary and immediate ſuperior; and has, generally ſpeaking, the power of viſiting them, and correcting their exceſſes and enormities. At common law they had a check on the biſhop; for till the ſtatute 32 Hen. VIII. c. 28. his grant or leaſe would not have bound his ſucceſſors, unleſs confirmed by the dean and chapter. Co. Litt. 103. See BISHOP, and CHAPTER.

DEAN, MICHEL, in *Geography*, a market town in the county of Glouceſter, England, is ſituated in the foreſt of Dean; diſtant weſt from Glouceſter 12 miles, and from London 120. Its name is derived from the Saxon words *dene* and *micl;* the former alluſive to its ſituation in a deep dell; and the latter ſignificant of its former importance, or its relative extent to a village, called Little Dean, in the neighbourhood. This place is principally noticed for its fine church and handſome ſpire. The body is quadrangular, conſiſting of a nave, chancel, two north, and one ſouth aiſles; which, from having variouſly ſhaped arches, appear to have been built at different periods. The roof is of oak, and its ceiling finely ſtudded with roſes and other well carved devices. In the eaſt window of one of the north aiſles are ſome remains of figures in ſtained glaſs, with which formerly the church appears to have been finely decorated. The font, which Mr. Lyſons ſuppoſes was cut out of the capital of ſome ancient column, appears as old as the twelfth century. Adjoining the ſouth aile, riſes a handſome tower, terminated by a well proportioned octagonal ſpire; which meaſures from the foundation, 156 feet in height.

Though the principal town in the foreſt, it is an inconſiderable and ill-built place; formed by three ſmall ſtreets, uniting in the ſhape of the letter Y. Formerly it was a ſtaple for wool, and had a conſiderable manufacture of cloth; but at preſent the only trade conſiſts in the ſale of leathers, and the making of pins. It has a market weekly, on Mondays, and two annual fairs. The number of houſes, as returned under the late act, amounted to 125, of inhabitants 563. In the vicinity of Michel Dean are the remains of *Flaeley Abbey*, once a highly privileged, and celebrated monaſtery of Ciſtercians; founded in the reign of king Stephen, by Roger Fitz-Milo, ſecond earl of Hereford, on the ſpot where his brother, while hunting, had accidentally been killed

killed by a random arrow. Henry the ſecond beſtowed on it ſeveral manors, an iron forge, and two oaks weekly out of the royal foreſt, to ſupply the forge with fuel. In the ſucceeding reign, this grant, having been found prejudicial to the foreſt, was revoked, and a wood conſigned in lieu of it. At the time of the diſſolution the annual revenues were valued at 112*l.* 13*s.* 1*d.* The abbey was granted to ſir Anthony Kingſton. The abbot's lodge was in tolerable preſervation ſo late as the year 1777, when a conſiderable part of it was deſtroyed by fire. The remainder having received many additions, forms the manſion of the preſent proprietor of the eſtate, ſir Thomas Crawley Boevy, bart. The floor of the chapter-houſe was diſcovered a few years ago, at a ſmall depth beneath the ſurface in the garden, and ſeven "ſtone coffin-lids," probably flat ſtones, were dug up, ſculptured with ornamental croſſes. In the church is an inſcription to the memory of Mrs. Catherine Boevy, who died in 1726; for whom a cenotaph, commemorative of her virtues, was erected in Weſtminſter abbey. Rudge's Hiſtory, &c. of Glouceſterſhire, 2 vols. 8vo.

Dean, *Foreſt of*, in Glouceſterſhire, England, includes nearly the whole of that part of the county, comprehended between the river Severn on the eaſt, the river Wye on the ſouth-weſt, and Herefordſhire on the north. By perambulations, made in different reigns, its extent was limited. The quantity of lands belonging to the crown, at preſent, appears to be 23,015 acres; excluſive of other property, which individuals have obtained by grants, or encroachments. It was formerly twenty miles in length, and ſo full of wood, as to make it dangerous for travellers to paſs through it, from the ſhelter it afforded to banditti. Formerly it afforded ſuch excellent oak, and in ſuch quantities, fit for the navy, as to be juſtly the glory of our own country, and the envy of other nations. For it is ſtated, that the officers who commanded the Spaniſh armada had expreſs inſtructions, after they had made good their landing, to proceed to the deſtruction of our foreſts; particularly that of Dean, in Glouceſterſhire. This grand reſource has almoſt failed. By the improvident grants of different ſovereigns, the neglect of the foreſt officers, and injudicious fellings, without adequate planting and fencing, to encourage the growth of young timber; ſuch depredations have taken place, and are ſtill committing, that threaten its annihilation as to the purpoſes of the navy. At preſent it ſupplies the royal dock yards, annually, with about 1000 loads of timber. In its preſent ſtate and management, the foreſt is divided into ſix walks, and the government veſted in a lord-warden, who is by virtue of his office conſtable of St. Briavel's caſtle; ſix deputy wardens; four verderors, who are choſen by the freeholders; a conſervator; ſeven woodwards; a chief foreſter in fee; a gaveller; and a ſteward of the ſwainmote. Theſe officers are empowered to hold a court of attachment every forty days, and another court called the juſtice ſeat, once in three years. Theſe courts are held at the ſpeech houſe, or king's lodge, which is ſituated near the centre of the foreſt. The whole being extra-parochial, and the inhabitants exempted from many taxes, with liberty of paſturage, and the privilege of ſinking mines, has induced many perſons to take up their reſidence here. The free miners and colliers not only claim a right to dig for iron ore and coal, but, with the conſent of the gaveller, to be ſupplied with timber for their reſpective works. The ſixth part of the produce from each mine belongs to the crown, and the annual compoſition for this, paid to the gaveller, is called the king's gawl. The crown poſſeſſes the excluſive right alſo of keeping in the foreſt 800 deer; but from various cauſes theſe are become ſo ſcarce, that the annual royal warrant, iſſued for four bucks and four does, is frequently returned unexecuted. The general appearance of the foreſt is beautiful and pictureſque, containing riſing grounds interſperſed with deep vallies, abounding in places with fine coppices and orchards. The new roads lately made by virtue of an act, granted in the 36th year of his preſent majeſty, have greatly facilitated the means of travelling through it. According to the account of ſir Robert Atkins, the foreſt only contained the ſix lodges, which were erected for the keepers; but, according to the returns under the late act of parliament, the number of houſes within it was 720, and the population amounted to 3325.

Dean *River*, or *Newark dyke*, in Nottinghamſhire, is, in fact, a ſide branch of the Trent river, (which here has two channels,) paſſing cloſe under the walls of Newark caſtle; it is navigable for about three miles, from the Trent river, to the town of Newark, has two locks upon it, and boats of 50 tons can navigate it; the exports thereon are corn, wool, Coddington paving-ſtone, (blue lias,) and plaſter-ſtone or gypſum; the imports are coals, principally from the Derbyſhire pits at Codnor-Park, and Ilkeſton; in Nottinghamſhire, at Brinſley, Bigarlee, and Eaſtwood; and Yorkſhire, at Park-Gate and Bradford; the latter for the blackſmiths' uſe; Crich and Burrow lime are alſo imported, with deals, iron, &c., for the uſe of the town of Newark, and ſurrounding country. There is a ſtone bridge of ſeven arches over the Dean at Newark, from whence the York road is embanked, acroſs the iſland or meadows in the Trent vale to Murkham, having 72 arches under the ſame, for the paſſage of the flood waters of this impetuous river. See Canal.

DEANE, Edmond, in *Biography*, brother to the biſhop of Oſſory, was born at Saltonſtall, in Yorkſhire, in 1572. At the age of nineteen he was entered at Merton college in Oxford, and having continued there, and at St. Alban's Hall, until he was admitted doctor in medicine, he went and ſettled at York. In 1626, he publiſhed, at London, "Spadacrene Anglica, or the Engliſh Spaw Fountain," being a brief ireatiſe of the acid or tart fountain in the foreſt of Knareſborough, in Yorkſhire. In a later edition, there are accounts of other mineral waters found in the foreſt. "Admiranda Chymica, Tractatulus, cum Figuris," 8vo. Frankford, 1630. This has been ſeveral times reprinted. Sam. Norton, Wood ſays, was eſteemed half author of this book, there being in it ſome of his tracts; ſc. Catholicon phyſicorum, Mercurius redivivus, &c. Dean is ſuppoſed to have died about the time the civil wars broke out, but in what year is not known. Wood's Athenæ Oxon.

DEARADERE, in *Geography*, a river of European Turkey, in Bulgaria, which runs into the Mariza near Demotica.

DEARNE and Dove Canal, is the parliamentary name of a navigable canal in Yorkſhire, between the Don river, a few miles below Rotherham, to the Barnſley canal, near the town of Barnſley, with ſide-cuts to Rockcliff bridge, and to Cob-car Jng; it ſerves for the export of the coals and iron of the great run of coals along which it paſſes. See Canal.

DEARTICULATION, in *Anatomy*. See Diarthrosis.

DEATH, in *Phyſiology*. "Death," ſays Dr. Johnſon, "is the ſeparation of the ſoul from the body." However correct this definition may be deemed, in a moral or religious point of view, we cannot admit it as ſufficiently preciſe for the purpoſes of the phyſician and phyſiologiſt. We ſhould propoſe to define it as "the irrecoverable ceſſation of all the functions which belong to a living animal." By this explanation

nation we diſtinguiſh *death*, 1ſt, from all thoſe conditions of the body in which any particular function or functions are deſtroyed, while the reſt remain in a more or leſs unimpaired ſtate: 2dly, from *ſuſpended animation*, in which the vital powers are merely interrupted, and may be reſtored to a ſtate of activity within a certain period of time: and 3dly, from *putrefaction*, which denotes the chemical changes taking place in the conſtituent ingredients of the *dead* body.

Living bodies are particularly diſtinguiſhed from inorganic matter by the mode in which their exiſtence is terminated; and hence a termination by *death* becomes one of the grand characteriſtics of *life*. The duration of an inorganized ſubſtance is dependent merely on the kind of compoſition which determines its phyſical ſolidity; hence it muſt be eſtimated from the bulk and coheſion of each body, and muſt be limited only by the nature and connection of its component parts. In living machines, on the contrary, the term of exiſtence is neceſſarily confined, and is not at all influenced by their compoſition or ſize. For many large and robuſt animals do not laſt ſo long as others much weaker and ſmaller. There are alſo relations of ſize between living and inorganic bodies totally at variance with thoſe of their reſpective duration, ſince in many inſtances particles of extreme ſmallneſs are infinitely more durable than the moſt bulky animals or vegetables.

The duration of inorganic bodies muſt always be influenced by the media in which they exiſt, and by the agents which ſurround them; but living beings are governed by very different laws. Their exiſtence is not limited by the natural corruptibility of their component elements, but is protracted, although by the nature of their formation, they tend rapidly to diſſolution, to a much longer period than that tendency would have led us to expect. Liable, by their very eſſence, to decay and decompoſition, they laſt much longer than they would have done, had their duration been determined by the properties of their elements. It is prolonged by their internal active powers, to which there is nothing analogous in inorganized ſubſtances. Definitions of life have been drawn from various abſtract and limited conſiderations; the following general view will exhibit a more ſatisfactory explanation of the ſubject: "life is the aſſemblage of thoſe functions which reſiſt death." Every thing which ſurrounds living bodies tends to deſtroy them. They are continually acted upon by inorganic ſubſtances; while at the ſame time they exert a conſtant and mutual influence on each other; they would ſoon yield, if they did not poſſeſs a permanent principle of re-action: life is that principle; unknown in its eſſence, it can only be appreciated by its phenomena; the moſt general of which is an habitual alternation of action on the part of external bodies, and of re-action on that of the living body, the proportions of which vary at different ages. The infant poſſeſſes an exceſs of life, ſince the re-action exceeds the action; they are nearly in a ſtate of equilibrium in the adult. The re-action of the internal principle diminiſhes in old age, while the influence of external agents remains the ſame; at that time the powers of life languiſh and advance inſenſibly to their natural termination, which takes place when all proportion has ceaſed.

Death then is the inevitable condition to which all bodies, that have poſſeſſed life, muſt ſooner or later be reduced. The exact period of its approach may indeed be accelerated or retarded by various cauſes; but the improved knowledge of modern times, in the compoſition of our bodies, in the powers by which they are animated, and in the laws by which theſe are governed, has clearly ſhewn that human exiſtence, however prolonged for a few ſhort years by attention to the circumſtances that promote bodily health and ſtrength, muſt at laſt arrive at its term. It has convinced every reflecting and reaſoning mind, that there cannot poſſibly be any means of protracting human life beyond a certain point; and that the attempts to diſcover an elixir of youth and immortality are to be reckoned among thoſe chimeras, which have too often employed the time, and bewildered the minds of the human ſpecies.

Natural death is remarkable on this account, *viz.* that the functions of animal life, or thoſe which connect the individual with the external world, conſiſting of ſenſation, motion, and ſpeech, ceaſe long before the functions of organic life, or thoſe by which its exiſtence is maintained, as reſpiration, digeſtion, abſorption, circulation, ſecretion.

The man who dies at the concluſion of an advanced age expires in detail. His external functions gradually ceaſe; the ſenſes are loſt in ſucceſſion, the ordinary ſtimuli no longer producing any effect on the organs. The ſight becomes obſcure and imperfect, and ſoon ceaſes altogether to tranſmit objects to the ſenſorium. The hearing, feeling, and ſmelling, are loſt in the ſame way. The taſte ſtill remains awhile, as the ſituation of its organ connects it with the organic as well as the animal life. Thus, when every agreeable ſenſation is loſt, and the ties which connected the old man to external objects, are nearly all deſtroyed, this alone remains, and is the laſt thread upon which the enjoyment of exiſtence is ſuſpended. The inactive ſtate of the organs of ſenſe is quickly ſucceeded by a loſs of the functions of the brain. Perception ſoon decays, when the ſenſes ſupply no matter for its exertion; and the power of imagination follows. The memory of recent occurrences is loſt, becauſe the ſenſes, weakened, and almoſt dead, tranſmit them imperfectly to the brain. Paſt tranſactions are ſtill often remembered with tolerable exactneſs. Hence the old man judges only according to the ſenſations which he has experienced heretofore; while the child is influenced ſolely by his preſent feelings; and the judgment in either caſe muſt be equally uncertain.

As the interruption of the functions of the brain is a neceſſary conſequence of the nearly total annihilation of external ſenſations, ſo it affects, in its turn, the powers of locomotion and ſpeech. The brain, being acted on by the ſenſes, re-acts on the muſcles in a proportionate degree. The motions of the old man are few and ſlow; it is with difficulty that he quits his accuſtomed attitude. Seated near the fire, which affords an agreeable ſource of warmth to his languid frame, he paſſes whole days retired, in a manner, within himſelf. Unintereſted in what ſurrounds him, a ſtranger to all deſires, paſſions, and ſenſations; ſpeaking little, becauſe he has no inducement to ſuch exertion, he is happy to feel that he ſtill exiſts, when he is loſt to almoſt every other feeling.

Are we juſtified in conſidering a rigid ſtate of the muſcles, and diminiſhed power of contraction in thoſe organs, as another cauſe of the inactivity of old age? This very probably has ſome influence, but we cannot conſider it as a leading cauſe, ſince the heart and inteſtines muſt partake of the ſame affection of their ſtructure, although they do not loſe the power of motion equally with the voluntary muſcles. The latter, therefore, do not loſe the *power*, but the *cauſe* which ſhould bring that into action, *viz.* the influence of the brain. If it were poſſible to unite in the ſame perſon the brain and ſenſitive organs of the old man with the muſcles of a youth, the voluntary motions would not be more energetic than in the old ſubject, becauſe there would ſtill be wanting a cauſe to excite the power into action.

From the preceding view, it appears that the external functions are gradually extinguiſhed in the old man; and that the animal life is almoſt annihilated, whilſt the organic ſtill retains its activity. At this time, the ſtate of the man who is about

to periſh by a natural death, approximates to that of the fœtus in utero, or of the vegetable, which lives only internally, and has no perception of external objects.

This inequality in the duration of the two lives is, in a certain degree, advantageous to the human ſpecies, as it diſengages the individual gradually from thoſe ties which connect him to ſurrounding objects, and thus alleviates the regret with which he would otherwiſe contemplate the hour, when theſe bonds are to be finally ſevered. The thought of death is painful only becauſe it terminates our animal exiſtence, and thereby extinguiſhes all thoſe functions which keep up our relations to the external world. It is nothing but the interruption of thoſe functions, that makes us look on death with feelings of fear and regret. We do not dread the ſuffering of bodily pain; for moſt perſons on their death-bed would gladly embrace the offer of a lengthened exiſtence, even although it were purchaſed by uninterrupted ſuffering.

The wearieſt and moſt loathed worldly life,
That age, ache, penury, and impriſonment can lay on man,
Is paradiſe to what we fear of death.

Could we imagine to ourſelves an individual, in whom death ſhould affect the internal functions only, as circulation, digeſtion, ſecretion, &c., leaving the animal life ſtill in vigour; ſuch a man would contemplate with indifference the approaching end of his organic exiſtence, becauſe he would feel that the pleaſures of life are not attached to that, and that he would ſtill be able to feel and enjoy almoſt every thing which formerly conſtituted his happineſs. Since then the animal life ceaſes by degrees; ſince each of the ties, which connects us to the pleaſure of living, is broken very gradually, this pleaſure leaves us at laſt almoſt imperceptibly, and we have already become inſenſible to the value of life, before it is terminated by the ſtroke of death. This is the courſe of things that we obſerve in the old man, who paſſes, by the ſucceſſive and partial loſs of his external functions, to the cloſe of his exiſtence. His death is that of a vegetable, which, having no relations to external objects, and no conſciouſneſs of life, can have none of death.

The organic exiſtence, which ſtill remains to the old man after the almoſt entire loſs of the animal life, ends in a very different manner from what we obſerve in violent and ſudden deaths. In the latter we may diſtinguiſh two periods: the firſt, which is marked by the ſudden ceſſation of reſpiration and circulation, two functions which ceaſe in theſe caſes nearly as ſoon as the animal life; the ſecond, which comes on more ſlowly, is the gradual termination of the organic functions. The digeſtive juices ſtill act on the contents of the ſtomach, which even retains, in ſome degree, the power of propelling the food. Abſorption, as numerous experiments have ſhewn, ſtill goes on for ſome time. And inſtances are by no means rare, where the bladder and rectum, by the irritable power which their coats ſtill retain, expel the urine and fæces ſome time after the apparent period of a ſudden death. Nutrition is ſtill manifeſted in the hair and nails; and, together with ſecretion, would no doubt be equally obvious in other parts, if we had the power of obſerving thoſe inſenſible motions in which theſe functions conſiſt. Animal heat is preſerved in moſt ſudden deaths, and particularly in aſphyxia, much beyond the time which would be neceſſary for the diſſipation of that, which the body, conſidered as a maſs of dead matter, contains at the inſtant of apparent diſſolution.

Many other facts might be adduced, to prove, in concurrence with thoſe already ſtated, that the organic functions terminate ſlowly and gradually in ſudden deaths; that the harmony of the internal life, conſidered as a whole, is firſt affected in theſe caſes; that the general circulation and reſpiration are firſt arreſted, but that the other vital organic proceſſes are ſucceſſively and ſlowly extinguiſhed. In the natural concluſion of old age, on the contrary, life ceaſes, becauſe each function has been terminated in detail. The active powers gradually deſert each organ; digeſtion languiſhes; ſecretion and abſorption are arreſted; the capillary circulation becomes troubled, and being deprived of the tonic powers, which preſide over it, ſtops. The general circulation is then ſuſpended in the large veſſels; and laſtly, the contractions of the heart ceaſe; ſo that this part is rightly termed the *ultimum moriens*. We may therefore bring the differences, which exiſt between the death from old age, and that which ariſes from ſudden cauſes, into the following view. In the former, life is firſt extinguiſhed in the parts, and then ceaſes in the heart; ſo that the influence of death is exerted from the circumference to the centre. In the latter, it ceaſes firſt in the heart, and then in all the parts: ſo that the phenomena of death take place from the centre to the circumference.

Having thus deſcribed the manner in which death takes place, when it occurs as the natural cloſe of life, we proceed to conſider the mode of its occurrence when it appears before the time allotted by nature as the cloſe of our exiſtence. So powerful indeed is the influence exerted by ſociety, that individuals of the human ſpecies ſeldom arrive at that period. Animals generally reach it; but the ceſſation of exiſtence, produced by mere old age, has become with us a rare phenomenon. Accidental death becomes, therefore, an object particularly worthy of our attention. This may take place in two ways; either as the ſudden reſult of a great diſturbance excited in the animal economy, or as the ſlow and gradual termination of diſeaſe. In the former caſe, as for inſtance in apoplexy, great hemorrhage, concuſſion, aſphyxia, we can inveſtigate the laws, which regulate the termination of the different functions; becauſe the organs of the body are unaffected, and ceaſe to act by the influence of cauſes directly the reverſe of thoſe which kept them in exertion in the natural ſtate: now, as the latter are partly underſtood, they naturally lead us to a knowledge of the former. We can, moreover, imitate theſe kinds of death on animals, and are thus enabled to analyſe their various phenomena by the way of experiment. In the caſe of diſeaſes, neither of theſe methods is open to us; we cannot produce them artificially, nor are we ſufficiently acquainted with the nature of thoſe morbid changes which occur in the vital powers, when the body is under the influence of diſeaſe, to reaſon on them with any preciſion. The firſt remark ſuggeſted to us by the obſervation of various ſpecies of ſudden death, is, that in all inſtances the organic functions may ſtill ſubſiſt for a certain time, after thoſe of animal life have been annihilated: while, on the contrary, the latter never ſurvive the termination of the former. An individual who has ſuffered compreſſion of the brain, or who has been attacked by apoplexy, ſtill lives internally for ſeveral days after he has ceaſed to exiſt for external objects. If, on the contrary, death attacks any eſſential organic function, as the circulation in caſes of wounds or aneuriſmal ruptures of the heart, reſpiration in the different kinds of aſphyxia, &c. thoſe functions are ſuddenly terminated, but the animal life ends at the ſame inſtant. Even here a part of the organic proceſſes ſtill continues for a greater or leſs length of time, and ends only by degrees. Theſe obſervations are of the firſt importance in a practical point of view, as leading us to the exertions we make uſe of in inſtances of apparent death from hanging, drowning, ſuffocation,

cation, &c. They teach us that the loſs of ſenſation and voluntary motion, together with a ceſſation of reſpiration and of the heart's action, are by no means ſure indications of death; that the powers of life ſtill exiſt under theſe circumſtances, and may be again called into action by the employment of proper means; and that ſuch caſes are, therefore, well deſcribed by the term of *ſuſpended animation*.

A warm-blooded animal never continues to exiſt externally after its internal life has ceaſed; ſo that the ceſſation of the organic phenomena is a ſure ſign of general death. We can, indeed, decide on the reality of ſuch death only by this criterion, ſince the ſuſpenſion of the external functions is almoſt always an uncertain ſign.

This difference in the termination of the two lives ariſes from the kind of influence which they exert on each other, from the ſpecies of connexion which unites them. For though they are diſtinguiſhed by numerous characters, their principal functions are connected by a reciprocal influence. This bond of union ſeems to exiſt between the brain on one ſide, for the animal, and the lungs or heart on the other, for the organic life. The action of any one of theſe three organs is eſſentially neceſſary to that of the two others. When, therefore, one ceaſes to act, the others muſt likewiſe be arreſted; and as they are the three centres, in which all the ſecondary phenomena of the two lives terminate, theſe phenomena muſt be inevitably annihilated, and general death enſue.

Phyſiologiſts of all ages have recognized the importance of this triple centre; and have almoſt univerſally beſtowed the name of *vital functions* on thoſe which reſide here: becauſe life is immediately connected with them, while its relations to the proceſſes, ranged under the heads of natural and animal functions, are much leſs intimate.

All ſudden deaths muſt begin by the interruption of circulation, reſpiration, or the action of the brain. One of theſe three functions ſtops firſt, and the others terminate ſucceſſively. The ſeries of phenomena, which occur in theſe caſes, has been admirably developed in the "Recherches phyſiologiques ſur la vie et la mort" of Bichât. We ſhall have occaſion to notice ſeveral of his experiments and remarks in the articles relating to phyſiology; and ſhall therefore confine ourſelves, on the preſent occaſion, to a ſketch of the general concluſion which he draws from them.

Death beginning in the heart: exemplified in the rupture of an aneuriſm, in a wound of the heart, or large blood-veſſels, &c. For want of the excitation, which the brain receives from the heart, its action ſtops; and conſequently ſenſation, locomotion, and the voice, are immediately interrupted. Beſides, the organs of theſe functions would ceaſe to act, for want of the excitement derived from the blood, even if the brain could ſtill exert its influence. The individual, therefore, exiſts no longer for ſurrounding objects after the inſtant in which his heart is dead. The interruption of the organic functions, which has commenced with the circulation, goes on at the ſame time with reſpiration. When the brain has ceaſed to act, there are no longer any mechanical phenomena exhibited in the lungs; ſince the diaphragm and intercoſtal muſcles are under its influence. The chemical phenomena ceaſe alſo, when the heart no longer receives or ſends the materials neceſſary for their developement. General death then comes on in a gradual way, by the ſtoppage of the ſecretions, of exhalation, and nutrition.

Death beginning in the Lungs.—When the mechanical phenomena of the lungs are interrupted, the following is the ſeries in which the other functions ceaſe. 1. Interruption of mechanical phenomena. 2. Ceſſation of chemical phenomena for want of the air which ſupports them. 3. Annihilation of the brain's action through the deficiency of excitement by the red blood. 4. Extinction of animal life; becauſe its organs are no longer excited by the brain and the arterial blood. 5. Ceſſation of the general circulation: 6. And of the capillary circulation, ſecretion, abſorption, and exhalation, for want of the influence of red blood on the organs of thoſe functions. 7. Interruption of digeſtion, through the want of ſecretion, and through the non-excitation of its organs, &c.

The phenomena of death occur in a different ſucceſſion, when the chemical functions of the lungs are interrupted; as in animals placed in vacuo, in ſtrangulation, in drowning, and in breathing non-reſpirable gaſes.

1. Interruption of chemical phenomena. 2. Suſpenſion of the brain's action. 3. Ceſſation of ſenſation, locomotion, the voice, and the mechanical phenomena of reſpiration. 4. Stoppage of the action of the heart, and of the general circulation. 5. Termination of the capillary circulation, ſecretion, exhalation, abſorption, and, conſequently, of digeſtion. 6. Diſſipation of the animal heat, which reſults from all the functions, and which does not leave the body till they have all ceaſed. In whatever function death may begin, it is always by this that it ends.

Death beginning in the Brain.—1. Annihilation of the action of the brain. 2. Sudden ceſſation of ſenſation and voluntary motion. 3. Paralyſis of the diaphragm and intercoſtal muſcles. 4. Interruption of the mechanical phenomena of reſpiration: 5. And of the chemical phenomena. 6. Admiſſion of black blood into the ſyſtem which ſhould convey red blood. 7. Retardation of the circulation from the contact of this blood with the heart and arteries, and by the abſolute immobility of all the parts, and particularly of the cheſt. 8. Death of the heart, and ceſſation of general circulation. 9. Interruption of organic functions, eſpecially in parts uſually ſupplied with red blood. 10. Abolition of animal heat.

Although in the three kinds of death, which we have juſt noticed, the functions may be annihilated ſuddenly, yet ſome of the vital powers ſtill remain in the parts for a certain length of time. Organic ſenſibility and contractility (the powers which preſide over the organic functions) are ſtill very manifeſt in the muſcles of both claſſes; and the muſcles of the animal life ſtill exhibit very clearly a ſuſceptibility of galvanic agency. This permanence of the organic properties is nearly the ſame in all caſes; the only cauſe which gives riſe to any difference, is the more or leſs gradual mode in which life has been extinguiſhed. In proportion to the rapidity of the death, is the contractility energetic, and ſlow in diſappearing. Where the functions have been gradually extinguiſhed, this property is ſo much the leſs ſuſceptible of being brought into action.

General Deſcription of Death.—The uſe of the hands, eyes, and feet generally is impaired in old perſons ſome time before death; the ſenſes fail; the bowels are torpid; the pulſe ſlow and intermittent; ſleep or dozing frequently occurs; and the laſt portions of the urine are not expelled from the bladder. The ſpeech becomes embarraſſed; the head cannot be held up; and the hands no longer execute the commands of the will. Laſtly, reſpiration becomes laborious, ſlow, interrupted, and ſtertorous; the diſtreſs excites an effort to breathe, which the debility renders nearly ineffectual. Some time before death, the heart is manifeſtly unable to drive the blood through the arteries into the veins; ſo that it is collected after death in the former veſſels. The blood then deſerts the feet, which

grow

grow cold; and the heat retreats upwards with the blood, which may be obſerved in experiments to be driven no farther than the groin; there it reaches no farther than the kidneys, and there is a reflux, driving it back through the ſpace in which it had juſt before been urged forwards. The flux and reflux then reach ſucceſſively no farther than the diaphragm, the eighth or ſixth ribs, and the arch of the aorta. Laſtly, the blood flows back upon the heart itſelf. This viſcus now reſts for a ſhort time, and then makes an effort to free itſelf from the contained blood. The impoſſibility of driving this through the lungs creates a ſenſe of anxiety, which gives riſe to the laſt ſtruggle of departing life. The heart's action and reſpiration are imperfectly performed for a few times at irregular intervals, till at laſt the accumulated blood is no longer a ſufficient ſtimulus, and the ſenſibility and contractile power of the organ are finally loſt. Reſpiration ceaſes by a ſtrong expulſion of air from the cheſt, often accompanied with a ſigh or groan, and ariſing, perhaps, partly from the action of the expiratory muſcles, and partly from the natural effect of the elaſtic powers reſiding in the parietes of the thorax. Hence, in common language, to *expire* has become ſynonymous with to *die*. The action of the left ventricle ceaſes firſt, as the obſtruction of reſpiration cuts off its ſupply of blood. The right ventricle then ceaſes to act, although it ſtill receives blood from the venæ cavæ. The auricle even now palpitates for a while, and receives and repels the blood alternately with the venæ cavæ, till it alſo grows inſenſible to the ſtimulus.

The muſcles are relaxed at the moment of death; ſo that the limbs fall into that poſition to which the force of gravity would naturally bring them. Hence, the mouth is uſually open from the dropping of the under jaw; and all the members of the body are eaſily bent and moved in every direction. Sooner or later, however, a very different ſtate of the muſcles ſucceeds: they become firmly contracted, and bring the whole body into a moſt rigid ſtate; ſo that no part can now be moved, without the application of a very great force. They remain in this ſtate until the natural progreſs towards putrefaction again ſoftens their fibres. Phyſiologiſts regard this phenomenon, together with that of the coagulation of the blood, as ariſing from the laſt exertion of that reſidue of vital power, which the body retains after the period of apparent diſſolution. It does not take place in an invariable manner in all kinds of death. In animals killed ſuddenly by lightning, or by a powerful electrical ſhock, the body does not ſtiffen, nor does the blood coagulate; this is explained by ſtating that the vital principle is totally and ſuddenly extinguiſhed over the whole body in ſuch kinds of death; and that the moment of *apparent diſſolution* is alſo that of *abſolute univerſal death*. We are alſo informed that theſe changes do not take place in the bodies of animals killed by wounding the medulla ſpinalis; and that where this method of ſlaughtering them for food is practiſed, the meat may be dreſſed the ſame day, without being found tough. (Adams on Morbid Poiſons, ed. 2d. Prel. Remarks, p. 34.) A ſimilar obſervation has been made concerning animals hunted to death; as well as the human ſubject, when dying of ſome peculiarly malignant, and, as they are often called, putrid fevers. Here the exertions of the animal in one caſe, and the progreſs of the diſeaſe in the other, have been ſuppoſed to extinguiſh the vital principle almoſt entirely, previouſly to death.

Signs of Death.—Much diſpute has ariſen on this ſubject, in endeavouring to aſcertain ſome particular appearance, by which we may be certain that death has really taken place. The preceding account will ſufficiently convince the reader, that the ceſſation of reſpiration and the heart's action cannot be relied on for this purpoſe. Theſe ſigns become ſtill more fallacious on account of ſome extraordinary caſes of recovery from apparent death: although in common they may be regarded as a ſufficiently ſure criterion that the perſon is dead. In ſpeaking on this ſubject, Haller refers to the loſs of the irritable power of the heart; but this we have no means of aſcertaining. As ſingle ſymptoms, neither the ceſſation of the pulſe and breathing, nor coldneſs of the body, nor want of efflux of blood from a vein, nor inſenſibility to ſtimuli, nor relaxation of the ſphincters, and other muſcles, can be truſted to. But we may undoubtedly judge with great certainty from the combination of theſe various ſigns, and their continuation. Perhaps the rigid ſtate of the body, produced by the contraction of the muſcles, would be as ſure a ſign of death as any individual circumſtance. But this only laſts for a certain time.

Putrefaction is the ſpontaneous decompoſition which dead animal bodies undergo, and which is to be regarded as one of their moſt ſtriking peculiarities. This ſubject might indeed be conſidered as foreign to phyſiology, defined, as it has been, by ſome of the moderns, as the *ſcience of life*: but when we conſider that the changes occurring in the dead body, after the departure of the vital principle, throw light on that principle itſelf; the hiſtory of the body will ſtill belong to the phyſiologiſt, until its appearance can no longer recal any notion of its former ſtate, and every trace of organization has been completely effaced. The organs of the body, when abandoned by the vital powers, paſs under the dominion of thoſe phyſical laws, which govern all other inorganic matter. A new motion takes place in their interior, and their component elements manifeſt a tendency to ſeparate from each other, ſtronger in proportion to the complexity of their compoſition. We learn from chemiſtry that the diſpoſition of any body to change its mode of exiſtence is in a direct ratio with the multiplicity of its elements; and that an organized being will remain undecompoſed ſo much the longer, if its compoſition be ſimple, and its component parts few and not volatile in their nature.

A neceſſary condition for the occurrence of putrefaction is that the body ſhould be totally deprived of life; the vital powers are the moſt efficacious antiſeptic, and life itſelf is nothing more than a conſtant ſtruggle againſt phyſical and chemical agency. Life and putrefaction are therefore two abſolutely contradictory ideas; and when we hear various diſeaſes characterized by the epithet putrid, we muſt recollect that the changes denoted by this expreſſion are by no means ſuch as occur in putrefaction. The other circumſtances neceſſary to the decompoſition of the dead animal body are, 1ſt, a certain temperature, which ſhould be above 10° of Reaumur's ſcale. Cold carried to the freezing point is a complete preſervative from putrefaction, as long as the animal ſubſtance is expoſed to it. Hence the practice of keeping meat in ſnow in northern countries, and of tranſporting fiſh packed in ice to conſiderable diſtances. In general, the higher the temperature the more rapid is the putrefaction, provided the heat be not ſufficient to reduce the body to dryneſs; for then it is brought to the ſtate of ſome mummies. 2d, A certain degree of moiſture is alſo neceſſary, otherwiſe the body might be reduced to a mummy. 3d, The contact of air promotes the decompoſition by volatilizing the diſengaged elements, which riſe in the form of vapour. It is not, however, eſſential, as putrefaction will go on in vacuo.

The phenomena of putrefaction, reſulting from a ſeries of particular attractions, aſſume various modifications, according to the kind of ſubſtance which undergoes this change;

the medium, in which the proceſs tekes place; the different degrees of temperature and moiſture, under which it is carried on; and the ſtage of the proceſs itſelf. Theſe varieties may be included in the following general deſcription. A diſguſting cadaverous fœtor eſcapes from the part, which ſwells, ſoftens, and changes its colour ſucceſſively to various ſhades and mixtures of green, blue, and blackiſh brown. A dirty and very fœtid ſerous matter exudes; the texture of the part becomes relaxed, and its organization deſtroyed. We notice at the ſame time the eſcape of various gaſeous products, which are chiefly of an ammoniacal nature; and hence ariſes the pungent odour which is often very ſtrong in every ſtage of the proceſs. The other gaſes are the carbonic acid, which unites with the ammonia; hydrogen joined with phoſphorus, ſulphur and carbon, and azote. The odour gradually ſubſides; the reſiduary matter, conſiſting of oils and ſalts, becomes more conſiſtent, and of a deep colour, and laſtly forms a friable and rather deliqueſcent ſubſtance, particularly uſeful as a manure. The bones, being of a much more durable nature, retain their compoſition and figure, for a great length of time; yet if expoſed for a ſeries of ages to air and moiſture, their animal portion finally decays, and the earth crumbles away into a duſt. Thus at length every trace of our material exiſtence completely diſappears. "Putrefaction," ſays a modern phyſiologiſt, "when conſidered philoſophically, is the method employed by nature to bring back our organs, when deprived of life, to a more ſimple ſtate of exiſtence, that their elements may be employed in forming new combinations. (*Circulus eterni motus.* Beccher.) Nothing therefore can be more clearly proved than the metempſycoſis of matter; and we may reaſonably conclude, that this tenet, like moſt of the religious rites and fabulous conceptions of antiquity, is only a myſterious veil, dexterouſly interpoſed between the people and the knowledge of nature by the hand of philoſophy." Richeraud, Elemens de Phyſiologie, tom. ii. p. 491.

When dead animal matter is accumulated in a conſiderable maſs, ſo that its decompoſition is effected by the reciprocal action of its ingredients upon each other, or when it is placed in a running ſtream of water, the changes that enſue are very different from thoſe firſt detailed. All the ſoft parts are diminiſhed in ſize, and converted into a peculiar fatty matter, poſſeſſing much of the appearance and properties of ſpermaceti. This was obſerved firſt at the burial ground of the Innocents in Paris, where the poorer people were buried in vaſt numbers in large pits. Every part of the body undergoes this change. The ſubſtance in queſtion exhibits all the properties of ſoap, with an exceſs of fatty matter: and is ſtated by Fourcroy to conſiſt of adipous ſubſtance, combined with ammoniac. It is applicable to all thoſe manufactures in which tallow is uſed. See ADIPOCIRE.

DEATH, in *Pathology*. It has already been ſhewn, that, when death occurs before the natural changes, induced by old age, in the animal economy, have brought life to a concluſion, it happens in conſequence of ſome ſudden diſturbance of the ſyſtem, or of the more gradual operation of diſeaſe. In the former caſe, and in ſome of the more rapid inſtances of the latter, an interruption of the functions of the heart, the lungs, or the brain, has been ſhewn to be the immediate cauſe of death; *i. e.* death in ſuch caſes begins in one or the other of theſe vital organs. It remains, then, for us to point out the morbid changes, produced in thoſe organs, either by external violence, or the internal action of the conſtitution, by which their functions are obſtructed, and death is neceſſarily brought about.

Morbid Cauſes of Death.—Diſeaſes which directly impede the functions of the heart are, compared with thoſe that obſtruct the brain and the lungs in their action, but few, and of ſomewhat rare occurrence. Death is, however, thus produced occaſionally; as when an aneuryſm of the heart, or of the great veſſels attached to it, is ruptured; or when an abſceſs forms in the ſubſtance of the heart; or when the heart is wounded from external force. Several inſtances of a rupture of the heart itſelf, diſcovered on the diſſection of perſons who had died ſuddenly, are recorded by Morgagni, (De Sedib. et Cauſ. Mobor. Epiſt. xxvii.) in which the blood was in conſequence poured out, through the opening, into the ſac of the pericardium, and neceſſarily prevented the continuance of the motion of the heart. The ſubſtance of the heart was, in ſome of theſe caſes, corroded by ulceration; in others rendered thin by dilatation. An obſtruction to the heart's action is alſo occaſioned by a dropſy of the pericardium, when that inveſting membrane is diſtended with a watery effuſion from its veſſels. The heart is likewiſe impeded by the contrary condition of that membrane, namely, when it adheres firmly to the ſurface of the heart. See Cullen, Firſt Lines, § 1185.

It is the opinion of Morgagni, that the heart, being a muſcular ſubſtance, is, like other muſcles, liable to ſpaſm or convulſion, and that death is in fact ſometimes the reſult of a ſpaſm of the heart. He quotes the opinion of Herophilus, who taught that ſudden death, when it originated from no very evident cauſe, muſt be attributed to ſuch a ſpaſm; and he obſerves, that a convulſion of the heart is more than once mentioned by Hippocrates. See Epiſt. xxv. Art. 13. To this cauſe Bichât attributes the ſudden death, which is ſometimes induced by ſtrong emotions of the mind; as by exceſſive joy or deſpair, excited by the unexpected news of certain events, or the ſight of unexpected perſons or objects, &c. Although it may not be conceded to him, that theſe circumſtances influence the heart directly, and the brain only in a ſecondary way; yet it muſt be admitted, that the heart is affected by ſtrong mental emotions in a degree far beyond the other organs in general, and diſproportionately to the affection of the brain; and that its ceſſation, therefore, is the more immediate cauſe of the death which enſues. The death, in this caſe, is a permanent ſyncope, and differs from a common *fainting fit* only in its duration. See Bichât, loc. cit. p. 231.

As the function of reſpiration is two-fold, conſiſting partly of mechanical, and partly of chemical operations; ſo death may begin in the lungs, when either the one or the other of theſe actions is interrupted, by external accident, or by diſeaſe. The mechanical act of reſpiration is arreſted partially or completely by the diſlocation of the ſpine of the neck, and the conſequent compreſſion of the ſpinal marrow, in that part: it is partially impeded if the diſlocation take place below the origin of the phrenic nerves; becauſe then the intercoſtal muſcles alone are paralyzed, and breathing goes on to a certain degree by means of the diaphragm: it is completely arreſted, if the compreſſion is above that point of the ſpinal marrow, from which the phrenic nerves originate; becauſe the diaphragm is then paralyzed too. The mechaniſm of reſpiration may be alſo obſtructed by any large wound or aperture into the thorax, through which air may be freely admitted; for, in ſuch a caſe, the external air will ruſh in, on the expanſion of the cheſt, and, preſſing on the ſurface of the lungs, will counterbalance the air in their cells, and thus prevent their alternate diſtenſion and evacuation, by the motion of the ribs and the diaphragm.

Some diſeaſes terminate in death, in conſequence of mechanically impeding the admiſſion of air into the lungs. The hydrothorax, or dropſy of the cheſt, which conſiſts of an

an effuſion of a watery fluid into the cavity of the thorax between the lungs and the ribs, neceſſarily retains the lungs in a compreſſed and contracted ſtate; it is the more ſpeedily fatal, if combined with the dropſy of the belly, and of the pericardium; the former of which, by preſſing the diaphragm upwards, cauſes an additional contraction of the cavity of the cheſt; the latter, by occupying a larger ſpace in that cavity. An oppoſite morbid condition has ſometimes, though rarely, produced death, by a mechanical impediment to reſpiration; namely, an univerſal adheſion of the lungs to the ribs and diaphragm, which altogether prevented the play of the lungs, and the proper expanſion of the cheſt. A caſe of this deſcription is recorded by Dr. Marcet, in the Edinburgh Medical and Surgical Journal, vol. i. p. 412. It is probable that a convulſive ſtate of the muſcles of reſpiration occaſionally produces a fatal interruption to the mechanical act of reſpiration in ſome convulſive diſeaſes. See Lanciſi de ſubitaneis mortibus, lib. i. cap. 9.

But the more common cauſes of a fatal interrupton of the function of the lungs, conſiſt of impediments to the chemical changes in the blood, which are neceſſary to the ſupport of life; that is, of impediments to the acceſs of pure air, or air containing oxygen. Thus life is ſpeedily deſtroyed by hanging or drowning; the preſſure of the rope obliterating the paſſage of the wind-pipe in the former caſe, and water preventing the acceſs of air in the latter. See STRANGULATION and DROWNING. In the ſame way the introduction of any foreign ſubſtance, as particles of food, &c. into the glottis, may occaſion a fatal impediment to breathing, and the perſon is ſaid to be choked. Among the caſual cauſes of ſuffocation, the breathing of the deleterious airs generated in mines, at the bottom of wells, or in cloſe rooms by the burning of charcoal fires, the fermentation of liquors, or the reſpiration of a crowded people, are the principal. Of the firſt we have inſtances in the *choke-damp*, as it is called by miners, conſiſting of carbonic acid, and which ſpeedily kills thoſe who are unfortunately immerſed in it; and of the laſt, the fatal impriſonment in the black-hole at Calcutta affords a memorable example.

Many diſeaſes terminate fatally by impeding the chemical changes of the blood in its paſſage through the lungs. Some operate by obſtructing the entrance of air through the paſſages, ſuch as croup, in which the wind-pipe is ſtuffed up by a ſecretion of lymph from its internal ſurface, which produces ſuffocation; and ſpaſmodic aſthma, in which, during the paroxyſm, the paſſages are ſpaſmodically contracted. But a more ſudden and complete interruption to the communication of air to the circulating fluids, is occaſioned by the burſting of a large blood-veſſel within the lungs, and of courſe by the ſudden filling up of the air-cells and paſſages with blood. A ſimilar reſult follows the burſting of a large abſceſs, or vomica, in the lungs, as ſometimes occurs in pulmonary conſumption, or after acute inflammation of thoſe organs; it follows likewiſe from the rapid effuſion of lymph into the cells, in the latter diſeaſe, and more gradually from the redundant ſecretion of mucus in the peripneumonia notha, and in the catarrh of old and debilitated perſons. Occaſionally, a dropſical effuſion into the ſubſtance of the lungs, or anaſarca pulmonum, arreſts the proceſs of reſpiration in a ſimilar manner. So numerous are the morbid changes in the organs of breathing, by which life is annihilated.

Bichât is diſpoſed indeed to affirm, that in the majority of ſlow diſeaſes of every kind, death begins in the lungs. But, although a difficult and laborious reſpiration is one of the moſt obvious ſymptoms of departing life, yet an accurate obſerver will remark, in many caſes, a previous failure in the functions of the brain, or of the heart and arterial ſyſtem; and this affection of the lungs muſt be conſidered, under ſuch circumſtances, as ſecondary, in this circle of aſſociated and mutually dependent functions.

The morbid affections which terminate life, by impeding the operations of the common ſenſorium on the organs of the body, are very numerous, as will be obvious from a ſlight peruſal of the works of Morgagni and other morbid anatomiſts. The different parts of the brain, and its inveſting membranes, have been found thickened, indurated, inflamed, converted into bone, connected by adheſion, compreſſed by effuſions of blood, or of its ſeparate parts by diſtended veſſels, by abſceſſes, tumours, hydatids, and excreſcences from the cranium. And beſide theſe palpable and evident cauſes of the death of the brain, the ſame conſequence has reſulted from concuſſion, as it is termed, and even from ſlight blows, where no perceptible alteration had been produced. In theſe various morbid affections of the encephalon, the ſymptoms, which precede death, are thoſe of apoplexy, palſy, coma, fatuity, epilepſy, frenzy, fever, hemicrania, &c.; or, in other words, theſe diſeaſes deſtroy life by compreſſion, or irritation of the brain in ſome of the modes juſt ſtated.

The functions of the brain may be deſtroyed by ſeveral vegetable and animal poiſons; the former, when taken into the ſtomach, affecting the brain through the medium of the nerves of that organ; the latter, being inſtilled into a wound, ſometimes deranging the ſenſorium by means of the circulation directly, as the poiſon of the rattle-ſnake and the viper; and ſometimes perhaps indirectly, as the poiſon from a rabid animal, by the abſorbents. Between the ſtomach and the brain, a cloſe connection through the nervous ſyſtem exiſts, whence perhaps not only an overdoſe of opium, henbane, or ſpirituous liquors, &c., but a blow on the epigaſtric region, or the *wind* of a cannon ball, as has been affirmed, have often produced inſtantaneous death.

The ſenſorial power, however, is not only deſtroyed by the mechanical changes of ſtructure in the brain above enumerated, and by the influence of narcotic ſubſtances, and other cauſes, through the medium of the nerves; but many other circumſtances conduce to exhauſt it, and thus to terminate life. It is a general fact in the animal economy, however whimſically Brown and Darwin may have theorized upon it, that the ſenſorial power, (or excitability, or nervous energy, or by what other term we may chuſe to deſignate it,) is diminiſhed and exhauſted by long continued or exceſſive action, as well as by the abſtraction of thoſe matters neceſſary to the ſupport of the body. Thus death is occaſioned by the exceſſive vaſcular action in fevers, which exhauſts the nervous power when no morbid ſtructure of any of the three vital organs exiſts; the ſupport of the conſtitution by digeſtion and nutrition being at the ſame time withdrawn. Thus alſo the exceſſive muſcular action in convulſions ſometimes exhauſts life; and even long continued violent pain, or thoſe leſs intolerable feelings which come under the denomination of irritation, not unfrequently wear down the vital powers, as in the confluent ſmall-pox, when the ſkin is covered with puſtules. In chronic diſeaſes accompanied by hectic fever, the conſtitution is thus worn out, perhaps in a great meaſure by the defect of nutrition, in conſequence of the loſs of the digeſtive power, which every ſtate of fever occaſions, as well as by the great exhauſtion of the febrile action, and of the profuſe ſweats.

By the abſtraction of nouriſhment, produced in various ways, life muſt be obviouſly exhauſted, as by long faſting; or by an obſtruction to the digeſtive proceſs, or to the paſſage of the food into the inteſtines (in ſchirrous pylorus), or through the lacteal into the blood (in meſenteric diſeaſes). Or it may be exhauſted by great diſcharges of the blood itſelf,

in great hæmorrhages; or by profuſe ſecretions from the blood, as of the urine in diabetes; of ſweat in chronic diſeaſes; of the inteſtinal liquids, in diarrhœa, and dyſentery; of the fluids of the uterus and vagina, in menorrhagia, fluor albus, &c. The abſtraction of the neceſſary ſtimulus of heat, or, in common language, the application of cold, is frequently fatal to the powers of life. (See COLD.) So true is the obſervation of Seneca, "naſcimus uno modo, multis morimur."

The conſideration of the phyſical proceſs of death is generally ſhunned, although on a near view it loſes much of its horror. Thoſe who have frequently witneſſed it allow that it is not generally a painful proceſs. In ſome delicate and irritable perſons, a kind of ſtruggle is indeed ſometimes excited, when reſpiration becomes very difficult; but more frequently the dying obviouſly ſuffer nothing, and expreſs no uneaſineſs. Our obſervation accords with that of an elegant and intelligent writer, who obſerves, "in thoſe who die of chronic dieaſes, the gradation is ſlow and diſtinct. Conſumptive patients are ſometimes in a dying ſtate during ſeveral days; they appear at ſuch times to ſuffer little, but to languiſh for complete diſſolution; nay, I have known them expreſs great uneaſineſs, when they have been re-called from the commencement of inſenſibility, by the cries of their friends, or the efforts of the attendants to produce pain. In obſerving perſons in this ſituation, I have always been impreſſed with an idea, that the approach of actual death produces a ſenſation ſimilar to that of falling aſleep. The diſturbance of reſpiration is the only apparent ſource of uneaſineſs to the dying; and ſenſibility ſeems to be impaired, in exact proportion to the decreaſe of that function. Beſides, both the impreſſions of preſent objects, and thoſe recalled by memory, are influenced by the extreme debility of the patient, whoſe wiſh is for abſolute reſt. I could never ſee the cloſe of life, under theſe circumſtances, without recollecting thoſe beautiful lines of Spenſer:

"Sleep after toil, port after ſtormy ſeas,
Eaſe after war, death after life, doth greatly pleaſe."
Ferriar. Med. Hiſt. b. 1.

We have obſerved in more inſtances than one, a perſon juſt ſinking into the ſleep of death, expreſſing in a languid voice, but with every ſign of perfect complacency, a ſenſe of his dying ſtate. In ſudden deaths nothing can be ſaid on this point, as little time intervenes between the commencement of death and abſolute inſenſibility; and in acute diſeaſes inſenſibility often precedes death for ſome conſiderable time.

It is the taſk of humanity, however, to mitigate the ſufferings of the dying, and, where nature has produced none, to take care that the officiouſneſs of art ſhould not inflict them. The length of the interval between inſenſibility and the abſolute ceſſation of exiſtence, has given riſe to a multitude of ſuperſtitious notions and miſchievous practices among the vulgar. Indeed ſome of theſe notions are of conſiderable antiquity; but it does not appear that, in thoſe early ages, the attendants preſumed to accelerate the death of the ſufferer. In the 16th and 17th centuries, however, it was very common to ſtrip the dying, to drag them out of bed, and place them on mattraſſes of ſtraw or hair, in the middle of the room. Religious habits, aſhes, and relics, were then thrown upon them, for the conſolation of thoſe,

——"who, to be ſure of Paradiſe,
Dying put on the weeds of Dominic,
Or in Franciſcan thought to paſs diſguis'd."

The effects of theſe impreſſions ſtill remain. It is a prevalent notion among nurſes and ſervants, that a patient, whoſe death is lingering, cannot quit life while he lies on a common bed, and that it is neceſſary to drag the bed away, and to place him on the mattraſs. This piece of cruelty is often practiſed, when the attendants are left to themſelves. A ſtill more hazardous practice has been very prevalent in France and Germany, and, it is to be feared, is not altogether unknown in this country. When the patient is ſuppoſed by the nurſes to be nearly in a dying ſtate, they withdraw the pillows and bolſter from beneath his head, ſometimes with ſuch violence as to throw back the head, and to add greatly to the difficulty of reſpiration, if not to produce actual ſuffocation. Another improper practice is the precipitation with which the attendants *lay out* the body, immediately after death has taken place. They have often been known to ſtrip the body in very cold ſtormy weather, wrap it in cold linen, throw a ſingle ſheet over it, and open the doors and windows of the apartment, in little more than half an hour after a patient had died ſuddenly.

It is too certain that the helpleſs patient feels all theſe cruelties, after he has become unable to expreſs his ſenſations diſtinctly. The teſtimony of perſons who have recovered from apparent death, leaves no doubt on this head. See a diſtreſſing caſe of this ſort under the article CATALEPSY. But the means of prevention of ſuch ſuffering in the dying are eaſy.

"Diſturb him not—let him paſs peaceably."
Shakeſpeare.

"When the toſſing of the arms, which I have deſcribed," ſays Dr. Ferriar, "the rattling noiſe in reſpiration, and difficulty of ſwallowing have come on, all unneceſſary noiſe and buſtle about the dying perſon ſhould be prohibited. The bed-curtains ſhould be drawn nearly cloſe, and unleſs the patient ſhould place himſelf in a poſture evidently uneaſy, he ſhould be left undiſturbed. Exclamations of grief, and the crowding of the family round the bed, only ſerve to harraſs him. The common practice of plying him with liquors of different kinds, and of forcing them into his mouth, when he cannot ſwallow, ſhould be totally abſtained from.

"When he no longer breathes, one perſon only ſhould remain in the room, who ſhould take care that no alteration be made in the ſtate of the bed. Every thing ſhould be conducted as if he were in a tranſitory ſleep. If the weather be hot, the windows of the room may be opened, and the bed curtains undrawn in the courſe of two or three hours. In winter, it will be ſufficient to withdraw the curtains within that time.

"There can be no juſt reaſon for the haſte, with which it is uſual to lay out the body. Several hours may be very properly ſuffered to elapſe before this is done; for the joints do not commonly become rigid for a conſiderable time. At the end of that period, the body will be completely cold, and all remains of ſenſibility will have been extinguiſhed." Ferriar on the Treatment of the Dying, loc. cit. vol. iii.

Theſe obſervations relate ſolely to the propriety of ſmoothing the bed of death. For, happily, the uſage of keeping the body unburied during ſeveral days is ſo firmly eſtabliſhed in this country, that it is unneceſſary to ſpeculate on the poſſibility of abuſes, in regard to premature interment. In France a very blameable, even criminal, degree of haſte ſeems to have been uſed in this reſpect, at the time when Bruhier wrote. For he obſerves, that the rituals, which were moſt cautiouſly drawn up, only enjoined the delay of interment for twenty-four hours after death, and that others directed it to be performed within half of that period. See his treatiſe de l'Incertitude des Signes de la Mort. The

ſlighteſt

ſlighteſt appearance of beginning putrefaction affords ſufficient ſecurity againſt any reviſitings of life; and marks of this nature are almoſt always viſible, before the date of interment obſerved in this country.

Death, in *Theology*. The nature and extent of death, in its connection with the fall of our firſt parents, and denounced as a penalty in conſequence of their tranſgreſſion, have afforded occaſion for a difference of opinion among divines and biblical critics. It has been generally ſuppoſed that the privilege of continued life was connected by a divine conſtitution with the innocence or ſinleſs obedience of the firſt progenitors of our race; and that the providence of God would preſerve and prolong their exiſtence, notwithſtanding thoſe natural decays, and that tendency to diſſolution, to which their natural frame muſt neceſſarily have been ſubject. The tree of life, to which they had acceſs, was either a pledge of permanent being and happineſs, or the appointed means of ſecuring them; and the prohibition to abſtain from the fruit of the tree of the knowledge of good and evil, was merely intended to prevent their forfeiture of happineſs, and the loſs of life, on which their happineſs depended. Joſephus, and ſome of the ancients, abſurdly imagined, that this latter tree was ſo called, becauſe there was ſomething in its fruit that by its own nature conveyed knowledge or wiſdom; but this is the effort of ſtudy and inquiry, and not of eating or drinking, at leaſt in any other way than by the experience it gives, and the effects it produces. In this ſenſe eating indeed conveys a great deal of knowledge both of good and evil, inaſmuch as the eating of noxious and poiſonous food, or proper and wholeſome food in an intemperate manner, will give a very ſenſible knowledge of good, *viz.* of the value of the eaſe and health that are loſt, by the evil that it introduces. This, if we underſtand the hiſtory in a literal ſenſe, (ſee Fall,) may be the true reaſon of the name of this tree, that of the knowledge of good and evil. Thus, the tree of life, and the tree of the knowledge of good and evil, ſeem to ſtand in oppoſition to each other, and to be of directly contrary qualities. The tree of life was certainly of an healing, reſtorative nature, and would have prolonged life to the longeſt period of duration. (See Gen. iii. 22, and Rev. xxii. 2, in which latter paſſage this tree is alluded to.) In oppoſition to this was the tree of the knowledge of good and evil, the fruit of which, however pleaſing to the ſight or grateful to the taſte, was of a pernicious and deadly quality, and tended to introduce thoſe diſorders in the body, which would eventually, and in their own nature, lead to and iſſue in death. The prohibition of the fruit of this tree was juſtly made by the great Creator and Lord of man, not merely for the exerciſe of his ſovereign authority and power, but as an inſtance of his goodneſs to, and care of, the new-formed creature he had placed in Eden, and in order to prevent him, through want of experience, from deſtroying himſelf. The exception of this tree may be conſidered partly as a friendly caution, and principally as an expreſs prohibition, carrying in it a poſitive injunction wholly to abſtain from its fruit; and in this ſenſe our firſt parents underſtood it. (Gen. iii. 1. 3.) The penalty threatened againſt the violation of this prohibition is expreſſed in theſe words, "thou ſhalt ſurely die," or "in dying thou ſhalt die:" a form of ſpeaking which commonly has an emphatical meaning; ſometimes denoting the abſolute certainty of any thing, and having in it the nature of a ſtrong affirmation; and ſometimes ſignifying what is extraordinary in its kind, and the continuation of the thing ſpoken of, and the gradual accompliſhment of it. "In the day thou eateſt thereof, in dying thou ſhalt die," *i. e.* inſtantly become incurably mortal, and tending all thy days to diſſolution and death.

Death, threatened as a penalty in conſequence of ſin, and contraſted againſt the preſent life, bleſt with all the comforts and privileges of it, and regarded as a deſirable privilege, muſt be a ſubſtantial puniſhment, and an awful inſtance of the divine diſpleaſure againſt ſin: and as the recovery to life is as far beyond the reach of the power of man, as the firſt grant of it was, this threatening, "thou ſhalt ſurely die," was not only a condemnation to certain death, but as to any thing man could do to prevent it, to perpetual and eternal death, and the entire and final loſs of life and happineſs. It has been abſurdly objected by ſome to the truth of the ſcripture hiſtory, that the ſentence of death was not executed immediately, or on the day of the tranſgreſſion. But the expreſſion, "in dying thou ſhalt die," properly interpreted, furniſhes no ground for this objection: for it ſignifies, thou ſhalt certainly, but gradually die, inſtantly become liable to death, and be perpetually tending to it, without any poſſibility of a final reprieve, or knowing when the ſentence ſhall be executed in its full weight and extent. Some perſons have alſo objected to the equity of this ſentence, or of the connection between the eating of the forbidden fruit and the puniſhment of death that attended it. Dr. Chandler, in conſidering this objection, (Sermons, vol. iv. p. 17, &c.) obſerves, that as eating the forbidden fruit and the puniſhment of death aroſe out of the nature of things, and had the connection of cauſe and effect, nothing more need be ſaid in vindication of it than for any other natural connection of this kind whatſoever. Beſides, no creature has a right to life long, or upon any other terms than the Creator pleaſes. Again, the nature of Adam's crime, when conſidered in its proper view, will appear to be extraordinary, and his guilt attended with peculiar and heinous aggravations, and on ſome accounts with unqueſtionably much greater than ever was, or ever could be committed by any of his poſterity. His tranſgreſſion was folly in its nature, and a high immorality of a moſt enormous kind, and a ſin immediately againſt God, with the worſt aggravations attending it. Moreover, it involved their poſterity to the end of time, through all ages and nations, in the conſequences of it, and ſubjected them to two of the greateſt evils, ſin and death. Farther, notwithſtanding the objections that may be urged againſt the credibility of this part of the ſcripture hiſtory, from the extraordinary conduct of God, and the ſeeming diſproportion between the offence and the puniſhment threatened to and inflicted upon it, yet there is in reality nothing extraordinary in it; nothing but what occurs in the common government of God, and what is allowed reaſonable and fit, upon the principles of natural as well as revealed religion. The ſacred hiſtory informs us, that our firſt parents, by eating the forbidden fruit, *i. e.* by indulging their appetites contrary to their knowledge and conviction of duty, and by ſuffering themſelves to be led away by the force and influence of temptation to tranſgreſs the law of God, by forfeiting their innocence, and ſuffering inclination to ſubdue the dictates of conſcience, forfeited the favour of God, and ſubjected themſelves to affliction, miſery, and death. And as far as this aroſe from the natural connection of things, does not the ſame connection ſtill hold? Do not the ſame criminal indulgences produce the ſame effects? Moreover, one ſevere and grievous part of the puniſhment of our firſt parents, their being prohibited acceſs to the tree of life, and being irrecoverably given up to the condemnation of death, was, if the matter be rightly conſidered, an act of

real compaſſion and goodneſs on the part of God. A ſcheme of recovery was immediately commenced upon their tranſgreſſion, and they had evident intimations of mercy as ſoon as their ſentence of puniſhment was announced.

Several other learned writers underſtand by the penalty of death denounced againſt the tranſgreſſion of our firſt parents, not merely the ſeparation of the ſoul from the body, or its removal from one ſtate of conſciouſneſs to the other, but the utter extinction of the human being, or death eternal, without hopes of a revival or reſurrection. To this purpoſe Dr. Taylor obſerves, (Scripture Divinity, p. 102.) that every tranſgreſſor, the moment he is ſuch, is dead in law: and, for any thing in law, he muſt continue ſo as long as it is true, that he has violated the law, that is, for evermore. The language of the law to every one that tranſgreſſes it, and for every breach and tranſgreſſion, is this, "Thou ſhalt die." And this, he ſays, is the force of the expreſſion, מות תמות, "in dying thou ſhalt die," in the law given to Adam. It does not ſpeak of the certainty of the event, as if he ſhould certainly die the day he tranſgreſſed; for the event ſhews the contrary; nor that he ſhould become mortal from a change in his conſtitution, which is a random conjecture, without any foundation in the nature of his conſtitution, which was created mortal, or in the force of the words. For the phraſe מות תמות, is an Hebraiſm, importing that a thing is, or is done, thoroughly, totally, in the moſt perfect manner, or the moſt intenſe degree, and is to be interpreted according to the nature of the ſubject. (See Gen. ii. 16. xxxvii. 33. Exod. xxi. 19.) Thus the force of the words, "in dying thou ſhalt die," is this, thou ſhalt thoroughly, utterly, totally die, or die for ever, without coming to life again. Thou haſt juſtly forfeited thy life and being, and ſhalt ſuffer a total and eternal extinction of it. Athanaſius (De Incarn. Verbi) thinks, that the doubling of the expreſſion in the above cited ſentence, denotes, that "he ſhould not only die, but remain in the corruption of death;" as we ſhould all have done, if the ſecond Adam had not obtained for us a happy reſurrection. This ſurely, ſays biſhop Law (Conſiderations on the Theory of Religion, p. 348, ed. 7.), and nothing leſs, muſt be implied in that moſt ſolemn ſentence: nor can we well conceive the unhappy ſubjects of it to have been at that time ſo very ingenious as to explain it away, by diſtinguiſhing upon the ſeveral component parts of their conſtitution; and concluding, that by death no more was intended, than only a ſeparation of theſe parts, while the principal of them was ſtill living in ſome different manner: or that it was a continuation of their conſciouſneſs, and real exiſtence, though in ſome other place. This, he ſays, was the philoſophy of after ages. Dr. Jortin alſo once held a ſimilar opinion (Serm. vol. vii. p. 283), though he afterwards adopted the contrary doctrine. If death, ſays the learned prelate (ubi ſupra), be a return to duſt, then nothing but a reviving, or a reſuſcitation from that duſt, can be the reverſing of it, or a proper recovery from it; and accordingly, as he conceives, to this, and this alone, St. Paul confines the contraſt, he has drawn at large, between the firſt and ſecond Adam: "Since by man came death, by man came alſo the reſurrection from the dead; and as in Adam all die, even ſo in Chriſt ſhall all be made alive;" which words directly affirm, ſays Taylor (Doctr. of Orig. Sin, p. 24.), "that a reſurrection, or body made alive again, is granted, aſſured, and executed by and in Chriſt alone," and evidently ſuppoſe, that the dead are not made alive till the reſurrection; and that if a reſurrection had not been provided, we ſhould never after death have been made alive. Biſhop Sherlock purſues the ſame kind of reaſoning in ſimilar language. (Diſc. ii. p. 76. 300. Diſc. vi. p. 209. Uſe and Intent of Prophecy, p. 69, &c. ed. 2.) The ſame notion of death, and of an unconſcious ſtate between death and the reſurrection, is adopted by Dr. Prieſtley, in conformity to his ideas of the homogeneity of man, and inculcated in his Inſtitutes and various other writings.

An ingenious writer, and an excellent Biblical critic, however, is of a very different opinion; and he deduces, from the antiquity of the worſhip of dead men, an explication of the term death in the threatening denounced againſt Adam, ſimilar to that with which we have introduced this ſubject, conformable to his idea of the ſoul, as a ſubſtance or principle diſtinct from matter and the body, and conſiſtent with his belief of a ſeparate ſtate. For an abſtract of his reaſoning on this intereſting ſubject, ſee SLEEP *of the Soul*. See alſo SOUL and RESURRECTION.

Death, in its original and moſt proper and natural ſenſe, ſignifies, as we have ſhewn, the loſs of life, and together with it, of all its bleſſings and comforts. This is the common, if not the univerſal, ſenſe of the word in the writings of Moſes; and in the ſanction of a law, it is reaſonable to ſuppoſe the word is uſed in its moſt natural and proper ſenſe. Death, in Scripture, is uſed ſometimes for the loſs of privileges, benefits, and comforts, even when life remains. In this ſenſe it ſignifies the ſoul's loſs of the image of God, of holineſs, and peace; this is called "ſpiritual death." Thus the Epheſians are ſaid to be "dead in treſpaſſes and ſins." (Epheſ. ii. 1.) Sometimes death ſignifies the loſs of bleſſings in the world to come, together with poſitive ſufferings both in ſoul and body. Thus, in Rom. viii. 13. "if ye live after the fleſh, ye ſhall die." (See John vi. 50.) In Rev. xxi. 18. this is called "the ſecond death:" and ſome have ſuppoſed, that it denotes the final deſtruction of the incorrigibly wicked, whom neither milder nor more ſevere diſcipline can reform, and render capable of the happineſs connected with piety and virtue.

DEATH, *Mors*, in *Mythology*, a divinity, which, according to the theogony of Heſiod, was the offſpring of Night, and whoſe brother was Sleep. (See SLEEP.) The Greek poets, as well as the Latins, and Virgil (Æn. l. 2.) among others, reckon death among their gods. It is not known what worſhip they paid her; but it is certain that the Lacedæmonians honoured her as a divinity, and had, as Pauſanias informs us, (in Lacon.) one of her ſtatues near that of her brother Sleep. Mors, or Death, was the moſt powerful miniſter of the infernal deities, and brings all mortals down to the river Acheron. It is ſaid that her mother Nox, or Night, beſtowed peculiar care on her education, and that ſhe had a great affection for her brother Somnus, or Sleep. Among the Elæans there was a temple, with the ſtatue of a woman holding in either hand a ſleeping boy, with their legs diſtorted; that in her right was white, to ſignify Sleep; that in her left was black, to repreſent Death; whilſt the female that foſtered them was Night. No ſacrifices, no temples, no ceremonies, no prieſts, were appointed for death, becauſe ſhe was looked upon as an inexorable deity, whom no prayers could move, nor ſacrifices pacify. The figures of Mors, or Death, are, as Mr Spence ſays, very uncommon, as were thoſe of the evil and hurtful beings in general; they were excluded from all medals; on ſeals and rings they were probably conſidered as bad omens, and were perhaps never uſed. Among the few figures of Mors met with by this ingenious writer, that in the Florentine gallery was the moſt remarkable: it is a little figure, in braſs, of a ſkeleton, ſitting on

the ground, and reſting one of his hands on a long urn. The figure of Mors might have been very common in ancient paintings, becauſe ſhe is frequently mentioned by the Roman poets, who diſtinguiſhed her from Lethum. The latter was that general cauſe or ſource of mortality, which they ſuppoſed to have its proper reſidence in hell, and Mors or Mortes, for they had ſeveral of them, they regarded as the immediate cauſe of each particular inſtance of mortality that occured on our earth. The face of Mors ſeems in their repreſentation of it, to have been of a pale, wan, dead colour. The poets deſcribe her, as ravenous, treacherous, and furious. They deſcribe her as roving about open-mouthed, and as ready to ſwallow up all that came in her way; they ſeem to give her black robes and dark wings, and repreſent her often as of an enormous ſize. Statius gives her arms and a ſword, exhibiting her like a deſtroying angel, where he is deſcribing a peſtilence. The ancient poets ſometimes repreſent her as coming to the doors of mortals, and thundering at them, to demand the debts they owe her: ſometimes approaching to their bedſides, and leaning over them: and at other times, purſuing her prey, or hovering in the air, and ready to ſtoop upon it. She is alſo repreſented as purſuing men with a net, catching them, and dragging them to their tombs. Of all the pictures of this deity exhibited by Statius, the moſt particular is that which repreſents her as ſtanding by the bed-ſide of a youth juſt in the flower of his age, accompanied by Envy and Vengeance. Theſe horrid deities manifeſt great friendſhip to one another in the execution of their cruel offices, and Vengeance, in particular, after having embraced the goddeſs of death, ſeems, according to his account, to take the fatal net out of her hand, and to perform her office for her.

Death, *Appeal of*, in *Law*. See Appeal *of death*.

Death, *Civil*. The law diſtinguiſhes between natural and civil death: the former is the actual termination of life; the latter, when a perſon is not actually dead, but adjudged ſo by law. Thus, by ſtat. 19. Char. II. c. 6., if a perſon for whoſe life an eſtate is granted remain beyond ſea, or is otherwiſe abſent ſeven years, and no proof be made of his being alive, or becomes a profeſſed monk, he ſhall be accounted naturally dead. However, the latter diſability, ſince the Reformation, is held to be aboliſhed. But if the party beyond ſea be afterwards proved living at the time of eviction of any perſon, then the tenant, &c. may re-enter and recover the profits. By ſtat. 6. Ann. 1. 18., perſons in reverſion or remainder, after the death of another, upon affidavit that they have cauſe to believe ſuch other dead, may move the lord chancellor to order the perſon to be produced; and if he be not produced, he ſhall be taken as dead; and thoſe claiming may enter. See Civil *Death*.

Death-*Watch*, in *Zoology*, the Engliſh name of the *pediculus* of old wood, a ſpecies of the *termes*, belonging to the order of aptera and claſs of inſects in the Linnæan ſyſtem. (See Termes.) It is nearly of the ſize of the common louſe; and the noiſe reſembling the beating of a watch is made by the male or female, when wooing each other This ticking noiſe the populace have long taken for a preſage of death, in the family where it is heard: whence it is alſo called pediculus fatidicus, mortiſaga, pulſatorius, &c.

There are two kinds of *death-watches*: of the firſt we have a good account in the Philoſophical Tranſactions, by Mr. Allen. It is a ſmall beetle, five ſixteenths of an inch long, of a dark brown colour, ſpotted; having pellucid wings under the vaginæ, a large cap, or helmet, on the head, and two antennæ proceeding from beneath the eyes. The part with which it beats, he obſerved, was the extreme edge of the face, which he chooſes to call the upper lip; the mouth being protracted by this bony part, and lying underneath, out of view.

This account is confirmed by Mr. Derham, with this difference, that, inſtead of ticking with the upper lip, he obſerved the inſect to draw back its mouth, and beat with its forehead. That author had two death-watches, a male and female, which he kept alive in a box, ſeveral months; and could bring one of them to beat whenever he pleaſed, by imitating its beating: and by this ticking noiſe he could frequently invite the male to get up upon the other, in the way of coition. When the male found he got up in vain, he would get off again, beat very eagerly, and then up again: whence the ingenious author concludes thoſe pulſations to be the way whereby thoſe inſects woo one another, and find out, and invite each other to copulation.

The ſecond kind of death-watch is an inſect in appearance quite different from the firſt. The former only beats ſeven or eight ſtrokes at a time, and quicker: the latter will beat ſome hours together, without intermiſſion; and his ſtrokes are more leiſurely, and like the beat of a watch. This latter is a ſmall greyiſh inſect, much like a louſe when viewed with the naked eye. The ticking, as in the other, is a wooing act.

This inſect is at firſt a minute white egg, much ſmaller than the nits of lice; though the inſect is near as big as a louſe. In March it is hatched, and creeps about with its ſhell on. When it firſt leaves its ſhell, it is even ſmaller than its egg; though that be ſcarce diſcernible without a microſcope. In this ſtate it is ſomewhat like the mites in cheeſe: from this ſmall ſtate they grow gradually to their mature or perfect ſize: when they become like the old one, they at firſt run about much more ſwiftly than before. Philoſoph. Tranſ. abr. vol. v. p. 26, &c.

The minute inſect, which has been long known under the name of the death-watch, has been thus noticed by Linnæus: "frequens in domibus, inviſum veſtibus, herbariis, inſtitorum muſeis. Fœmina horologii inſtar pulſatoria feſtucis, (Syſt. Nat. p. 1015, No. 2.) Geoffroy, however, ſays, he is confident that it is not from this inſect, but from the "dermes domeſticus," (Syſt. Nat. p. 563, No. 12.) which makes the circular holes in furniture, that the ticking noiſe proceeds. (Hiſt. des Inſectes, tom. i. p. 3. and tom. ii. p. 602.) Neither of theſe is larger than the pediculus humanus. Dr. Shaw aſſures us, that the inſect properly called the death-watch is a coleopterous inſect of the genus "ptinus." (Syſt. Nat. p. 565.) He ſays it is chiefly in the advanced ſtate of the ſpring that this alarming little inſect commences its ſound; the prevailing number of diſtinct ſtrokes is from 7 to 9 or 11; theſe are given in pretty quick ſucceſſion, and are repeated at uncertain intervals; and in old houſes, where the inſects are numerous, they may be heard almoſt every hour of the day, eſpecially if the weather be warm. The ſound exactly reſembles that which may be made by beating moderately hard with the nail on a table. The inſect is about a quarter of an inch in length. This ingenious and accurate naturaliſt has diſtinguiſhed the inſect by the name of "ptinus fatidicus," the beating ptinus, and ſuppoſes it to be the ſame with the "dermeſtes teſſelatus" of Fabricius, and the "ptinus pulſator" of Gmelin. He alſo cautions us not to confound this inſect, which is the real death-watch of the vulgar, emphatically ſo called, with another inſect, which makes a ſound like the ticking of a watch, and which continues its ſound for a long time without intermiſſion: it belongs to a totally different tribe from the death-watch, and is the "termes pulſatorium" of Linnæus. (Nat. Miſc. vol. iii.) Whichſoever of the inſects above deſcribed is the real death-watch, it is well known

that

that for a ſeries of years the dread of it has excited very uneaſy ſenſations in the minds of the weak and ſuperſtitious; an unhappy prejudice which exiſts even to the preſent day, and cannot be totally eradicated by all the powers of reaſon and argument. Sir Thomas Brown (Pſeudo-doxia Epidemica, b. ii. c. 7.) long ago obſerved, "he that could extinguiſh the terrifying apprehenſions hereof, might prevent the paſſions of the heart, and many cold ſweats in grandmothers and nurſes." With the feelings of theſe perſons, a well-known ſatiriſt ſports in the following lines:

——— "a wood-worm
That lies in old wood, like a hare in her form:
With teeth or with claws it will bite or will ſcratch,
And chamber-maids chriſten this worm a DEATH-WATCH:
Becauſe like a watch, it always cries click,
Then woe be to thoſe in the houſe, who are ſick,
For ſure as a gun, they will give up the ghoſt,
If the maggot cries click, when it ſcratches the poſt."

DEATH'S *Head*, or *Human Skull*, in *Heraldry*, is often borne in arms, and thus generally blazoned. An order of knighthood under this appellation was inſtituted in Sileſia, by Silvius Nimrod, duke of Wurtemberg, in 1652, for men and women; and revived in the year 1709, by Louiſa Elizabeth, widow of Philip, duke of Saxe-Maſburg, and youngeſt daughter of the founder. The enſign of this order is a death's head enamelled white, ſurmounted with a croſs pattée ſable; above the croſs pattée another croſs, compoſed of five large jewels, by which it hangs to a black ribbon, edged with white; on the ribbon is this motto—MEMENTO MORI.

DEBA, in *Ancient Geography*, a river of Syria, which has its ſource to the north in the mountains, about lat. 39°, and running S.W. diſcharges itſelf into the Euphrates about lat. 37° 45′.

DEBA, a town of Aſia in Syria, ſituated in Comagené, upon a ſtream, to the S.W. of Doliche, and W. of Zeugma, about lat. 36° 25′.—Alſo, a town of Aſia, in Meſopotamia, ſituated on the Tigris. Ptolemy.

DEBALPOUR, in *Geography*, a town of Hindooſtan, and capital of a diſtrict in the country of Moultan, ſituated on the great road from Delhi to Moultan; 70 miles S.E. of Lahore, and 150 E. of Moultan.—Alſo a town of Hindooſtan, in the Malwa country; 21 miles W. of Endore, and 13 S. of Ougein.

DEBEN, a river of England, in the county of Suffolk, which riſes near Debenham, and runs into the ſea near Harwich. This river is navigable from its mouth to the town of Woodbridge. See CANAL.

DE BENE ESSE, a Latin phraſe uſed in our law-books. To take, or do, a thing de bene eſſe, is to accept, or allow it as well done for the preſent; but when it comes to be more fully examined, or tried, to ſtand or fall, to be allowed or diſallowed, according to the merit or well-being, of the thing in its own nature; or, as we ſay, "Valeat quantum valere poteſt."

Thus, in chancery, upon motion to have one of the leſs principal defendants in a cauſe examined as a witneſs, the court (not then thoroughly examining the juſtice of it, or not hearing what may be objected on the other ſide) often orders ſuch a defendant to be examined de bene eſſe, *i. e.* that his depoſitions ſhall be allowed, or ſuppreſſed, at the hearing of the cauſe upon a full debate of the matter, as the court ſhall think fit; but for the preſent they have a well-being, or conditional allowance. 3 Cro. 68. When a complainant's witneſſes are aged or ſick, or going beyond ſea, and the plaintiff is in danger of loſing their teſtimony, the court will order them to be examined de bene eſſe; ſo as to be valid if the plaintiff hath not an opportunity to examine them afterwards; as if they die before anſwer, or do not return, &c. In either of theſe caſes the depoſitions may be uſed in the court of chancery, or at law. Thus alſo in common law, the judges often take bail de bene eſſe, to be allowed or rejected upon the approbation or exception of the plaintiff's attorney. Declarations likewiſe are ſometimes delivered de bene eſſe.

DEBENHAM, in *Geography*, a market town in the hundred of Thredling, in the county of Suffolk, England; is diſtant from Ipſwich 12 miles, and 82 from London. It is ſituated on the ſide of a hill, which declines to the river Deben. The church is a handſome ſtructure, and the market houſe a good building. Here is a free ſchool founded by ſir Robert Hitcham. In the year 1744, the town ſuffered ſeverely by fire. It has a ſmall market on Fridays, and one annual fair on the 24th of June. The number of houſes appears, by the returns made under the late act, to have been 392, and of inhabitants 1215.

DEBENTURE, a public written acknowledgment of money due, for value received or ſervices performed, ſomewhat ſimilar to a bond. They were firſt iſſued in this country in 1649, by the commonwealth, for ſecuring to the ſoldiers, or their aſſigns, the ſums due to them for pay, upon the accounts being audited; and they have been ſince iſſued to the army, purſuant to ſeveral acts of parliament, likewiſe to the ſervants of the king's houſhold for ſalaries, board-wages, &c.

In 1700, the debentures which had been iſſued for arrears due to the officers of the army, and for tranſport ſervice, and for clothing the army, were directed to be taken as ſterling money, in purchaſes of the forfeited eſtates in Ireland of perſons convicted of treaſon; but this proviſion being inſufficient, 5 *per cent.* intereſt was allowed on the debentures, till the principal part of them was ſubſcribed into the original capital of the South Sea company.

In 1711 debentures were iſſued by the commiſſioners for trade and plantations, to the proprietors and inhabitants of the iſlands of St. Chriſtopher and Nevis, who had ſuffered greatly by the invaſion of the French, in 1705. Theſe debentures carried 6 *per cent.* intereſt, but it was not paid very regularly: a part of them was paid off, and the remainder ſubſcribed into 3 *per cent.* ſtock.

Debentures have ſince been occaſionally iſſued for temporary purpoſes; thus, after the concluſion of the American war, compenſations were granted to ſuch perſons as had been ſufferers from their attachment to the Britiſh government, who, upon their claims being inveſtigated, received debentures bearing $3\frac{1}{2}$ *per cent.* intereſt, afterwards commonly called loyaliſt debentures, which in the whole amounted to about £2,000,000, and were gradually diſcharged at ſubſequent periods.

Debentures are iſſued by the Board of Ordnance to perſons contracting for ſtores, or other articles, in that department. They are not payable at any fixed period, and as they do not bear intereſt, thoſe who have occaſion to diſpoſe of them are generally obliged to ſell them at a diſcount, which has ſometimes been very conſiderable. In the years 1784 and 1785, it was thought proper to provide for the principal part of the ordnance debentures then outſtanding, by funding them in 5 *per cent.* ſtock.

DEBENTURE, in *Commerce*, a certificate iſſued by the officers of the cuſtoms, entitling the exporter of goods to a bounty or drawback of duty, purſuant to act of parliament. In order to obtain the debenture, it is neceſſary, with reſpect to foreign produce, to trace the articles on which the

allowance

allowance is claimed through all the different hands into which they have paſſed ſince their importation, in order to prove that the duty has been actually paid thereon; the exporter is likewiſe required to give a bond, as ſecurity that the goods ſhall not be re-landed in any part of the United Kingdom.

Debentures, whether for a drawback or a bounty, undergo a variety of formalities and examinations, and muſt have a number of ſignatures to render them complete. They are made out by the collector outwards; thoſe for drawbacks from a certificate ſigned by the clerk of the certificates that the duties under their ſeveral branches upon the articles entered for exportation therein enumerated, have been paid; thoſe for bounties, from the bond given by the merchant for the exportation of the goods ſpecified in the entry. The goods on which either the drawback or the bounty is computed, are thoſe certified by the ſearchers to have been actually ſhipped. On a debenture for a drawback, the duties to be paid back are computed, and endorſed in figures, by the clerk of the rates; the controller checks this computation. The examiner computes, and inſerts them in figures upon the back of the debenture, with the titles of the different branches, and the amount in words at length. On a debenture for a bounty, the collector outwards, computes, and enters, at different times, the ſeveral branches, with the amount in figures and in words at length: the controller, ſurveyor, and ſurveyor-general, ſucceſſively check this computation.

Debentures, like moſt other public documents, are liable to a ſtamp duty.

DEBET, among *Book-keepers*, is uſed to expreſs the left-hand page of the ledger, to which are carried all articles ſupplied or paid, on the ſubject of an account.

Debet et Detinet, in *Law*, are Latin words, denoting, *he oweth and detaineth*, uſed in the bringing of writs and actions; and an action ſhall always be in the debet et detinet, when he who makes a bargain or contract, or lent money to another, or he to whom a bond is made, bringeth the action againſt him who is bounden, or party to the contract and bargain, or unto the lending of the money, &c. But if a man ſells to another a horſe, &c. if he brings debt for the horſe, the writ muſt be in the detinet only. New. Nat. Br. 265.

Debet et Solet, are alſo formal words made uſe of in writs; and ſome writs have theſe words in them, which ought not to be omitted. Likewiſe, according to the diverſity of the caſe, both debet et ſolet are uſed, or debet alone: as a quod permittat may be in the debet et ſolet, or in the debet only, as the demandant claims. And if a perſon ſues to recover any right, whereof his anceſtor was diſſeiſed, by the tenant or his anceſtor, then he uſeth the word debet alone in his writ, becauſe his anceſtor only was diſſeiſed, and the eſtate diſcontinued: but if he ſue for any thing that is now firſt of all denied him, then he uſeth debet et ſolet, becauſe his anceſtor before him, and he himſelf uſually enjoyed the thing ſued for, until the preſent refuſal of the tenant. Reg. Orig. 140. The writ of ſecta molendini is a writ of right in the debet et ſolet, &c. F. N. B. 98.

DEBILITY, in *Medicine*, is a term of ſomewhat extenſive application, being uſed by medical writers, not only to denote the diminution of the muſcular powers of the body, but alſo to deſignate the failure of the due performance of the functions in all the organs reſpectively.

Thus Dr. Cullen, treating of fever, obſerves, that the ſymptoms, which denote a great degree of debility, are, in the *animal* functions; the weakneſs of the voluntary motions; the irregularity of the voluntary motions, depending on their debility; the weakneſs of ſenſation; the weakneſs and irregularity of the intellectual operations:—in the *vital* functions; the weakneſs of the pulſe; the coldneſs or ſhrinking of the extremities; the tendency to a deliquium animi, in an erect poſture; the weakneſs of reſpiration:—in the *natural* functions; the weakneſs of the ſtomach, as appearing in anorexia, nauſea, and vomiting; involuntary excretions, depending on a palſy of the ſphincters; and difficult deglutition, depending on a palſy of the muſcles of the fauces. Firſt Lines, § 104.

The term debility is alſo applied to every diminution of the powers of the ſyſtem, although originating in circumſtances altogether different in their nature. The weakneſs, for example, which ſucceeds acute diſeaſes, or which is produced by ſpare diet, or other means of privation of the ſupport of the body; and the loſs of ſtrength which is occaſioned by the operation of contagion, or other cauſes of fever, and of narcotic ſubſtances, which ſuddenly impair the energy of the brain, are both denominated debility. The latter ſtate has, however, by ſome writers, been termed, proſtration of ſtrength, to diſtinguiſh it from the actual loſs of the ſubſtance of the body, which accompanies the former.

Debility holds an important ſtation in the ſyſtem of Dr. Brown, commonly called the Brunonian ſyſtem, in which it is uſed in a peculiar acceptation. Debility, according to Brown's hypotheſis, is the cauſe of all diſeaſes, and is of two kinds, which he terms *direct* and *indirect* debility. As health conſiſts of a proper balance of ſtimuli, with excitability of the animal body, according to this hypotheſis; ſo, when the ſtimuli are in proportion too powerful, the excitability is exhauſted and *indirect* debility enſues; and when the ſtimulation is proportionately too feeble, the excitability is accumulated, and debility is the conſequence; which is called *direct* debility; becauſe it is not produced by any poſitive noxious power, but by a ſubduction of the things neceſſary to ſupport life." Brown's Elements of Medicine, chap. iii. § 45.

Dr. Darwin has placed theſe two conditions of the body in a ſimilar light, in his Zoonomia. If the quantity of ſenſorial power, he obſerves, remains the ſame, and the quantity of ſtimulus be leſſened, a weakneſs of the fibrous contractions enſues, which may be denominated *debility from defect of ſtimulus*. If the quantity of ſtimulus remains the ſame, and the quantity of ſenſorial power be leſſened, another kind of weakneſs enſues, which may be termed *debility from defect of ſenſorial power*: the former is the direct debility, the latter the indirect debility of Dr. Brown. See Zoonomia, vol. i. ſect. xii. 2. 1.

The ſubjects of direct debility, or debility from defect of ſtimulus, are perſons in a ſtate of inanition, from hunger; or who have been expoſed to ſevere cold, which is, in fact, an abſtraction of the ſtimulus of heat. On the contrary, thoſe perſons ſuffer indirect debility, or debility from exhauſtion of the ſenſorial power, who have been over ſtimulated: as thoſe who have experienced a debauch, from exceſſive potation of wine the preceding night; or thoſe who have been expoſed to exceſſive heat. Habitual drunkards ſuffer under this ſpecies of debility every morning, before they take their uſual potation, as is evinced by the tremors of their hands, their lowneſs of ſpirits, &c.

Through the whole progreſs of *indirect debility*, ſays Dr. Brown, the ſecond application of every ſtimulus has leſs effect than the firſt, the third leſs than the ſecond, and ſo forth to the laſt, which produces no more excitement; this effect takes place in proportion to the degree or duration of the ſeveral applications, though each gives ſome excitement.

Hence before the eſtabliſhment of indirect debility, and juſt as it is upon the eve of being eſtabliſhed, the ſtimulus, which is producing it, ſhould be withdrawn; a debilitating power ſhould be applied; as in giving over drinking wine at the

the end of an entertainment, and ſubſtituting water in its place, or applying cold to a perſon who has been expoſed to an exceſſive degree of heat. The progreſs to indirect debility is alſo retarded by diminiſhing the excitement from time to time, and proportionately increaſing the excitability, and thereby giving more effect to the action of ſtimuli.

In the cure of indirect debility, whatever be its degree, and from whatever ſort of exceſſive ſtimulus it has ariſen, little leſs of the ſtimulus, which is to be employed as the chief remedy, than that, which produced the diſeaſe, ſhould at firſt be uſed; and then leſs and leſs, till the diſeaſe is cured. Thus a man who has injured his conſtitution by the abuſe of ſpirituous liquors, is not ſuddenly to be reduced to water alone, as is the practice of ſome, but he is to be treated, as the judicious Dr. Pitcairn, of Edinburgh, is ſaid to have treated a highland chieftain, who applied to him for advice in this ſituation. The doctor gave him no medicines, and only exacted a promiſe from him, that he would every day put in as much wax into the wooden *queich*, out of which he drank his whiſkey, as would receive the impreſſion of his arms. The wax thus gradually accumulating, diminiſhed daily the quantity of the whiſkey, till the whole *queich* was filled with wax; and the chieftain was thus gradually, and without injury to his conſtitution, cured of the habit of drinking ſpirits.

The cure of the hurtful effect of any ſtimulus, ſhould be firſt ſet about by changing it for a leſs; this for a ſtill leſs; and the intention of cure ſhould be always to paſs from the uſe of the more violent and diffuſible, which nature in her healthy ſtate rejects, to that of the more durable, till the healthy ſtate can at laſt be maintained by the uſual means.

Through the whole courſe of *direct debility*, or debility from defect of ſtimulus, every deficiency of ſtimulus is increaſed by a ſecond, the ſecond by a third, the third by a fourth, till the effect at laſt comes to be a ceſſation of any further excitement. Excitement, therefore, in ſuch caſes, is never to be leſſened, and debility increaſed, with the view of giving greater effect to a new ſtimulus, by accumulating excitability. For as often as this is put in practice, the morbid ſtate is increaſed; and, if the debility ſhould happen to be great, any further increaſe may induce death, but will never increaſe the ſtrength. For the cure of direct debility, we ſhould begin with the ſmalleſt degree of ſtimulus, and then riſe to the uſe of a greater and greater, till the morbid abundance of excitability be gradually worn off, and health at laſt reſtored.

This may be illuſtrated in the effects of intenſe cold, or abſtraction of heat. When a limb is benumbed by cold, if heat be ſuddenly applied a ſevere pain is produced, which, if the ſtimulus of heat be continued, will be followed by violent inflammation, terminating in mortification; the direct debility being ſuddenly converted into indirect debility by over-ſtimulation, while the excitability was redundant. The ſafeſt mode of reſtoring a froſt-bitten limb is to begin with the loweſt degree of ſtimulus, ſuch as gentle friction with ſnow, and gradually proceed to warmer applications, as the excitability diminiſhes, until it is reduced to the uſual ſtandard, and can bear the uſual ſtimuli. This is the practice of the Ruſſians, and the inhabitants of cold countries in general. See Cold.

The phenomena of ſtarvation from want of food alſo illuſtrate this ſubject. It has been found by experience to be abſolutely neceſſary to begin the uſe of aliment in the moſt cautious manner, otherwiſe inflammation of the ſtomach is the conſequence. Food, not only the moſt ſparing in quantity, but of the mildeſt and leaſt ſtimulating nature, is to be firſt adminiſtered, to be repeated at ſhort intervals, and gradually increaſed both in quantity and nutritious quality; by which means the powers of the ſtomach are at length brought back to bear the uſual ſtimuli.

Thus far the theory of direct and indirect debility is the reſult of a correct generalization of facts, and ſerves us as a fundamental principle in the treatment of many morbid conditions of the human conſtitution. But in attempting to extend it, as the baſis of an explanation of all diſorders, the Brunonians have quitted the path of induction, and ſubſtituted analogies of their own creation, for thoſe which they ought to have found in the phenomena of nature. See Excitability.

DEBIN, in *Geography*, a town of Arabia, in the country of Yemen, 38 miles E. of Chamir.

DEBIR, in *Ancient Geography*, called *Kirjath ſepher*, the city of letters, and *Kirjath-arba*, a city of Judah, near Hebron. It was taken by Joſhua, and fell by lot to Caleb. It belonged to the Levites, Joſh. x. 39. xii. 13. xv. 15, 16. xxi. 15. 1 Chron. vi. 58 —Alſo, a town of Gad, beyond Jordan, Joſh. xiii. 26.—Alſo, a city of Benjamin, which had belonged to Judah, Joſh. xv. 17.

DEBIS, in *Mythology*, a Japaneſe idol, repreſented under a human form of gigantic ſtature, as an image of braſs, placed on the moſt conſpicuous part of a high road, without a temple or pagoda. The young women who viſit this idol in order to be informed when they ſhall have huſbands, receive an anſwer from a prieſt who is placed in the hollow of it. Some gratuity is expected in conſequence of this ſuppoſed communication with the god.

DEBLATHAIM, in *Ancient Geography*, a town which belonged to the Moabites, and the ruin of which was predicted by Jeremiah. Ch. xlviii. v. 2.

DEBLAW, in *Geography*, a town of Bohemia, in the circle of Chrudim; 4 miles S. S. W. of Chrudim.

DEBORAH and Barak, a female and a male judge of Iſrael, who, after Siſera, general of the Canaanites, was defeated and ſlain by Jael, ſung a hymn or canticle of thankſgiving. B. C. 1285.

DEBORUS, in *Ancient Geography*, a town of Macedonia, in Pæonia; called by Thycydides *Doberus*.

DEBRA Libano, in *Geography*, a town of Abyſſinia; 180 miles S. of Gondar.

Debra Selalo, a town of Abyſſinia; 90 miles S. W. of Gondar.

Debra Semona, a town of Abyſſinia; 110 miles S. of Gondar.

DEBRETZIN, Debrezen, Debrechen, Debrecinum, a large and populous town of Auſtria, in Upper Hungary, in the county of Bihar, 54 miles S. E. of Tokay; 54 miles N. of Great Waradin; 105 miles E. of Buda. N. lat. 47° 30′.

Debretzin, though it has the title and privileges of a town, muſt be conſidered as a village, and then it is perhaps the greateſt village in Europe, as it contains 30,000 inhabitants. But ſhould it be conſidered as a town, it is one of the worſt, though its inhabitants are not poor. It is ſurrounded with a hedge, and the town gates are like Engliſh field gates, ſtuck with thorns and brambles. The houſes, with only a few exceptions, conſiſt merely of the ground floor; they are thatched, and have the gable-end turned towards the ſtreet. The ſtreets are not paved, but in a few of the moſt frequented balks are laid down in the middle for the foot paſſengers.

By far the greateſt part of the inhabitants are Calviniſts. Their principal college is at Debretzin. The building is irregular, old and decaying. The ſtudents are very numerous.

Debretzin is famous for its ſoap manufacture, its bread, a woollen

woollen cloth called *guba*, its pipes, and its quarterly fairs. The ſoap is ſent all over Hungary, and even to foreign countries. It is made from natural mineral alkali or natron, called ſzekſo. This is found as an efflorescence on a ſandy ſoil in many parts of Hungary, but particularly about a lake near Kiſ-maria, which is only a few miles from Debretzin. It is not purified, nor does it undergo any operation before it is uſed.

There is alſo near Debretzin an imperial ſaltpetre manufactory, and juſt without the town there are a few vineyards, but they yield a very poor wine.

Debretzin is alſo remarkable for its horned cattle. As a proof of the greatneſs of its herds, Korabinſky mentions in his Lexicon, that a certain biro is ſaid often to have driven ten thouſand head of cattle upon the neighbouring common; and that in the year 1739, when, on account of the ſeverity and length of the winter, a ſcarcity of fodder prevailed, and more than eight thouſand were ſlaughtered; they were never miſſed. Dr. Robert Townſon's Travels in Hungary, chap. ix.

DEBREW, a ſmall town of Hungary, famous for its tobacco leaves, which generally ſell 12 or 15 per cent. higher than any other Hungarian tobacco.

DEBRUIZED, or DEBRUISED, in *Heraldry*, is when we would intimate the grievous reſtraint of any animal, which is debarred its natural freedom by any of the ordinaries being laid over it.

Thus when a pale, &c. is borne upon a beaſt in an eſcutcheon, the beaſt is ſaid to be *debruiſed* by the pale.

DEBT, a thing due to another, whether it conſiſt of money, goods, or ſervices.

The legal acceptation of debt is a ſum of money due by certain and expreſs agreement: as, by a bond for a determinate ſum; a bill or note; a ſpecial bargain; or a rent reſerved on a leaſe, that is fixed and unalterable. The nonpayment of theſe is an injury, for which the proper remedy is by action of debt, to compel the performance of the contract, and recover the ſpecific ſum that is due.

This is the ſhorteſt and ſureſt remedy; particularly where the debt ariſes upon a ſpecialty, that is, upon a deed or inſtrument under ſeal. Thus alſo, if I verbally agree to pay a man a certain price for a certain parcel of goods, and fail in the performance, an action of debt lies againſt me; for this is a determinate contract; but if I agree for no ſettled price, I am not liable to an action of debt, but a ſpecial action on the caſe, according to the nature of my contract. Actions of debt are now ſeldom brought but upon ſpecial contracts under ſeal, in which the ſum is clearly and preciſely expreſſed; for in caſe of ſuch an action upon a ſimple contract, the plaintiff labours under two difficulties: 1ſt, the defendant hath here the ſame advantage as in action of *detinue*, that of waging his law, or purging himſelf of the debt by oath, if he thinks proper (4 Rep. 94.); 2dly, in an action of debt the plaintiff muſt prove the whole debt he claims, or recover nothing at all. For the debt is one ſingle cauſe of action, fixed and determined; and which therefore, if the proof varies from the claim, cannot be looked upon as the ſame contract, the performance of which it ſues for. However, in actions of debt, where the contract is proved or admitted, if the defendant can ſhew that he has diſcharged any part of it, the plaintiff ſhall recover the reſidue. 1 Roll. Rep. 257. Salk. 664. The various caſes in which action of debt lies are too numerous to be here recited. (See Jacob's Law Dict. by Tomlins, art. *Debt.*)

The form of the writ of debt is ſometimes in the *debet* and *detinet*, and ſometimes in the *detinet* only; that is, the writ ſtates, either that the defendant owes and unjuſtly detains the debt or thing in queſtion, or only that he unjuſtly detains it. It is brought in the *debet* as well as *detinet*, when ſued by one of the original contracting parties, who perſonally gave the credit, againſt the other who perſonally incurred the debt, or againſt his heirs, if they are bound to the payment; as by the obligee againſt the obligor, the landlord againſt the tenant, &c. But, if it be brought by or againſt an executor, for a debt due to or from the teſtator, this not being his own debt, ſhall be ſued for in the *detinet* only. (F. N. B. 119.) So alſo, if the action be for goods, for corn, or an horſe, the writ ſhall be in the *detinet* only; for nothing but a ſum of money, for which I (or my anceſtors in my name) have perſonally contracted, is properly conſidered as my debt. And, indeed, a writ of debt in the *detinet* only, for goods and chattels, is neither more nor leſs than a mere writ of *detinet*; and is followed by the ſame judgment. Raſt. Entr. 174.

By our law, debts due to the king are to be ſatisfied in the firſt place in all caſes of executorſhip, and adminiſtratorſhip; and till the king's debt be ſatisfied, he may protect the debtor from the arreſt of any other creditor. At the common law, debt lies not for rent upon a leaſe for life, though it doth on a leaſe for years; but the remedy is aſſiſe, if the plaintiff have ſeiſin, or by diſtreſs. (3 Rep. 65.) But by ſtat. 8 Anne, c. 17. any perſon having rent in arrear, upon any leaſe for life or lives, may bring action of debt for ſuch rent, as where rent is due on a leaſe for years. Action of debt will lie againſt a leſſee, for rent due after the aſſignment of the leaſe; for the perſonal privity of contract remains, notwithſtanding the privity of eſtate is gone. (3 Rep. 22.) But after the death of the leſſee, it is then a real contract, and runs with the land. Cro. Eliz. 555.

It behoves an executor or adminiſtrator to pay regard to the priority of debts in diſcharging them; otherwiſe, on deficiency of aſſets, he muſt anſwer thoſe of a higher nature out of his own eſtate: ſuch are funeral charges, and expence of proving the will; debts to the king on record or ſpecialty; debts, which by particular ſtatutes are to be preferred to all others, as forfeiture for not burying in woollen, money due on poor's rates, letters to the poſt office, and ſome others; debts of record, as judgments, ſtatutes, and recognizances; debts due on ſpecial contracts, as for rent, on bonds, covenants, &c. under ſeal; and laſtly, debts on ſimple contracts, as notes and verbal promiſes, and ſervants' wages.

As any contract, by which a determinate ſum of money becomes due to any perſon, and is not paid, but remains in action merely, is a contract of debt, we have various kinds of debts; and they are uſually divided into debts of *record*, debts by *ſpecial*, and debts by *ſimple* contract.

A *debt of record* is a ſum of money which appears to be due by the evidence of a court of record. Thus, when any ſpecific ſum is adjudged to be due from the defendant to the plaintiff, on an action or ſuit at law, this is a contract of the higheſt nature, being eſtabliſhed by the ſentence of a court of judicature. Debts upon recognizance, are alſo a ſum of money recognized or acknowledged to be due to the crown or a ſubject, in the preſence of ſome court or magiſtrate, with a condition that ſuch acknowledgment ſhall be void upon the appearance of the party, his good behaviour, or the like: and theſe, together with ſtatutes merchant and ſtatutes ſtaple, &c. if forfeited by nonperformance of the condition, are alſo ranked among this firſt and principal claſs of debts, *viz.* debts of record; ſince the contract, on which they are founded, is witneſſed by the higheſt kind of evidence, *viz.* by matter of record.

Debts by ſpecialty, or ſpecial contract, are ſuch by which a ſum of money becomes, or is acknowledged to be due, by deed or inſtrument under ſeal. Such as, by deed of covenant,

nant, by deed of ſale, by leaſe reſerving rent, or by bond or obligation. Theſe are looked upon as the next claſs of debts after thoſe of record, being confirmed by ſpecial evidence under ſeal.

Debts by ſimple contract, are ſuch, where the contract, upon which the obligation ariſes, is neither aſcertained by the matter of record, nor yet by deed or ſpecial inſtrument, but by mere oral evidence, the moſt ſimple of any; or by notes unſealed, which are capable of a more eaſy proof, and (therefore only) better than a verbal promiſe. There is one ſpecies of debts upon ſimple contract, which is diſtinguiſhed by the now well-known appellation of "paper-credit." Theſe are debts by *bills of exchange*, and *promiſſory notes*, which ſee reſpectively.

DEBT, *Information of*. See INFORMATION.

DEBT, *Chirographary*, in the *Ancient French Law*, is that due by virtue of a note, or writing under one's hand, and not proved in judicature.

DEBT, *Hypothecary*, is that due in virtue of ſome contract or judgment.

DEBT, *Prædiatory*, is that ariſing from an alienation of lands, &c. the whole purchaſe whereof has not been paid.

DEBT, *Privileged*, is that which muſt be ſatisfied before all others; as the king's tax, &c.

DEBTEE EXECUTOR. If a perſon, debtor to another, makes his creditor or debtee his executor, or if ſuch creditor obtains letters of adminiſtration to his debtor, he may retain ſufficient to pay himſelf before any dther creditors whoſe debts are of equal degree. Blackſt. Com. vol. iii. p. 18. See EXECUTOR and RETAINER.

DEBTOR, a perſon who owes ſomething to another: in oppoſition to creditor, which is he to whom it is owing. Concerning the treatment of inſolvent debtors by the 12 tables, &c.; ſee BANKRUPT.

DEBTS, PRIORITY OF. See EXECUTOR.

DEBTS, *Public*, are debts entailed by a government upon the induſtry and reſources of poſterity, in order to provide for the preſent exceſs of the expenditure above the ordinary revenue of a country. In the earlier periods of the different ſtates of Europe, the annual expences both of the civil and military adminiſtration appear to have been always raiſed within the year. The former, indeed, were altogether inconſiderable, and the latter, whenever they occurred, in conſequence of being thus directly paid by the people, were ſpeedily checked by the difficulty of providing for them. But ſince the ſyſtem of *borrowing* has been adopted, and government have been obliged to provide no more than the annual intereſt of the money which they expended, wars have not only been multiplied and protracted, but rendered more expenſive by the facility with which the means of maintaining them have been ſupplied; and hence debts and taxes have accumulated till they have involved moſt of the nations which have had recourſe to them in diſtreſs and ruin.

In Great Britain this ſyſtem of borrowing, though hitherto exempt from the conſequences which it has produced in other countries, has been carried to a much greater extent, and its progreſs ſeems to have been accelerated in proportion as the debt has become more enormous; ſo that, during the laſt fifteen years, it has almoſt *tripled* the accumulation of the preceding century, and the ſum now annually raiſed for the mere payment of the *intereſt* would have nearly diſcharged the whole *principal* of the debt, at a time when the nation was in fear of being overwhelmed by the weight of it.

The government of this country may, perhaps, have been neither more frugal nor more attentive to the intereſts of the people *before*, than they have been *ſince*, the revolution; yet it is certain, that at the death of Charles II., and even at the expulſion of his ſucceſſor, the nation was encumbered with no other debt than that of 664,263 to the bankers, which was charged upon the hereditary exciſe in the 12th of king William, and of 60,000*l.* to the ſervants of Charles II., which was provided for in the firſt ſeſſion of parliament after the revolution. But, in conſequence of the continued wars during the whole of king William's reign, above 61 millions were voted by parliament for the public expenditure; and on the 31ſt of December, 1701, the nation was encumbered with a permanent debt of 6,748,780*l.* the annual intereſt on which amounted to 566,165*l.* In the following reign, the ſame ſyſtem of expending and borrowing was purſued without the leaſt intermiſſion. The grants of parliament, in the courſe of 13 years, exceeded 80 millions; and at the death of queen Anne in 1714, the debt amounted to 50,644,306*l.* requiring 2,811,903*l.* to be annually raiſed in taxes on the property and labour of the people, towards paying the intereſt of it.

On the acceſſion of George I. the nation appears to have been ſo ſeriouſly alarmed at the magnitude of the debt, and to have felt ſo impatient under the burthens which it had impoſed upon them, that they conſidered the public expenditure as having nearly exhauſted the reſources and deſtroyed the credit of the country. The earlieſt attention of government, therefore, was engaged in arranging the finances, and applying remedies to the evils which they threatened to the public peace and ſecurity. Such of the taxes as were only temporary were made perpetual, and the funds which had hitherto been blended together, without order or diſtinction, were divided into four claſſes, and were appropriated to the following purpoſes: 1ſt. The Aggregate Fund, to the payment of intereſt on money due to the bank of England, and on other debts, and alſo to the payment of 120,000*l.* *per ann.* for the uſe of the civil liſt. 2dly. The South Sea Fund, to the payment of intereſt on the capital of the South Sea company. 3dly. The General Fund, to the payment of intereſt on 7,808,087*l.* ſtock in the South Sea annuities—and 4thly. The Sinking Fund, which, conſiſting of the ſurplus of all the taxes, after diſcharging the intereſt, &c. in the three former claſſes, was to be regularly applied to the payment of the national debt. During a few years after the eſtabliſhment of theſe funds, the application of them was attended to with conſiderable care and vigilance; and the improvement of the ſinking fund, in particular, was recommended to parliament in ſpeeches from the throne, with the ſame zeal as it was echoed back in the addreſſes of the houſe of commons. (See FUNDS.) But as the operations of this fund did not commence till the year 1719, and they were never aſſiſted by any economy in the adminiſtration of the finances, they produced but little effect during the remaining part of this reign; ſo that, although the nation, through the whole courſe of it, was engaged in no wars of any conſequence, the debt, inſtead of being reduced, was increaſed, on the 31ſt of December, 1727, (or in ſix months after the deceaſe of George I.) to 52,092,235*l.*: but, in conſequence of the reduction of *intereſt* on ſome part of this debt, the annual amount of the taxes neceſſary to provide for the ſame, was only 2,363,564*l.*, or 448,339*l.* leſs than at the cloſe of the preceding reign.

When George II. ſucceeded to the throne, the nation was in a ſtate of peace, or, at leaſt, was under the neceſſity of providing for no other extraordinary expenditure than about 300 000*l.* a year in foreign ſubſidies, towards preſerving the balance of power, and ſecuring the king's dominions in Germany. Nevertheleſs, the miniſter who had aſſumed ſo much credit in eſtabliſhing the ſinking fund, and who had

had ſo often repreſented it as abſolutely neceſſary to ſave the nation from ruin, was the firſt to lay violent hands upon it, by appropriating a million of its produce to the ſupplies of the year;—a practice thus ſhamefully begun was continued without intermiſſion in the following years, and the alienation of this fund became as conſtant and invariable as the prodigal waſte and extravagance that produced it. Hence the nation, though diſturbed by no foreign wars during the firſt 13 years of that reign, and therefore expoſed to no extraordinary expenditure, derived little or no relief from a fund, which, if honeſtly applied in that time, and aſſiſted by public economy, would have diſcharged the greateſt part of its debts. At the end of the year 1739, therefore, when the clamours of the commercial part of the country forced the government into a war with Spain, the capital of the debt amounted to 46,382,650*l* ; and at the concluſion of that war, in 1749, which terminated with a general reſtitution of conqueſts, it had accumulated to 78,166,906*l*., leaving the trade of the country encumbered with additional cuſtoms and exciſe, and the nation, in regard to its foreign poſſeſſions, exactly in the ſame ſtate as at the commencement of the war. From this period, to the beginning of the next war, the ſinking fund, inſtead of being aſſiſted in its operations by any economy in the management of the public finances, was invariably alienated towards providing for the ordinary ſupplies of the year, ſo that, during an interval of eight years' peace, only 3,089,641*l*. of the debt were redeemed, which did not amount to *one tenth* part of what had been incurred by the preceding war.

In the year 1756, the nation became again involved in hoſtilities, in conſequence (as M. Voltaire obſerves) of ſome diſputes about a few acres of ſnow in North America, and the public debt, which at the commencement of that war amounted to 75,071,264*l*., had accumulated, at the death of the late king in 1761, to 110,604,836*l*.; and at the general peace in 1763, it amounted to 146,582,844*l*., requiring 4,840,821*l*. to be annually raiſed in taxes towards paying the intereſt of it; a ſum conſidered at that time as too heavy to be borne by the people of Great Britain; and hence the miniſter directed his views to the colonies in North America, with the hope of making them bear a part at leaſt of the burdens which oppreſſed the mother country. As early therefore as the month of March 1764, it was reſolved in the houſe of commons, at the inſtigation of the miniſter, that it would be proper to impoſe certain ſtamp duties in the colonies for the purpoſe of raiſing a revenue in Great Britain; and in the year 1765 this reſolution was paſſed into a law. Thus, having juſt terminated a foreign war, the ſeeds were immediately ſown for kindling a civil one. It would be improper, in the preſent article, to trace the progreſs of the violence on one ſide, and of reſiſtance on the other, which mutually exaſperated the two countries; and it will be ſufficient only to obſerve here, that the flames of war burſt forth in the beginning of the year 1775. At that period, though the nation had enjoyed an external peace for more than twelve years, the debt was not reduced as many millions; for, at the commencement of the war, it amounted to 135,943,051*l*., or only to 10,639,193*l*. leſs than its amount in 1763; ſo that in proportion as the public burthens increaſed, the efforts of miniſterial economy to relieve them appear to have become more feeble and inefficient. After having extended its ravages to both ſides of the globe, by drawing France, Spain, and Holland into an alliance with America, this war, begun for the oſtenſible purpoſe of leſſening the public burthens, by forcing the colonies to ſhare in them, terminated, like all other wars, without obtaining its object, and by increaſing thoſe burthens more than twofold. The whole of the funded debt in January 1784 amounting to 232,152,803*l*., and the unfunded debt to more than 36 millions, requiring an annual revenue of 9,560,907*l*. for the mere payment of intereſt upon it, excluſive of taxes, for the ordinary expences of the peace-eſtabliſhment, which had alſo increaſed nearly in the ſame proportion.

In this year commenced the adminiſtration of Mr. Pitt, which is diſtinguiſhed for having added more to the public debts than all the adminiſtrations that have ever exiſted ſince the revolution. By the bad management of his predeceſſors, the unfunded debt had now accumulated beyond all example. The greater part of this enormous maſs was converted into a permanent debt in 3, 4, and 5 *per cents*. The former diviſion of the revenue into the *General*, the *South Sea*, the *Aggregate*, and the *Sinking Fund*, was diſcontinued; the whole of the taxes were collected together into one fund, called the *Conſolidated Fund*, and one million of the ſurplus of thoſe taxes, after diſcharging the intereſt of the debt, &c. was to be appropriated annually towards redeeming the principal. During the firſt ſeven years, however, after this new arrangement of the finances, no ſuch ſurplus really exiſted (although the public were amuſed with the belief of it), and the deficiencies were made up by loans; by the receipt of balances in the hands of the collectors, and other adventitious means; ſo that at the end of nine years of peace, the nation, ſo far from being relieved of any of its burdens, found itſelf loaded with a permanent debt of 260,892,756*l*., excluſive of what remained unfunded, amounting to many millions more. It muſt, however, be obſerved, that this interval of peace had been diſturbed at different times, by provocations to hoſtilities with Holland, Ruſſia, and Spain, and that the expenditure in conſequence had been increaſed by the warlike preparations of the miniſter. But certainly the additional expences incurred on theſe occaſions were not to ſuch an extent as to account for the inſufficiency of the public income, and to juſtify him in aſſerting that it was more than equal to the ordinary expenditure of a peace eſtabliſhment. It is, however, a matter of little moment at preſent on which ſide of the account the balance then lay. The debts have ſince ſwollen into ſuch a ſtupendous maſs as to render the ſurplus or the deficiency of a few millions in the revenue, an object neither of hope on the one hand, nor of apprehenſion on the other.

In the year 1793, the government, alarmed at the progreſs of the French revolution, plunged the nation into a war, the moſt calamitous and expenſive that ever deſolated the population, or deſtroyed the reſources of the country; from which it juſt emerged at the end of eight years, to ſink deeper than ever into a gulph which has ſwallowed up all the old governments on the continent of Europe, and which the warmeſt and ſtouteſt of our own cannot contemplate without anxiety. From the commencement of this war, to the ceſſation of hoſtilities in 1801, a term diſtinguiſhed above all others in the annals of this country, by the greateſt waſte of the public treaſure, and the moſt improvident extravagance in contracting the public loans, the debt had accumulated ſo far beyond all former example, that at the final cloſing of the accounts in April, 1803, it amounted, after deducting 67 millions which had been redeemed by the ſinking fund, to a capital of 531,769,159*l*. requiring 24,564,811*l*. to be annually raiſed in taxes towards paying the intereſt, excluſive of the ſums neceſſary for the intereſt upon the unfunded debt, and for the expences of the civil and military eſtabliſhments, amounting at leaſt to twelve millions more, and making the whole peace eſtabliſhment to exceed 36 millions *per annum*.

Encumbered with ſuch an immenſe weight of debts and

taxes, incurred for the moſt part in the ſupport of wars deſtructive of the beſt intereſts of the country, it was to have been hoped that peace, ſo highly neceſſary to heal the wounds, and relieve the burdens under which it laboured, would have been ſuffered to remain a few years at leaſt undiſturbed; but unfortunately this hope has been diſappointed. The rejoicings on the termination of one war had hardly been finiſhed, before the kingdom was plunged into all the miſeries of another; which, having raged with unabated violence and expence for more than five years, without affording the moſt diſtant proſpect of being concluded, renders it impoſſible at this time to determine to what greater ſum the debts may be accumulated. The following ſtatements, therefore, deduced from the accounts which were laid before parliament in March, 1808, are confined to the end of the preceding year; but they exhibit a picture of itſelf ſufficient to alarm the nation, without being reminded of the many additional millions, which have been borrowed and expended in the preſent year.

Amount of the Public Debt on the 1ſt of February, 1808.

46,184*l.* annuities on lives granted prior to, and during the preſent reign, ſuppoſed to be worth about 7 years purchaſe - -		£323,288
Sum ſubſcribed in 1766 for annuities with benefit of ſurvivorſhip - - - -		18,000
Ditto ſubſcribed in 1789 for ditto - -		1,002,099
1,047,494*l.* annuities expiring in 1860, valued at 5*l. per cent.* - - - - -		19,292,700
Stock in the 3 *per cents.*	£590,091,288	
Redeemed by the commiſſioners	125,177,702	
		464,913,586
Stock in the 4 *per cents.* -	49,425,085	
Redeemed by the commiſſioners	2,617,400	
		46,807,685
Stock in the 5 *per cents.* -	44,830,742	
Redeemed by the commiſſioners	142,000	44,688,742
Imperial Loans.		
Stock in the 3 *per cents.* -	7,502,633	
Redeemed by the commiſſioners	829,426	
		6,673,207
230.000*l.* annuities for 13 years, valued at 5 *per cent.* - - - - - -		2,160,505
Whole of the funded debt - -		£585,879,812

Unfunded Debt, not provided for on the 5th of January, 1808.

Exchequer bills -	£31,942,900	
Treaſury warrants, &c. -	727,101	
Barracks and ordnance -	1,252,182	
Navy - - - -	6,561,237	
Civil Liſt advances - -	50,430	
		40,533,850
Whole of the funded and unfunded debt of Great Britain - - - -		626,413,662

As Ireland now conſtitutes a part of the united kingdom, its debts may not improperly be added to the preceding account, and are as follow:

Stock in the 3 *per cents.* -	47,139,625	
Redeemed by the commiſſioners	4,628,926	
		42,510,699
Carry over		42,510,699
91,208*l.* annuities expiring in 1860, valued at 5 *per cent.*		1,679,870
		44,190,569
Brought over		626,413,622
Whole of the funded and unfunded debt of the united kingdom - - -		£670,604,231

Amount of the Sums neceſſary to be raiſed in Taxes towards defraying the annual Charge of the National Debt.

Intereſt on the unredeemed part of the debt -	£19 014,619	
Annual appropriation for the redemption of the debt - - -	9,338,814	
Annual charges of management - -	272,948	
		£28,626,382
Intereſt on the unredeemed part of the imperial loans	432,792	
Annual appropriation for the redemption of the debt - - -	22,287	
Charges of management -	5,645	
		460,724
Intereſt on exchequer bills - -		1,574.362
Whole amount of the ſums to be annually raiſed on account of the debts of Great Britain - - -		£30,661,468
Intereſt on the unredeemed part of the Iriſh debt -	£1,253,840	
Annual appropriation for the redemption of the debt - -	118,064	
Charges of management	19 163	
		1,391,067
Whole amount of the ſums to be annually raiſed on account of the debts of the united kingdom of Great Britain and Ireland - - - - -		£32,052,535

In addition to theſe ſums, about 40 millions are neceſſary to be raiſed in each year towards providing for the civil and military eſtabliſhment, which, of courſe requiring new loans and taxes, are continually adding to the permanent burdens of the kingdom; nor is it eaſy to determine to what further extent their weight may be increaſed by the preſent war. They have already far exceeded what the moſt ſanguine had conceived it poſſible for the nation to ſupport; and the debt has long ago over-paſſed the bounds which had been aſſigned to public credit. A continued progreſſion, however, in the ſame career of expence muſt at laſt terminate in that ruin which the more timid may perhaps have anticipated too ſoon, but which by being protracted, will only be rendered more general and deſtructive. See on this ſubject "The Hiſtory of our Debts and Taxes." Dr Price's Tracts on the National Debt. Mr. Morgan's Tracts on the Public Finances &c. &c.

DEBTS *and Credits*, in *Military Language*. Every captain of a troop or company, in the Britiſh ſervice, is directed to give

give in a monthly ſtatement of the "debts and credits" of his men; and it is the duty of every commanding officer to examine each liſt, and to ſee that no injuſtice or irregularity has been countenanced or overlooked in ſo important an object, as every money-matter between officer and ſoldier moſt unqueſtionably is.

DEÇA, in *Geography*, a river of Spain, which runs into the Xalon, two leagues below Anza in Aragon.

DECACHORDON, in *Antiquity*, a muſical inſtrument, of ten ſtrings, called by the Hebrews *haſur*, reſembling our harp, of a triangular figure, with a hollow belly, and ſounding from the lower part.

DECACTIS, in *Natural Hiſtory*, a name given by ſome to a kind of ſtar-fiſh, of the branched, or aſtrophyte kind, whoſe rays are ten in number, where they firſt part from the body, and each ſoon branches out into a number more.

DECADARCHUS, Δεκαδαρχος, among the Greeks, a commander of a party of ten men.

DECADE, a word uſed by ſome old writers for the number ten; and decades, for an enumeration by tens: the word is formed from the Latin decas, which is derived from a Greek word of the ſame import. The word has been more peculiarly appropriated to the number of books, *q. d.* decades into which the Roman Hiſtory of Titus Livius is divided. Hence alſo came decadal arithmetic, the Decameron of Boccaccio, &c.

DECAGON, a plain figure in geometry, having ten ſides and angles. If all the ſides and angles be equal, it is called a regular decagon, and may be inſcribed in a circle; for the method of doing which, ſee PENTAGON. If AB, (*Geometry*, *Plate* VI. *fig.* 74.) be the ſide of a regular decagon inſcribed in a circle, whoſe radius is AD, the radius will be a mean proportional between the ſide of the decagon and the ſum of that ſide and the radius: *i. e.* AB: AD :: AD: AD + AB. Produce AB to F, ſo that BF may be equal to AD, and draw DF and DB, then the angle ADB, being at the centre and ſubtended by the ſide of a decagon, is $= \frac{1}{10}$ of four right angles, or $\frac{1}{5}$ of two right angles, and therefore DAB + DBA $= \frac{4}{5}$ of two right angles, and ABD (= DAB) $= \frac{2}{5}$ of two right angles = (as the external angle) BDF + BFD = (the triangle BDF being iſoſceles) 2 BDF; and therefore BDF or BFD $= \frac{1}{5}$ of two right angles = ADB. Conſequently the triangles ADB and ADF are ſimilar, F being = ADB, and A being common, and therefore AF or AB + BD (=AD): AD :: AD: AB.

Hence it appears that if the radius be cut in extreme and mean proportion, the greater ſegment is the ſide of the decagon AB. For, by diviſion, $\overline{AB + AD} - AD$, *i. e.* AB: AD :: AD − AB: AB, or AD: AB :: AB: AD − AB, ſo that AD is ſuppoſed to be cut in extreme and mean proportion. See EXTREAM and *Mean Proportion*. It alſo appears that the radius is to the ſide of the decagon as 2 to $\sqrt{5} - 1$. For the rectangle of the extremes being equal to the ſquare of the mean, we have $AB^2 + AB \times AD = AD^2$, and adding $\frac{1}{4} AD^2$, $AB^2 + AB \times AD + \frac{1}{4} AD^2 = \frac{5}{4} AD^2$, and $AB + \frac{1}{2} AD = \frac{AD\sqrt{5}}{2}$, and $AB = \frac{AD}{2}\sqrt{5} - \frac{AD}{2}$, and 2 AB $= AD \times \sqrt{5} - 1$. Therefore AD: AB :: 2: $\sqrt{5} - 1$. Or, by an algebraic proceſs, and the ſolution of a quadratic equation, making AD $= a$, and AB $= x$, we have $x^2 + ax = a^2$, and completing the ſquare, $x^2 + ax + \frac{1}{4} a^2 = a^2 + \frac{1}{4} a^2 = \frac{5a^2}{4}$; and, by extracting the ſquare root, $x + \frac{1}{2} a = \sqrt{\frac{5}{4} a^2}$, and $x = \sqrt{\frac{5}{4} a^2} - \frac{1}{2} a$; and ſuppoſing radius 1, x, or the ſide of a decagon inſcribed in the circle, $= \sqrt{\frac{5}{4}} - \frac{1}{2} = \frac{\sqrt{5} - 1}{2}$, and $2x = \sqrt{5} - 1$., and 1: x :: 2: $\sqrt{5} - 1$, as before; or the ſide of the inſcribed decagon $= \sqrt{\frac{5 - 1}{2}} \times r$, r being radius.

If the ſide of a regular decagon be 1, its area will be $\frac{5}{2}\sqrt{5 + 2\sqrt{5}} = 7.6942088$; therefore, as 1 is to 7.6942088 ſo is the ſquare of the ſide of any regular decagon to the area of the ſame; ſo that if s be the ſide of ſuch a decagon, its area will be equal to $7.6942088\, s^2$. See REGULAR *Figure*, and POLYGON.

DECALITRON, among the *Ancients*, a piece of money uſed by the people of Ægina, Corinth, and Syracuſe, in value equal to $16\frac{2}{3}$ oboli of Athens.

DECALOGUE, the Ten Commandments of God, engraven on two tables of ſtone, and given to Moſes.

The word is Greek, compoſed of δεκα, *ten*, and λογος, *word*, *q. d. ten words*. Accordingly the Jews call them עשרת דברים, *the ten words*, which appellation is very ancient.

The Samaritans, both in their text and verſion, add after the ſeventeenth chapter of the twentieth chapter of Exodus, and after the twenty-firſt verſe of the fifth chapter of Deuteronomy, an eleventh commandment, to build an altar on mount Gerizim, &c. But it is apparently an interpolation, to authorize their having a temple and an altar on that mountain; and to diſcredit, if poſſible, the temple at Jeruſalem, and the worſhip there performed. It muſt be added, however, that though all, both Jews and Chriſtians, agree in the number of Ten Commandments, there is ſome difference as to the manner of dividing them.

The Talmudiſts, and Poſtellus, after them, in his treatiſe "De Phœnicum Literis," ſay, that the Decalogue, or Ten Commandments, were engraven quite through the tables which God gave to Moſes; but that nevertheleſs the middle of the ם *Mem* final, and of the ס *Samech*, remained miraculouſly ſuſpended without adhering to any thing. See the Diſſertation on the Samaritan Medals, printed at Paris in 1715. They add, that the Decalogue was written in letters of light, *i. e.* in luminous ſhining letters.

The Decalogue was originally delivered in two tables; one of which contains our duty to God, expreſſed in the four firſt commandments; and the ſecond, our duty to our neighbour, enforced in the ſix laſt. The church of Rome, for a very obvious reaſon, hath omitted the ſecond commandment in many of her books; and in order to preſerve the number complete, divided the laſt into two. It is omitted not only in the ſhort catechiſms and manuals of the Romiſh church; but in the reformed office of the bleſſed virgin, printed at Salamanca, A. D. 1588, publiſhed by order of Pius V.; and alſo in the Engliſh office at Antwerp, A. D. 1658. See Stillingfleet's Works, vol. vi. p. 572.

DECAMERIS, a term ſignifying a tenth part; uſed by Mr. Sauveur, and ſome other authors, to mark and meaſure the intervals of ſounds.

The word is formed of δεκα, *ten*, and μερις, *part*.

In Mr. Sauveur's ſyſtem, the decameris is the tenth part of the heptameris, which he makes the ſeventh part of the meris; and this is the forty-third part of the octave; ſo that the decameris is $\frac{1}{3015}$ of an octave. See Mem. Acad. Scienc. 1701. and 1707.

DECAMERON, from δεκα, *ten*, and ημερα, *day*; a work containing the actions or converſations of ten days. Boccacio's Decameron conſiſts of one hundred novels related in ten days.

DECAMPMENT, in a *Military Senſe*, relates to the removal of troops from a place where they were encamped, or quartered. When the intention has been previouſly known, little precaution is uſed to conceal the movement, and the orders are, for the moſt part, iſſued one, or more, days before the army commences its march. At the hour appointed for ſtriking the tents the drums beat *the general*, which is the ſignal univerſally known for a removal of quarters; ſo much ſo indeed, that whenever *the general* is beat through the camp, or town, the whole prepare for marching by ſtriking the tents, loading the baggage, harneſſing the cattle, limbering the cannon, and all the various operations attendant upon ſuch a change of locality. When the notice has been long given, it is uſual to allow from half to a full hour, between beating the general, and beating *the aſſemblée*; under the ſuppoſition that all would be duly prepared, and that a very ſhort interval of time would ſuffice for thoſe ſeveral matters which are inevitably delayed to the laſt moment. But when the decampment is rather ſudden, and it has not been practicable to call in various detachments, out-poſts, &c. the time between the *general* and the *aſſemblée* is uſually extended, perhaps to two or three hours, to allow the warning to be generally known, and that every thing may be completed for removal.

Decampments ariſing from emergency, ſuch as the intelligence of riots, &c. in neighbouring towns, or of an intended ſurpriſe by a party of the enemy, are commonly announced by beating *to arms*, on which ſignal, every one repairs to his poſt, and the means of attack, of reſiſtance, or of retreat, become the firſt conſideration. When this happens in conſequence of an expected aſſault, and that it is found expedient to retire before a ſuperior force, the baggage, &c. is ſent forward, and the troops act as an eſcort, or covering-party; where riots, &c. demand the preſence of the troops elſewhere, the baggage is either ordered to follow with all due circumſpection and activity, under a ſmall guard; or it is left, as it is technically termed, "on the ground," (*i. e.* at the place quitted by the troops,) to await further orders.

Decampments made for ſecret purpoſes, ſuch as a night attack upon an enemy, or for the purpoſe of avoiding an attack, or for changing the poſition of a line unknown to the enemy, ſo that he may be deceived, either by having to oppoſe a greater force than was expected, or by finding that poſt vacated, towards which he had beſtowed a large portion of his force, thus thrown out of the line of action; are uſually made *without beat of drum*. And in order to carry on the intended deception, it is not uncommon to leave a few horſemen to keep up the ordinary fires; to challenge the approaching troops; or to appear, when the decampment is known to the enemy, as the rear, or baggage-guard, and thus to lead them into a purſuit; ſo that they may either fall into an ambuſcade, or be more completely detached from their main body, and eventually be cut off. In fact, we are not to conſider decampment as the mere act of removal from one quarters, camp, or poſition, to another; but as one of thoſe *ruſes de guerre*, which often give a complete turn to the poſture of affairs, and have been known to change the campaign into a new direction, as well as to give it a new aſpect. This device was one of the moſt ſucceſsful, among the many exerciſed, againſt our commanders, by the great Waſhington: perhaps it would he difficult to quote any inſtances in European warfare, that could bear a competition for ſkill, and allurement, with thoſe practiſed by that worthy and brave general. Nor have the French, during their late ſucceſſes among the ſubdued ſtates of Europe, been a little indebted to this deception; whether by bribery, by ignorance, or by want of prudence, our allies have on various occaſions ſuffered partly by this *ignis-fatuus* ſyſtem; and when they thought it was impoſſible for the object of clandeſtine attack to eſcape, have found their rear ſuddenly aſſaulted by the very troops they judged to be ſome miles diſtant in their front.

Hence our readers will perceive that decampment may be occaſionally conſidered rather as an evolution, than as a mechanical operation; and that, when well conducted, it often affords the means of avoiding intended miſchief, and of ſeverely retaliating on the enemy.

DECAMYRON, in the *Medicinal Writings of the Ancients*, the name of a maiagma or cataplaſm, conſiſting of ten different kinds of aromatics: theſe were the Indian leaf, maſtic, euphorbium, ſpikenard, adarce, ſtorax, pepper, ointment of nard, opobalſamum, and wax.

DECANDRIA, in *Botany*, the tenth claſs of plants, with hermaphrodite flowers, and ten ſtamina, or male parts in each.

The word is formed of the Greek δεκας, *ten*, and ανηρ, *male*.

Of this claſs of plants there are five orders; *viz.* the *monogynia*, containing fifty-three genera; the *digynia*, comprehending twelve genera; the *trigynia*, eleven; the *pentagynia*, fourteen; and the *decagynia*, two genera.

DECANTATION, is the act of pouring a liquor off clear from the dregs or ſediment.

DECANUS, among the Romans, an officer who had ten other officers, or perſons, under his charge; whence our Engliſh dean. See Dean.

Decanus, in *Aſtrology*, a title given to the god who preſided at any birth, ὁ ὡροσκοπος. See Astrology.

DECAPITE', in *Heraldry*. See Defait.

DECAPOLIS, in *Ancient Geography*, a country of Paleſtine, which contained 10 principal cities, ſome on this and ſome on the other ſide of Jordan, whence the name. Pliny enumerates the following: Scythopolis, Philadelphia, Raphanæ, Gadara, Hippos, Dion, Pella, Geraſa, Canatha, and Damaſcus. Others reckon them differently. They were chiefly inhabited by the Gentiles, though ſome of them might be within the region of Judæa.

DECAPROTI, Decemprimi, among the *Ancients*, were officers who gathered the tributes, or taxes.

The word comes from δεκα, *ten*, and πρωτος, *firſt*; probably becauſe the ten firſt, or principal perſons of each community, were choſen to make the levies.

The decaproti were obliged to pay for the dead; or, to anſwer to the emperor for the quota of ſuch as died, out of their own eſtates. Cicero, in his oration for Roſcius, calls them decemprimi.

DECASMUS, Δεκασμος, in *Antiquity*, the name of an action or proceſs among the Athenians, which was brought againſt any perſon who offered a bribe. They thought it not enough to puniſh the perſon receiving a bribe, but that the perſon who offered it ought to be puniſhed likewiſe. Pott. Archæol. Græc. lib. i. c. 23.

DECASPERMUM, in *Botany*. See Psidium.

DECASTADIUM, in *Ancient Geography*, a town of Italy in Brutium, at its ſouthern extremity, S. of Rhegium, and on the ſame coaſt.

DECASTYLE, in *Architecture*. A temple is ſaid to be decaſtyle,

decaſtyle, when its portico contains ten columns in a linei front: From δεκα. *ten*, and στυλος. *column*.

DECATARIA, in *Ancient Geography*, a town of Illyria in Dalmatia.

DECCAN, in *Geography* a general term, ſignifying the *South*, but applied by the Indian geographers to the countries that lie ſouth of the parallel of 21° or 22° of N. lat. and compriſing nearly one half of the tract generally known by the name of the Mogul empire, ſo that the Deccan and peninſula are about equal to the Britiſh Iſlands, Spain, and Turkey in Europe. The Deccan, in its moſt extenſive ſignification, includes the whole peninſula ſouth of Hindooſtan proper; but in its limited ſenſe and ordinary acceptation, it denotes only the countries ſituated between Hindooſtan proper, the Carnatic and Oriſſa, that is, the provinces of Candeiſh, Amednagur, or Dowlatabad, Viſiapour, Golconda, or Biſnagur, and the weſtern part of Berar. Many attempts were made by the Mogul emperors, towards the cloſe of the 13th and commencement of the 14th century, for ſubduing the Deccan; but about the year 1344, when Mahomed III. was emperor, the princes of the Deccan aſſumed courage, and headed by Belaldeo, king of the Carnatic, drove the Mahomedans entirely out of thoſe countries; and nothing remained to them, except the fortreſs of Dowlatabad, or Deogur. About the beginning of the 16th century, the Portugueſe firſt accompliſhed the paſſage to India by the Cape of Good Hope, but their connexions were altogether with the maritime parts of the Deccan. As it had been long a ſtumbling-block to the Mogul emperors, Acbar, in 1585, reſolved on the attack of it, and ſoon after carried the war into Berar, while another army was reducing Caſhmere, in an oppoſite corner of the empire. However, at the time of Acbar's death, in 1605, no further progreſs was made in the reduction of the Deccan, and the adjoining countries, than the taking poſſeſſion of the weſtern part of Berar, Candeiſh, Tellingana (a diviſion of Golconda), and the northern part of Amednagur; the capital of which, bearing the ſame name, was taken in 1601, after a long and bloody ſiege, and an unſucceſsful attempt to relieve it, by the confederate princes of the Deccan. In the reign of Shah Jehan, who aſcended the throne in 1628, the conqueſt of the Deccan was vigorouſly purſued; and the plunders and devaſtations perpetrated there occaſioned moſt, or all of its princes to make ſubmiſſion, and acknowledge the emperor, lord paramount. Golconda was in part actually taken poſſeſſion of; but Viſiapour, and the Carnatic, together with the region of the Gauts, remained in the hands of their ancient poſſeſſors.

During the latter part of the reign of Aurungzebe, who diſdained to have any other boundary on the ſouth beſides the ocean, the conqueſt of the remote part of the Deccan employed a very conſiderable part of his leiſure; when the whole of that region, together with the peninſula, a few mountainous and inacceſſible tracts only excepted, were either entirely ſubjected, or rendered tributary to the throne of Delhi. What ſeemed to induce Aurungzebe to ſubdue the Deccan was the determined ſpirit and growing power of Sevajee, the founder of the Mahratta ſtate; who, by his conqueſts in Viſiapour, appeared almoſt under the character of a rival to Aurungzebe. Accordingly he was employed in the Deccan from the year 1678 to the time of his death, in 17 7. Deccan was erected into a vice-royalty or ſoubah, and at the time of the invaſion of Nadir Shah, the viceroy was Nizam-al Muluck, who preſerved an apparent independence, and whoſe juriſdiction extended from Burhampour to Cape Comorin, and eaſtward to the ſea. Six provinces depended on this prince, and the number of his ſubjects was eſtimated at 35 millions. The Mahrattas, however, are in poſſeſſion of the greater part; other diſtricts have from time to time been formed into ſeparate ſtates; and the conſtant revolutions in India, render the boundaries of each country uncertain. The poſſeſſions of the Nizam, or ſoubah of the Deccan, (a younger ſon of the famous Nizam-al-Muluck) comprize, as they are ſtated in major Rennell's Memoir, the province of Golconda, that is, the ancient province of Tellingana, or Tilling, ſituated between the lower parts of the courſes of the Kiſtnah and Godavery rivers, and the principal part of Dowlatabad; together with the weſtern part of Berar, ſubject to a tribute of a chout, or fourth part of its net revenue, to the Berar Mahratta. The Nizam has the Paiſhwah, or Poonah Mahratta, on the weſt and north-weſt, the Berar Mahratta on the north, the northern Circars on the eaſt, and the Carnatic, and the late Hyder Ally on the ſouth. His weſtern boundaries, during his wars with the Mahrattas, have been ſubject to continual fluctuation; but they are underſtood generally to extend more than 40 miles beyond the city of Aurungabad, weſtwards; and to come within 80 miles of the city of Poonah; and on the S.W. to go conſiderably beyond the river Beemah, and to the borders of Sanore-Bancapour. His capital is Hydrabad or Bagnagur, ſituated on the Mouſſi river, near the famous fortreſs of Golconda. The diſtricts of Adoni and Rachore, which were in the hands of Bazalet Jung, (brother to the Nizam,) during his life-time, are now in the hands of the Nizam. The ſourapour, or ſollapour-rajah, on the weſt of the Beemah river, together with ſome other rajahs, are his tributaries. Probably, ſays Mr. Rennell, (Memoir, Introd. p. 136.) the Nizam's dominions, including his tributaries and feudatories, are no leſs than 430 miles in length, from N. W. to S. E., by 300 wide. Till he took poſſeſſion of the Guntoor Circar in 1780, his dominions no where touched on the ſea-coaſt; but Guntoor has been ſince ceded to the India company. See CIRCAR.

DECCAN *Shabazpour*, an iſland of India, in the mouth of the Ganges. N. lat. 22° 30′. E. long. 98° 58′.

DECEATES, in *Ancient Geography*, the name of a people who occupied the eaſtern ſide of Gallia Narbonnenſis, near the Mediterranean ſea, according to Strabo and Pliny.

DECEATUM, the town of the Deceates, in Gaul, which belonged to the Liguri.

DECEBALUS, in *Biography*, one of the barbarian kings, who contended with the greateſt ſucceſs againſt the power of the Roman empire. He was raiſed to the throne of Dacia on account of his military talents, about the period in which Domitian was ſovereign of Rome. In the war that commenced about the year 86, he frequently defeated the Romans, with great ſlaughter; and in one inſtance, prevented, by ſtratagem, the enemy from advancing to his own capital, by felling a great number of trees, and covering their trunks with armour, ſo as to appear like ſoldiers. Shortly after Domitian ſought for peace, to which Decebalus acceded, upon condition that he ſhould receive from the emperor's own hand a diadem, and a yearly tribute under the form and title of a penſion, which was regularly paid till the time of Trajan, who not only refuſed to be tributary to the Dacians, but entered his country with a powerful army, and was completely victorious. Decebalus was obliged to ſubmit to very humiliating terms; for the ſake of peace, he agreed to give up his arms and diſmantle his fortreſſes. Scarcely, however, had the emperor departed before the Dacian king prepared for new hoſtilities, and defied the power of Rome: Trajan was again ſucceſsful, and Decebalus, who found himſelf unequal to the open conteſt, determined to deſtroy by treachery

and aſſaſſination him whom he durſt not meet in the field. For this purpoſe he perfidiouſly got poſſeſſion of Longinus, the favourite officer of the Roman emperor, and endeavoured, by bribes and by threats, to make uſe of him as the inſtrument of his maſter's death. Longinus preferred the life of his king to his own, and by poiſon freed himſelf from the power of his enemy. Trajan now built his celebrated bridge over the Danube, completely conquered Dacia, and took poſſeſſion of its capital. Decebalus, ſeeing no chance of eſcaping from the hands of the emperor, put an end to his own life; and with him terminated the independence of Dacia, which was aftewards a mere Roman province. He had concealed the vaſt treaſures which he had accumulated, but theſe were diſcovered to the conqueror, and were found more than equal to the expence of the war. In the early part of life Decebalus had the character of being equally wiſe in council, and prompt in action; ſkilful in all the manœuvres of war, poſſeſſed of vigour to improve a victory, and conſtancy to repair a defeat. Univ. Hiſt.

DECEIT, *Deceptio*, or *Dolus*, in *Law*, is uſed for any ſubtile, wily ſhift, or trick; to which may be referred all manner of craft, ſubtility, guile, fraud, ſleight, cunning, covin, colluſion, and practice uſed to deceive another by any means.

Deceit is an offence both by common law and by ſtatute. All practices of defrauding, or endeavouring to defraud, another of his right, are puniſhable by fine and impriſonment, ſometimes pillory, &c. (ſee CHEATS); and there is a writ called deceptione that lies for one who receives injury, or damage, &c.

Serjeants, counſellors, attornies, and others, chargeable with deceit are to be impriſoned a year and a day; alſo pleaders by deceit ſhall be expelled the court: ſtat. 3. Ed. I. c. 29.

An action of deceit will give damages in ſome particular caſes of fraud; and principally where one man does any thing in the name of another, by which he is deceived or injured; as if one brings an action in another's name, and then ſuffers a non-ſuit, whereby the plaintiff becomes liable to coſts; or where one obtains or ſuffers a fraudulent recovery of lands, tenements, or chattels, to the prejudice of him that hath right. As when by colluſion the attorney of the tenant makes default in a real action; or where the ſheriff returns that the tenant was ſummoned when he was not ſo, and in caſe he loſes the land, the writ of deceit lies againſt the demandant and alſo the attorney, or the ſheriff and his officers, to annul the former proceedings, and recover back the land. It alſo lies in caſes of warranty, and other perſonal injuries committed contrary to good faith and honeſty. But an action on the caſe, for damages, in nature of a writ of deceit, is more uſually brought on theſe occaſions. And indeed it is the only remedy for a lord of a manor, in or out of ancient demeſne, to reverſe a fine or recovery had in the king's courts of lands lying within his juriſdiction, which would otherwiſe be thereby turned into frank fee. And this may be brought by the lord againſt the parties, and *ceſtuy que uſe* of ſuch fine or recovery; and thereby he ſhall obtain judgment not only for damages (which are uſually remitted), but alſo to recover his court and juriſdiction over the lands, and to annul the former proceedings.

A writ of deceit lies not only againſt attornies, for loſſes ſuſtained by their default; but alſo againſt bakers, brewers, and other artificers, for not ſelling good commodities, or refuſing to perform a bargain: in all which caſes they are by ſtatute liable to penalties in proportion to their offence.

DECEIVED, in the *Manege*, is uſed when a horſe upon a demi-volt of one or two treads, working, for inſtance, to the right, and not having yet finiſhed above half the demi-volt, is preſſed one time or motion forwards with the inner leg, and then is put to a repriſe upon the left, in the ſame cadence with which he began. He thus regains the place where the demi-volt had been begun to the right, and works to the left. A horſe may in this manner be deceived on any hand. Guillet, Gen. Dict. p. i. in voc.

DECELEA, or DECELIA, in *Ancient Geography*, a town of Greeee, in Attica. It was taken and fortified by the Lacedæmonians in the 19th year of the Peloponneſian war. It lay N. E. of Athens, near the ſource of the Cephiſus.

DECEMBER, in *Chronology*, the laſt month of the year; wherein the ſun enters the tropic of Capricorn, and makes the winter ſolſtice.

In Romulus's year, December was the tenth month; whence the name, *viz.* from *decem*, ten: for the Romans began their year in March.

The month of December was under the protection of Veſta: Romulus aſſigned it thirty days; Numa reduced it to twenty-nine; which Julius Cæſar increaſed to thirty-one.

Under the reign of Commodus, this month was called, by way of flattery, Amazonius, in honour of a courteſan, whom that prince paſſionately loved, and had got painted like an Amazon; but it only kept the name during that emperor's life.

At the latter end of this month they had the Juveniles ludi, and the country people kept the feaſt of the goddeſs Vacuna in the fields, having then gathered in their fruits, and ſown their corn; whence ſeems to be derived our popular feſtival called harveſt-home.

DECEMBRIO, PIETRO CANDIDO, in *Biography*, a learned Italian, was born at Pavia, in 1399, and was at an early age appointed ſecretary to Philip-Maria Viſconti, duke of Milan, in whoſe ſervice he continued till the death of his noble maſter in 1447. He is celebrated in hiſtory as one of the moſt able and ſtrenuous defenders of the liberties of the Milaneſe. When they ignobly reſolved to ſubmit to the arms of Francis Sforza, he refuſed to accept the humiliating office of ſurrendering the city to the conqueror. When the cauſe of Milan was hopeleſs, he became apoſtolic ſecretary to pope Nicholas V., and removed to Rome. He was likewiſe at ſome period of his life, the date of which has not been exactly aſcertained, ſecretary to Alphonſo of Arragon, king of Naples. Notwithſtanding the buſineſs which theſe important offices devolved upon him, he found leiſure to do much in the cauſe of literature. He wrote the lives of Philip Maria Viſconti, and Francis Sforza, dukes of Milan, in the manner of Suetonius. He tranſlated "Appian's Hiſtory;" "Quintus Curtius," and the firſt ten books of Livy's Hiſtory. This was by the command of king Alphonſo. He tranſlated into Latin proſe, the hiſtory of Diodorus Siculus, and various other works of the ancients, and was author of many miſcellaneous pieces in proſe and verſe, in the Latin and Italian languages. He died at Milan in the year 1477, and was buried in the cathedral of St. Ambroſe. Gen. Biog.

DECEM-PAGI, in *Ancient Geography*, *Dieaze*, a place of Gaul, in Belgica Prima, belonging to the Mediomatrici, N. W. of Pons Saravi.

DECEMPEDA, Δεκαπους, *ten-feet rod*; an inſtrument uſed by the ancients in meaſuring.

The decempeda was a rule or rod, divided into ten feet; whence its name, from *decem*, *ten*, and *pes*, *pedis*, *foot*.

The foot was ſubdivided into twelve inches; and each inch into ten digits.

The

The decempeda was uſed both in meaſuring of land, like the chain among us; and by architects, to give the proper dimenſions and proportions to the parts of their buildings, which uſe it ſtill retains. Horace, lib. ii. od. 15. blaming the magnificence and delicacy of the building of his time, obſerves, that it was otherwiſe in the times of Romulus and Cato; that in the houſes of private perſons there were not then known any porticoes meaſured out with the decempeda, nor turned to the north to take the cool air.

DECEMSEPTIMA, in *Ancient Geography*, a town of Spain, belonging to the Coſetani, N. E. of Tarraco.

DECEM-TALES, in *Law*, a writ that iſſues directed to the ſheriff, whereby he is commanded to make a ſupply of jurymen, when a ſufficient number does not appear on a trial at bar.

DECEMVIRI, an order of annual magiſtrates among the Romans, created with a ſovereign power to draw up and make laws for the people; thus called, becauſe their number was ten.

To the decemviri was given all the legiſlative authority ever enjoyed by the kings, and after them by the conſuls. One among them had all the enſigns and honours of the function; and the reſt had the like in their turn, during the year of their decemvirate.

The decemviri were thoſe who drew up the laws of the Twelve Tables, called thence leges decemvirales, which for a conſiderable time were the whole of the Roman law. See TABLES.

In the year 302, the conſuls Appius Claudius Craſſinius, and T. Genucius Augurinus, being obliged to abdicate, the firſt decemviri were created; in the year following, ten new ones were appointed to ſucceed them; they at firſt behaved with great moderation, and adminiſtered juſtice to the people each every tenth day; the twelve faſces were carried before him who was to preſide, and his nine colleagues were attended by a ſingle officer, called *Accenſus*; they propoſed ten tables of laws, which were ratified by the people at the "Comitia curiata," in the compoſition of which they are ſaid to have had the aſſiſtance of one Hermodorus, an Epheſian exile, who ſerved them as an interpreter; and as two other tables ſeemed to be wanting, decemviri were again created for another year to make them; and in the year 304, another ſet was to have been choſen, but that the people roſe, made them lay down, and reſumed the conſuls. The exceſſive debauchery of Appius Claudius Craſſinius, one of the conſuls, who was firſt obliged to abdicate, and who had been choſen firſt decemvir three times, was the principal cauſe of all this. Cicero De Finib. lib. i. Livy, lib. iii. Halicarnaſſeus, lib. x. and Florus, lib. i. c. 24. relate the hiſtory.

The decemviral adminiſtration, however, it is to be obſerved, had not its firſt riſe at the time when the authority of the conſuls was devolved into the hands of the decemviri: for, during the interregnum that enſued after the death of Romulus, the management of affairs, which the ſenate then took upon them, is called by Halicarnaſſeus, lib. ii. decemviral, becauſe the ſenators, divided into tens, commanded each in their turn: that is, one of each ten, for five days ſucceſſively, having the faſces, lictors, &c. like the kings.

There were alſo military decemviri; and on divers emergencies, decemviri were created to manage and regulate certain affairs, after the ſame manner as boards of commiſſioners are appointed among us. Thus we find decemviri for conducting colonies; decemviri, who officiated as judges in caſes of litigation, under the quæſtor and prætor; decemviri for dividing the lands among the veteran ſoldiers; decemviri to prepare and preſide at feaſts in honour of the gods; decemviri to take care of the ſacrifices; and decemviri to keep the Sibyls books.

Sometimes, in lieu of decemviri, they only created ſeptemviri or triumviri, or duumviri, &c.

DECENNALIA, in *Antiquity*, feaſts which the Roman emperors held every tenth year of their reign, with ſacrifices, games, largeſſes, to the people, &c.

Auguſtus was the author of this cuſtom, which was afterwards imitated by his ſucceſſors.

At the ſame time they likewiſe offered vows for the emperor, and the perpetuity of his empire, called vota decennalia.

From the time of Antoninus Pius, we find theſe ceremonies marked on medals, PRIMI DECENNALES, SECUNDI DECENNALES. VOTA SOL. DECEN. II. VOTA SVSCEP. DECENN. III.

Theſe vows muſt have been made at the beginning of every tenth year; for on a medal of Pertinax, who ſcarcely reigned four months, we find VOTA DECENN. and VOTIS DECENNALIBUS.

Struvius is of opinion, that theſe vows took place of thoſe which the cenſor uſed to make in the times of the republic, for the proſperity and preſervation thereof. In effect, they were not only made in behalf of the prince, but alſo of the ſtate, as may be obſerved from Dion. lib. viii. and Pliny the younger, lib. x. ep. 101.

Auguſtus's aim in eſtabliſhing the decennalia, was to preſerve the empire, and the ſovereign power, without offence or reſtraint to the people. For, during the celebration of this feaſt, that prince uſed to ſurrender up all his authority into the hands of the people, who, filled with joy, and charmed with the goodneſs of Auguſtus, immediately delivered it to him back again.

DECENNARY, *Decennaria*, the limits or compaſs of ten friburghs, or, a town or tithing conſiſting originally of ten families of freeholders. Ten tithings compoſed an hundred. The inſtitution of decennaries (or frank-pledges) is aſcribed to Alfred. In theſe decennaries the whole vicinity or tithing of franks were mutually pledges for the good behaviour of each other. See DECINERS, and TITHING.

DECENNOVIUM, in *Ancient Geography*, a canal of 19 miles from Forum Appii to Terracina, on which Horace embarked in the night. The Decennovium mentioned by Lucan, Dion Caſſius, and Caſſiodorius, has been ſucceſſively ruined, reſtored, and obliterated. This canal, ſtrangely confounded by Cluverius with the river Uſens, has recently ſerved to drain the Pomptine marſhes, by which they are converted into excellent paſtures.

DECEPTION BAY, in *Geography*, a bay on the weſt coaſt of North America, in the North Pacific ocean. N. lat. 46° 10′. W. long. 124° 5′.

DECEPTION, *Cape*, a cape in Solomon's iſles. S. lat. 8° 32′ 30″. E. long. 157° 2′ 14″.

DECEPTIONE, in *Law*, a writ which properly lies for one that receives harm or damage, by him that does any thing deceitfully in the name of another.

This writ is either original or judicial. Old Nat. Br. fol. 50. Fitz. Nat. Br. fol. 95. See Bag. of Writs, fol. 112. and Reg. Judicial. See DECEIT.

DECETIA, in *Ancient Geography*, *Decize*, a town of Gaul, in Lyonnenſis prima. It belonged to the Æduani, and was ſituated on the Liger, S.E. of Noviodurum. See DECISE.

DECHALES, CLAUD FRANCIS MILLIET, in *Biography*, an excellent mathematician was born at Chamberry, the capital of Savoy, in 1611. He read lectures in the college

lege of Clermont, at Paris, for about four years, where he was highly reſpected for his ſcientific talents, and greatly beloved on account of the probity of his heart, and the excellence of his diſpoſition. From Paris he removed to Marſeilles, where he taught the art of navigation and the practical mathematical ſciences. He afterwards became profeſſor of mathematies in the univerſity of Turin. Here he died in the year 1678, at the age of 67. His edition of Euclid is well known in this country; in this he has omitted many propoſitions which he deemed of inferior importance, and he has explained the uſes of ſome of thoſe which he has retained. He is known alſo for treatiſes on fortification, and navigation; and other works on the practical ſciences. His works have been collected and publiſhed, as a complete courſe of mathematics, in four volumes, folio. He is chiefly eſteemed for the eaſy method which he had adopted of explaining and illuſtrating difficult ſubjects.

DECHLANA, in *Geography*, a town of Aſia in Albania.

DECIALES, a people of the maritime Alps, along the coaſts, W. of the Velauni.

DECIDUA TUNICA, in *Anatomy*, the external membrane of the ovum, including the embryo, with the placenta and the other membranes. For the diſcovery of this part we are indebted to Dr. William Hunter. He proved that it is produced by the veſſels of the uterus itſelf, after impregnation, and before the arrival of the ovum in the cavity of that organ: he explained how it formed the medium of communication between the mother and the new being, by adhering on one ſurface to the uterus, and receiving continuations of the uterine blood-veſſels; and on the other, by being applied over the ſurface of the ovum, and forming in one part the uterine portion of the placenta, which is intimately blended with the ramifications of the umbilical veſſels; he ſhewed that it is thrown off from the uterus after the birth of the child, with the ſecundines, and from that circumſtance gave it the name of decidua. He was alſo of opinion that it conſiſted of two portions, one lining the cavity of the uterus *(decidua uteri)*, and another reflected over the ovum *(decidua reflexa)*. For a more particular account of this membrane, ſee GENERATION, *Organs of*.

DECIDUOUS, in the general, expreſſes a thing apt and ready to fall.

DECIDUOUS *Leaves*, in *Vegetable Phyſiology*, are ſuch as fall off in autumn, or at the approach of winter, as in moſt trees and ſhrubs of cold climates, and ſome tropical ones; an entirely freſh crop being produced in the enſuing ſpring. In North America the ſeaſon in which this takes place derives its name from that circumſtance, and inſtead of autumn is univerſally called the *fall*. We are not, however, to ſuppoſe that the leaves of evergreen trees or ſhrubs are not as regularly changed as deciduous ones; the only difference is, that they laſt longer, thoſe of ſome trees being of biennial, others of triennial, or perhaps further duration, ſo that the branches are never ſtripped. The leaves of ſuch evergreens generally fall in ſummer, as ſoon as the young crop is fully grown, which may be obſerved in the fir tribe.

How the falling or ſeparation of leaves from their branches is accompliſhed, has long been greatly miſunderſtood. It is not always in conſequence of the injuries of autumnal froſt, for ſome trees have their appropriate period of defoliation, ſeemingly independent of external cauſes. The lime, *Tilia europæa*, commonly loſes its leaves before any froſt happens: the aſh, *Fraxinus excelſior*, ſeems, on the contrary, to wait for that event; and at whatever period the firſt rather ſharp froſt takes place, all its leaves fall at once. The fall of the leaf can be conſidered only as "a ſloughing or caſting off diſeaſed or worn-out parts," whether the injury to their conſtitution may ariſe from external cauſes, or from an exhauſtion of their vital powers. Hence a ſeparation takes place, either in the footſtalk, or, more uſually, at its baſe, and the dying part quits the vigorous one, which is promoted by the weight of the leaf itſelf, or by the action of autumnal winds upon its expanded form. Sometimes, as in the hornbeam, the beech, and ſome oaks, the ſwelling of the buds for the enſuing ſeaſon is neceſſary to accompliſh the total ſeparation of the old ſtalks from their inſertions. Sometimes trees or ſhrubs, naturally deciduous, retain their leaves through a milder winter than ordinary, and even accidental varieties, raiſed from ſeed, are occaſionally more diſpoſed to be evergreen than is natural to their ſpecies, witneſs the Privet, *Liguſtrum vulgare*. Du Hamel very juſtly obſerves that trees killed by any ſudden cauſe, as thunder, retain their leaves firmly upon the branches. The reaſon evidently is, that the vital principle, being perfectly extinguiſhed, cannot act to throw off the injured foliage. It is curious that Du Hamel, evidently very anxious, and greatly embarraſſed, to underſtand the fall of the leaf, ſhould not have hit upon this ſimple and evident explanation. S.

DECIDUOUS *Plants*, in *Gardening*, are all ſuch plants, whether of the tree or ſhrub kind, as ſhed or loſe their leaves, in the autumnal and winter ſeaſons.

It is a term which embraces a great variety of both the former and latter ſorts, in moſt of which the leaves begin to fall off in the autumn, and the whole are naked during the winter ſeaſon. Almoſt all the valuable timber and fruit trees are of this tribe, as well as the greateſt part of the ornamental trees and ſhrubs that are introduced in plantations and ſhrubberies. There are likewiſe ſeveral other plants that may be termed deciduous, from their ſhedding their leaves on the approach of winter. See FRUIT and FOREST *Trees*.

Trees and ſhrubs of this ſort are in general of hardy growth, being capable of ſucceeding well in the full ground in different ſituations according to their kinds. Particular deſcriptions of the different ſorts, as well as of their habits of growth, culture, management, and uſes, are given under the genus to which they reſpectively belong.

The proper ſeaſons for removing this kind of plants from the nurſery or other places, and planting them out where they are to remain, are either the early ſpring or autumn, according to the kind and the nature of the ſoil. In general, where the land is dry, the latter is the moſt proper and advantageous; but in the contrary circumſtances, the former may be the more adviſeable. In the planting out all trees, ſhrubs, and other plants of this ſort, ſufficiently large openings ſhould be formed for the roots to be conveniently bedded in, after having been ſuitably trimmed according to the kinds; and the mould be made fine and well mixed in with the roots, by ſlightly ſhaking the plants, and the ſoil then well trodden in about them. In the early plantings at both ſeaſons it is of much advantage, eſpecially when the weather is dry, to have them well watered occaſionally, and moſt of the ſorts ſhould be kept ſteady in their ſituations by proper ſtakes, as they never ſucceed well where this is not the caſe, from their roots being deſtroyed by being ſo much agitated by the winds.

DECIES TANTUM, a writ that lies on ſtat. 38. Ed. III. c. 12. againſt a juror, who hath taken money of either party for giving his verdict. It is ſo called from its effect, which is to recover ten times as much as he took.

It alſo lies againſt embraceors that procure ſuch an inqueſt. See EMBRACEOR.

DECIMA, or DEZIMA, in *Geography*, a ſmall iſland in the harbour of Nagaſaki, on the coaſt of Japan, ſituated in N. lat. 42°, and ceded to the Dutch.

DECIMA, *Ital.*, the interval of a *tenth*, in *Muſic*, or octave of the 3d major or minor. Decima, preceding or following an integer, has in Italian the force of ten in Engliſh: as undecima, 11; duodecima, 12; decima terzo, 13; decima quarta, 14; decima quinta, the 15th or double octave; decima ſeſta, the 2d tripled, or octave of the 9th; decima ſettima, or 17th, &c.

DECIMÆ, or DECUMÆ, *Tenths*, or *Tithes*, in *Roman Antiquity*, a tribute or impoſt, which formed one part of the vectigalia of the Romans, in the early times of the commonwealth, and was raiſed upon lands. When the Romans had conquered a people, either in or out of Italy, they deprived them of part of their territory, of which they diſtributed a portion among citizens, who ſettled there as a colony, reſerving the property of the reſt to the ſtate, which they farmed to particular perſons, upon condition of paying a tenth of the profits of ſuch lands to the Roman people. The tenths were not raiſed in the ſame manner in all the provinces. From ſome a certain quantity of grain, or a fixed ſum of money, was exacted, as in Spain and Africa; and this impoſt was called "vectigal certum," becauſe it was always the ſame, whether the year were good or bad, or the lands produced much or little. Other provinces, as Aſia, were treated more favourably, and paid only the tenth preciſely, ſo that the Roman people ſhared in the misfortune of barren years. Sicily was treated in the ſame manner, and, indeed, with ſtill greater indulgence. Corn was bought from Sicily, and alſo from the other provinces, under three different denominations: *viz.* "frumentum decumanum," which was the 10th of the corn produced by each huſbandman's lands, with which he was obliged to ſupply the Roman people *gratis*; "emptum," which was the corn bought by the Roman people for the occaſions of the ſtate, and on which they themſelves fixed the price; and "æſtimatum," which was the corn conſumed in the prætor's houſe, and with which the province was obliged to ſupply him: this he ſometimes received in money, and he fixed the value of it himſelf. The tenths of wine, oil, and the lower ſpecies of grain were alſo paid.

Thoſe who farmed the tithes, "decumani," were eſteemed the moſt honourable of the publicans or farmers general, as agriculture was eſteemed the moſt honourable way of making a fortune among the Romans. The ground from which tithes were paid, was alſo called "decumanus." (See Cicero in Verr.) But theſe lands were all ſold or diſtributed among the citizens at different times, and the land of Capua, the laſt by Cæſar. (Suet. Jul. 20. Cicero Att. ii. 16.

DECIMÆ. See TITHES.

DECIMAL, in a general ſenſe, denotes any thing that proceeds by tens, as decimal arithmetic, fractions, ſcales, &c.

DECIMAL *Arithmetic*, the art of computing by decimal fractions, firſt invented by Johannes Regiomontanus, about the year 1464, and uſed by him in the conſtruction of his tables of ſines; who thus introduced decimal parts in the room of ſexageſimals. They were alſo uſed by Ramus, in his Arithmetic, written in 1550; and before his time, by our countryman Buckley, and about the ſame time by Record. But the firſt perſon who wrote an expreſs treatiſe on decimals, was Stevinus, about the year 1582.

This kind of arithmetic, in a general ſenſe, may be conſidered as the common arithmetical computation in uſe, in which the decimal ſeries of numbers is adopted, or in which the places of the figures change their value in a tenfold proportion, being 10 times as much for every place more towards the left hand, or 10 times leſs for every place more towards the right hand; the place being ſuppoſed to be indefinitely continued, both to the right and left. In this ſenſe, therefore, the term comprehends both the arithmetic of integers, and decimal fractions. In a more limited ſenſe, however, it is reſtricted to the latter.

DECIMAL *fractions*, are thoſe whoſe denominator is 1, with one or more cyphers; as, 10, 100, 1000, 10000, &c. Thus, $\frac{5}{10}$, $\frac{6}{100}$, $\frac{7}{1000}$, &c. are *decimal fractions*.

In the writing of decimal fractions, we uſually omit the denominator, as only conſiſting of unity with cyphers annexed; and in lieu thereof, a point, or comma, called the ſeparatrix, is prefixed to the numerator. Thus, $\frac{5}{10}$ is written .5; $\frac{46}{100}$, .46. So .125 expreſſes a hundred and twenty-five parts of any thing ſuppoſed to be divided into a thouſand parts.

This ſeparatrix has been different according to the fancy of different authors; ſometimes it has been a ſemiparentheſis or ſemicrotchet, or a perpendicular bar, or the ſame with a line drawn under the figures, or ſimply this line itſelf, &c. The point or comma, now generally uſed, has ſometimes been placed near the upper part of the figures, which was done by ſir Iſaac Newton; and though it has been more commonly placed at the bottom, the other mode has the advantage of preventing the ſeparatrix from being confounded with other characters of ſeparation, particularly in large numbers, and alſo with mere marks of punctuation.

As cyphers on the right hand of integers increaſe their value decimally; as 2, 20, 200, &c. ſo, when ſet on the left hand of decimal fractions, they diminiſh the value decimally; as, 5, 05, 005, &c. when ſet on the left hand of integers, or on the right hand of decimals, they ſignify nothing, but only to fill up places; thus .5000 denotes only five tenths, and 0005. is only five units.

In ſetting down a decimal fraction without its denominator, the numerator muſt conſiſt of as many places as there are cyphers in the denominator; and if it has not ſo many figures, the deficiency muſt be ſupplied by ſetting before them as many cyphers as will make them ſo many; thus $\frac{3}{10}$ is .3, $\frac{14}{100}$ is .14, and $\frac{14}{10000}$ is .014, and $\frac{3}{10000}$ is .003, &c.

To reduce any vulgar fraction, as ſuppoſe $\frac{5}{8}$, *to a decimal fraction* of the ſame value: add cyphers at pleaſure to the numerator, and divide by the denominator; as thus,

8)5000(

.625

And therefore $\frac{625}{1000}$, or .625, is a decimal of the ſame value with the former fraction $\frac{5}{8}$.

Some vulgar fractions can never be reduced into decimals without defect; as $\frac{1}{3}$, &c. in thoſe caſes, the greater number of places the decimals are continued to, the more is the defect diminiſhed, in a tenfold proportion. Thus, $\frac{1}{3}$ expreſſed in decimals is .333333 *ad infinitum*.

Such decimals are very properly called circulating decimals, becauſe of the continual return of the ſame figures; and they may be called indeterminate or infinite decimals, by way of diſtinction from thoſe where the reduction leaves no remainder, and which are therefore called finite or determinate decimals. See REPETENDS.

By the rule above given, the parts of any integer may be eaſily reduced into decimals. Thus, 5*s.* is $\frac{5}{20}$, or .25 of a pound ſterling; 6*d.* is $\frac{6}{240}$, or $\frac{1}{40}$, *i. e.* .025 of a pound; and 5*s.* 6*d.* is .25 + .025 = .275*l.* Or the decimal of a mixed number may be readily obtained by reducing the number of the loweſt ſpecies to the decimal of the next above; add to this the number of that ſpecies, if there be

any, and reduce the ſum to the next higher ſpecies, adding to the number found the number of that ſpecies given in the queſtion; and thus proceed till you arrive at the propoſed integer; 4 *s.* 7 *d.* 3 *f.* are equal to .2322916 *l.* for 3 *f.* is $\frac{3}{4}$, or .75 *d.* to which add 7 *d.* and 7.75 is equal to $\frac{7.75}{12}$, or .645833, &c. *s.* to which add 4 *s.* and 4.645833, &c. is equal to $\frac{4.645833}{20}$, or .23229166 &c. *l.*

Or thus: write the numbers of different names or ſpecies in an orderly manner under one another, the leaſt being the uppermoſt, and on their left ſide draw a line: and let theſe be reckoned as dividends: Then, againſt each name on the left hand of the line, write the number, making one of its next ſuperior name; and let theſe, be the diviſors to the former dividends: Begin with the upper one, and write the quotient of each diviſion as fractions, on the right of the dividend next below it; and let this mixed number be divided by its diviſor; and the laſt quotient will be the decimal ſought. Thus, for the laſt example, 4 *s.* 7 *d.* 3 *f.*

4 | 3
12 | 7.75
20 | 4.645833, &c.
.23229166, &c. *l.*, the number required.

The ſame proceſs may be eaſily applied to the decimal parts of any other integer, as weights, meaſures, and time.

E. G. 1. Reduce 8 *oz.* 15 *dwt.* 18 *gr.* to the fractional part of a pound troy.

24 { 4 | 18
6 | 4.5
20 | 15.75
12 | 8.7875
0.732291 *lb.*, the anſwer required.

Note.—As 24 is too great a number to divide by in one line, it is broken into the parts 4 and 6, which multiplied together, make 24.

E. G. 2. Reduce 48′ 17″ 53‴ to the proportional part of a degree.

60 | 53
60 | 17.883333
60 | 48.298055
0.804967 *deg.*, the anſwer required.

The common operations in decimals are performed as in the vulgar rules, regard being had only to the particular notation, to diſtinguiſh the integral from the fractional part of a ſum.

In Addition and Subtraction of DECIMALS; the points being all placed under each other, the figures are to be added, and ſubtracted, as in common arithmetic; and when the operation is done, ſo many figures of the ſum, or the remainder, are to be noted for decimals, as there are places of decimals in the greateſt given numbers. An example will make this clear.

Addition of Decimals.

.43791	59.271
.792	15.040
.6124	3.791
.053	12.009
.10	7.5
.2	
2.19531	97.611

Subtraction.

From	67	.9
Take	29	.8754
Rem.	38	.0246
From	25	.1462
Take	13	.07
Rem.	12	.0762

For Multiplication of DECIMALS, obſerve to cut off juſt ſo many decimal parts from the product as there are decimals in both factors. The work is the ſame as in integers. Thus,

Multiplication of Decimals.

.1472	.365	3.650
.175	.122	621
7360	730	3 650
10304	733	73 00
1472	365	2190 0
.0257600	.044530	2266.650

Note. In the firſt and ſecond examples, the products only amount to ſix and five places; for which reaſon cyphers are prefixed to make up the number of decimal places in the two factors reſpectively.

Hence, to multiply a decimal by unit with any number of cyphers, is only to remove the ſeparatrix ſo many places to the right as there are cyphers annexed.

In Diviſion of DECIMALS, proceed in all reſpects as in dividing of integers; and, when the operation is done, mark as many places in the quotient for decimals, as, with the number of decimals in the diviſor, are equal to the decimal places of the dividend.

.22).8030(3.65	22)8.030(.365
66	66
143	1 43
132	1 32
110	1 10
110	1 10
..0	.. 0
22).8030(.0365	73.2(83.219(1.13
66	73 2
142	100 1
132	73 2
110	26 99
110	21 96
...	5 03

Hence, to divide a decimal by unity with any number of cyphers, is only to remove the ſeparatrix ſo many places to the left, as there are cyphers annexed.

But there are certain caſes in diviſion of decimals, which require ſome farther management; as, firſt, where the diviſor is a decimal fraction, and the dividend is an integer; add, or annex, as many or rather more cyphers to the dividend, than there are places in the diviſor; thus, .365)22 0000(60.2 For there being three places or decimals in the diviſor, and four in the dividend, there will be but one in the quotient. Secondly, Where the diviſor is a mixed number, and the dividend a whole number, add at leaſt as many cyphers to the dividend as there are places in the diviſor; thus, 36.5)22.0000(6.02. Thirdly, Wherever the diviſor is bigger than the dividend, annex cyphers to the latter; thus,

36.5)22.0000(.602.

For

For the Valuation of DECIMALS; multiply the given decimal by the number of parts contained in the propoſed integer, proceeding from the higher to the lower if there be a remainder, and you will have the value required at the left of the ſeparatrix. Thus, .785*l.* is equal to 15*s.* 8*d.* 1.6*f.*

.785	.78 of a yard = 2 feet,
20	4.08 inches.
s. 15.700	.78
12	3
d. 8.400	*f.* 2.34
4	12
f. 1.600	*in.* 4.08

DECIMAL *ſcales*, in the general, denote any ſcales divided decimally; but particularly certain ſcales of money, weights, aud meaſures, made from tables ſo called, to expedite decimal arithmetic, by ſhewing by inſpection the decimal fraction of any part of money, weight, or meaſure. See SCALE.

DECIMATION, a puniſhment which the Romans uſed to inflict on the ſoldiers who had quitted their poſt, raiſed a mutiny in the camp, behaved themſelves cowardly in the fight, or otherwiſe failed in their duty; for which every tenth man was put to death as an example to the reſt.

The manner of decimating was thus; the general aſſembled the whole camp; then the tribune brought to him thoſe that were guilty, and impeached, and reproached them with their cowardly actions and baſeneſs, in the preſence of the whole army; then putting their names into an urn, or a helmet, as many were drawn out as made the tenth part of the whole number, and theſe were put to the ſword, and the others ſaved.

This was called *decimare*, a word of the ancient Roman militia, who, to puniſh whole legions, when they had failed in their duty, ſometimes alſo made every tenth ſoldier draw lots, and put him to death as an example to the others.

As the Romans had their decimatio, they had alſo the viceſimatio, and centeſimatio, when only the twentieth or hundredth man ſuffered by lot.

This practice has been occaſionally recurred to in modern times; as, particularly, in France, for the puniſhment of the garriſon of Treves in 1675, who capitulated and ſurrendered that place in oppoſition to the remonſtrance of the marſhal de Crequi, who commanded there. There was alſo a decimation during the time of the uſurper in this kingdom in 1655.

DECIMIS *ſolvendis pro poſſeſſionibus alienigenarum*, in *Law*, a writ yet extant in the regiſter, which lay againſt thoſe that had farmed the priors aliens lands of the king, for the rector of the pariſh, to recover the tithe of them. Reg. of Writs, fol. 179.

DECINERS, DECENNIERS, or DOZINERS, derived from the French dizeine, *i. e.* decas, *ten;* in the ancient monuments of our *Law*, are ſuch as are wont to have the overſight and check of the friburghs, for the maintenance of the king's peace, the limits of whoſe juriſdiction were called decenna, becauſe it commonly conſiſted of ten houſholds, and dozein; and every perſon bound for himſelf and his neighbours to keep the peace, was ſtiled *decennier*. Bract. lib. iii. tract. 2. c. 15.

Theſe perſons ſeem to have had very large authority in the Saxon times; taking cognizance of cauſes within their circuits, and redreſſing wrongs by way of judgment. Thus Briton, "We will that all thoſe that are fourteen years old ſhall make oath, that they will be ſufficient and loyal to us; and neither be felons, nor aſſenting to felons; and we will, that all profeſs themſelves of this or that dozein, and make or ſuffer ſurety of their behaviour by thoſe or thoſe doziners, except religious perſons, clerks, knights eldeſt ſons, and women."

A dozein now ſeems to be no more than a leet; for in leets only this oath is adminiſtered by the ſteward, and taken by ſuch as are twelve years old and upwards.

DECIO, PHILIP, in *Biography*, an eminent lawyer, was born at Milan in 1453. At an early age he appears to have been devoted to the belles lettres, but the plague which broke out forced him from his native place and interrupted his ſtudies, when he was but 17 years of age. He retired to Pavia, and, at the deſire of his brother, who was already a profeſſor of the law, he reſolved to follow the ſame courſe of life. He ſoon diſplayed much talent and acuteneſs in diſputation. At Piſa he obtained a doctor's degree in 1476, and was immediately appointed to read lectures on the "Inſtitutions." He was now appointed lecturer extraordinary in the civil law, nnd ſurpaſſed all his contemporaries, in whatever was connected with the duties of his profeſſion. His great reputation excited the jealouſy of his rivals, and he thought it prudent to remove to Sienna, where he had not been long before he was invited to Rome, to accept an office under the pope, which, as it would have rendered holy orders indiſpenſable, he declined, and reſumed the profeſſor's chair at Sienna. From Sienna he went to Piſa, and from thence he went to Padua, where he became profeſſor of canon law; and ſo deſirous were perſons to hear him, that the other ſchools were deſerted, and people of the higheſt rank became his conſtant auditors. When Milan fell under the power of France, Louis XII. reclaimed Decio as a ſubject, but Venice refuſed to part with him. In 1505, he removed to Pavia, where, for ſeven years, he explained the canon law to a numerous and very reſpectable audience. In a difference between pope Julius II. and the French, Decio took part with the latter, and was excommunicated; and what, perhaps, was a ſtill greater trouble to him, his houſe at Pavia was pillaged of every thing that was valuable by the Swiſs troops, who, not contented with this, went alſo to a monaſtery, the aſylum of Decio's natural daughter, and carried away the money that he had aſſigned for her ſubſiſtence. Decio had now no refuge but France; here he was greeted in every town, and received a full compenſation for his various loſſes. His lectures were crowded; and the king created him a member of the parliament of Grenoble. The pope would at this period willingly have been reconciled to him, on condition of his reſiding at Rome, which he thought fit to decline. His next ſituation was profeſſor of the civil law at Valence in Dauphinè, with a large ſalary. After various other changes, all honourable to the talents and virtues of Decio, he finiſhed his courſe at Piſa, at the age of 82. He was author of many works in his own profeſſion, which are of little note to the general reader. Gen. Biog.

DECIPHERING, or DECYPHERING, is the art of diſcovering and explaining what has been written in *cipher*. We have given a copious account of this art under the word CIPHER, and have illuſtrated our remarks by ſuitable examples. The authors who are moſt deſerving of notice on this ſubject are Mr. Falconer, Arnold Conrad, and Breithaupt; but the curious reader will alſo find a very methodical and complete ſpecimen of deciphering, in the 35th chapter of Graveſande's "Introductio ad Philoſophiam," printed at Leyden in 1737. No one plan of proceeding, however, can

can be applicable to different ſpecies of cipher; and, therefore, none of the above authors will be of much uſe in developing new and intricate modes of ſecret-writing. Dr. Wallis, the great mathematician, remarks very juſtly, that "all perſons are not qualified or capable of acquiring the art of deciphering, and that a certain degree of *acumen* is requiſite for this purpoſe."

DE'CISE, or DÉCIZE, in *Geography*, a ſmall town of France, in the department of the Nievre, and chief place of a canton, in the diſtrict of Nevers, on an iſland formed by the Loire, 178 miles S. by E. of Paris. It has 2212 inhabitants, and the canton, which has an extent of 352½ kiliometres, contains 17 communes, and a population of 9686 individuals. This place has an old caſtle, a priory, and two convents; it is ſeated on a rocky iſland near the conflux of the Airon and Loire, in *Bazois*, a diſtrict conſiſting of vallies lying along the hills of Morvan, and abounding in wood and paſturage; 8 leagues from Nevers, and 55 S.E. from Paris.

DECISIVE OATH, in *Civil Law*. See SACRAMENTUM *Deciſionis*.

DECIUS, MUS, P., in *Biography*, diſtinguiſhed for valour and patriotiſm, was a military tribune of plebeian rank in the army of C. Coſſus about the year B. C. 343, when it was brought into imminent danger of ruin by the Samnites. Decius ſaw a method of extricating his countrymen; he propoſed his plan to the general, which was agreed upon, and which, being inſtantly adopted, was crowned with complete ſucceſs. He was received by the general and ſoldiers as their deliverer, and was preſented, for his wiſdom and proweſs, with a golden crown, an hundred oxen, and a white bull, from the conſul: with an obſidional crown of graſs from the army, and a civic crown of oak from his own detachment. To himſelf he reſerved only the crowns, and diſtributed the other preſents among his brave comrades. Two years afterwards, he was created conſul with Manlius Torquatus. In a dangerous war with the Latins, it was agreed between the conſuls, that he whoſe army ſhould give way in battle ſhould devote himſelf to death for his country: the event took place in the ſucceeding combat, and Decius immediately plunged into the thickeſt part of the hoſtile forces, where he fell a ſacrifice to his patriotiſm: his body was found the next day buried under the enemy's weapons, and was honourably interred. Livy.

DECIUS, MUS, P., ſon of the preceding, was four times appointed conſul, and was, during his ſecond conſulate, B. C. 308, very ſucceſsful againſt the Etrurians. Five years afterwards he was elected cenſor with Q. Fabius Maximus, and in the following year he ſupported the claim of the plebeians to partake in the pontifical office, and was himſelf choſen into the college of pontiffs. With Fabius he again ſerved the office of conſul, when they obtained great and very important advantages over the Samnites and their allies. New dangers, to which the republic was expoſed from its confederated enemies, called forth the energy of Decius a fourth time as conſul. He was oppoſed by the Gauls, who, by means of their armed chariots, broke the Roman cavalry, and put the firſt line of infantry into the utmoſt confuſion. When Decius had done all to rally his troops without ſucceſs, he determined to imitate the patriotiſm of his father by a voluntary devotion of his life to his country's welfare. He called upon the pontiff to perform his part of the ceremony; to which Decius added the ſolemn prayer, "that he might carry before him terror and flight, blood and ſlaughter, the wrath of the celeſtial and infernal deities, and that the ſame ſpot might witneſs his own deſtruction, and that of the Gauls and Samnites." He then ruſhed into the midſt of the enemy, and was ſlain. By this act on the part of the conſul, the Romans were excited to new efforts, and the enemy were ſo confounded, that the victory was decided in favour of the republic. The names of the Decii have been held up to the world by the moſt celebrated poets of antiquity, for a patriotiſm and real worth never excelled, and rarely equalled. Rom. Hiſt.

DECIUS, emperor of Rome, was born in Pannonia, A. D. 201. We have no particular account of his origin; he probably was advanced to the rank of conſul for his ſuperior talents. By the emperor Philip he was ſent, much againſt his inclination, to command the legions in Mœſia and Pannonia, which had been guilty of revolt. Here, inſtead of purſuing the orders of his maſter, he aſſumed to himſelf the imperial title and dignity. He is ſaid to have been forced to this meaſure by the diſaffected troops. Philip, however, did not admit the excuſe, but immediately marched againſt the uſurper; they met near Verona, and a deſperate battle enſued, in which Philip was defeated, and killed either in the field, or put to death after he fell into the conqueror's power. This was in the year 249, which may be conſidered as the commencement of the reign of Decius. His eldeſt ſon he immediately raiſed to the rank of Cæſar. The reign of this emperor was very ſhort; but during the two years which it continued, he inflicted upon the Chriſtians the moſt cruel perſecutions, in which he omitted no means in his power to ſhake the faith of thoſe who had embraced the new religion. In other reſpects Decius obtained a good reputation: he diſtinguiſhed himſelf by an expedition againſt the Perſians. An invaſion of the Goths called forth all the energies of Decius; after much miſchief they ſued for peace, but Decius was deſirous of terminating the war by a blow: an action was commenced, and almoſt inſtantly the younger Decius was ſlain by an arrow: the father, who ſaw him fall, exclaimed, "be not diſcouraged, it is the loſs of one man only," and then ruſhed forward to revenge his death. He was, with the greater part of his troops, entangled in a moraſs, where ſurrounded by the enemy, he periſhed under a ſhower of darts. He died in 251, aged 50 years. Univ. Hiſt.

DECK *of a ſhip*, from *decker*, Dan. *to cover*; a kind of planked floor, connecting the ſides, and ſerving as different platforms to ſupport the artillery, to lodge the men, and to preſerve the cargo in merchant-veſſels.

A ſhip is ſaid to have two or three decks, when it contains two or three ſtories. Ships of the firſt and ſecond rates are furniſhed with three whole decks, reaching from the ſtem to the ſtern, beſides a fore-caſtle and a quarter-deck, which extend from the ſtern to the main-maſt. There is alſo another deck above the hinder part of the quarter-deck, called the poop, and ſerving as a roof for the captain's cabbin or couch. Inferior ſhips of the line of battle have two decks and a half; and frigates, ſloops, &c. have one gun-deck and a half; with a ſpare deck below to lodge the crew. The frame of the lower deck is ſtronger than that of the others, becauſe ſhips are broader at the lower deck than at the next above it, and it alſo bears the heavieſt cannon.

The decks are formed and ſuſtained by the beams, the clamps, the water-ways, the carlings, the ledges, the knees, and two rows of ſmall pillars called ſtanchions.

DECK, *Fluſh*, is one that lies even in a right line, fore and aft, from ſtem to ſtern.

The ſeamen ſay, a deck lies cambering, when it doth not lie level, but higher at the middle than at either end. A cambered deck is by no means proper for a man of war. Alſo if the ſhip's keel be bent in the middle upwards (which may happen from her lying aground on a place where neither her aft or fore part touch it, and from many other

other cauſes taken from her make), they ſay ſhe is camber-keeled.

Deck, *Half*, is a ſpace under the quarter-deck of a ſhip of war, between the foremoſt bulk-head of the ſteerage, and the fore part of the quarter-deck. In the Northumberland colliers, the ſteerage is called the half deck, and is uſually the habitation of the ſhip's crew.

Deck, a *Rope*, is that made of cordages interwoven, and ſtretched over a veſſel that has no deck, through which it is eaſy to annoy the enemy who comes to board her, and has leaped thereon. Theſe are little uſed but in merchant-veſſels, to defend them from the corſairs.

DECKED, or Marguette', in *Heraldry*, a term applied to an eagle or other birds, when their feathers are trimmed at the edges, with a ſmall line or purfle of another colour.

DECKENDORF, in *Geography*, a ſmall town of Bavaria, in lower Bavaria, in the diſtrict of the ſame name, with a bridge over the Danube.

DECKER, or Dekher, John, in *Biography*, was born in Flanders about the middle of the ſixteenth century. He was educated at Douay, from which place he removed to Rome, where he entered the order of the Jeſuits, and thence he went to Naples to complete his ſtudies, and to perfect himſelf in theology. As ſoon as he came back to Rome he took orders, and then went to his native place to teach philoſophy and ſcholaſtic theology. He was afterwards made chancellor of the univerſity of Gratz, in which ſituation he died in the year 1619. Decker is famous for his ſkill in chronology and hiſtory, and publiſhed various works chiefly in Latin, which exhibit much erudition and intenſe ſtudy: his chief work was entitled "Velificatio, ſeu theoremata de anno ortus ac mortis Domini, deque univerſa Jeſu Chriſti in carne economia, &c. cum tabula chronographica a capta par Pompeium Jeroſolyma ad deletam a Tito Urbem et Templum," 1616, 4to. Moreri.

Decker, Francis, a Dutch Phyſician and profeſſor in the practice of medicine at the univerſity of Leyden, who flouriſhed in the middle of the ſeventeenth century, was author of ſeveral works on different parts of medicine, which are ſtill occaſionally referred to; among them are "Exercitationes practicæ circa medendi methodum," Leid. 1673, 8vo. It has been ſeveral times reprinted. The medicines were firſt deſcribed, ranged in claſſes, with the compoſitions into which they enter; then the diſeaſes, with the method of treating them. In hæmoptœ the author frequently experienced good effects from the Dulcamara. He publiſhed an edition of the "Praxis Babettiana, with Notes and Obſervations," 1669, Leid. 8vo. In a mild apoplexy, he excited ſalivation by mercurial frictions with advantage. He does not ſay how long the frictions were continued before the effect was produced. In the ſame diſeaſe are recommended the reſin of colocynthis, and the extract of black hellebore, with more probability of ſucceſs. In lethargy he uſed the turbith mineral as an errhine. This is now uſed, and with advantage. Haller Bib. Med.

DECKINGEN, in *Geography*, a ſmall town of Wurtemberg, on the river Fils, in the diſtrict of Wieſenſteig.

DECLAMATION, a diſcourſe or ſpeech made in public, in the tone and manner of an oration.

Among the Greeks, declamation was the art of ſpeaking indifferently on all ſubjects, and on all ſides of a queſtion; of making a thing appear juſt that was unjuſt; and of triumphing over the beſt and ſoundeſt reaſons.

Such ſort of declamations, M. de St. Evremond obſerves, were only fit to corrupt the mind, by accuſtoming men, to cultivate their imagination rather than to form their judgment, and to ſeek for veriſimilitudes to impoſe upon rather than ſolid reaſons to convince the underſtanding.

It is ſaid that a certain orator, named Plotius Gallus, firſt introduced the uſe of declamations at Rome. In this way Cicero formed himſelf for eloquence. The term frequently occurs both in Horace and Juvenal.

Among us, declamation is reſtrained to certain exerciſes which ſcholars perform, to teach them to ſpeak in public.

We ſay, a declamation againſt Hannibal, againſt Pyrrhus, the declamation of Quintilian, &c.

In the colleges of the Jeſuits, declamations are little theatrical or dramatic performances, conſiſting of a few ſcenes not divided into acts, rehearſed by the ſtudents by way of exerciſe, and to form them for ſpeaking in public. Such declamations are the moſt uſeful exerciſes performed in the colleges.

Declamation, *Muſical*. See Recitative.

DECLAMATORY Style. See Style.

DECLANA, or Deciana, in *Ancient Geography*, a town of Spain, in the Tarragonenſis, and territory of the Endigatæ, according to Ptolemy, and the tables of Pentiager.

DECLARATION, in the *Cuſtom Houſe and Commerce of France*, contains a particular account or invoice of what is contained in the bales or caſes, brought to the officer for entrance inward or outward.

Declaration, in *Law*, called alſo *narratio* or *count* and anciently the *tale*, the act of ſhowing in writing the cauſe of complaint of the demandant, or plaintiff, againſt the defendant, where he is ſuppoſed to have received ſome wrong.

This is merely an amplification or expoſition of the original writ upon which the action of the plaintiff is founded, with the additional circumſtances of time and place, when and where the injury was committed. In the king's bench, when the defendant is brought into court by a Bill of *Middleſex*, upon a ſuppoſed treſpaſs, in order to give the court a juriſdiction, the plaintiff may declare in whatever action, or charge him with whatever injury he thinks proper; unleſs he has held him to bail by a ſpecial *ac etiam*, which the plaintiff is bound to purſue. And ſo alſo, in order to have the benefit of a *capias* to ſecure the defendant's perſon, it was the ancient practice, and is therefore ſtill warrantable in the common pleas, to ſue out a writ of treſpaſs, *quare clauſum fregit*, for breaking the plaintiff's cloſe, and when the defendant is once brought in upon this writ, the plaintiff declares in whatever action the nature of his true injury may require; as in an action of covenant, or on the caſe for breach of contract, or other leſs forcible tranſgreſſion; unleſs by holding the defendant to bail on a ſpecial *ac etiam*, he has bound himſelf to declare accordingly.

In *real* actions, when poſſeſſion of land is to be recovered, or damages for an actual treſpaſs, or for waſte, &c. affecting land, the plaintiff muſt lay his declaration, or declare his injury to have happened in the very county and place where it did really happen; but in *tranſitory* actions, for injuries that might have happened any where, as debt, detinue, ſlander, and the like, the plaintiff may declare in what county he pleaſes, and then the trial muſt be had in that county in which the declaration is laid. Though if the defendant will make affidavit, that the cauſe of action, if any, aroſe not in that but in another county, the court will direct a change of the *venue* or *viſne* (that is, the *vicinia*, or neighbourhood in which the injury is declared to be done), and will oblige the plaintiff to declare in the other county; unleſs he will undertake to give material evidence in the firſt. For the ſtatutes 6 Rich. II. c. 2. and 4 Hen. IV. c. 18. having ordered all writs to be laid in their proper counties, this, as the judges conceived, empowered them to change

the

the *venue*, if required, and not to inſiſt rigidly on abating the writ, which practice began in the reign of James I. And this power is diſcretionally exerciſed, ſo as to prevent and not to cauſe a defect of juſtice. Therefore the court will not change the *venue* to any of the four northern counties, previouſly to the ſpring circuit; becauſe there the aſſizes are holden only once a year, at the time of the ſummer circuit. And it will ſometimes remove the *venue* from the proper juriſdiction (eſpecially of a narrow and limited kind), upon a ſuggeſtion, duly ſupported, that a fair and impartial trial cannot be had therein. (Stra. 874.)

In actions upon the caſe, it is generally uſual to ſet forth ſeveral caſes by different counts in the ſame declaration; ſo that if the plaintiff fails in the proof of the one, he may ſucceed in another. And if he proves the caſe laid in one of his counts, though he fails in the reſt, he ſhall recover proportionable damages. This declaration always concludes with theſe words, "and thereupon he brings ſuit, &c." "*inde producit ſectam*, &c." But the actual production of the ſuit, the *ſecta*, or followers (*i. e.* the witneſſes) of the plaintiff), according to the ancient uſe of the term, is now antiquated; and hath been totally diſuſed, at leaſt ever ſince the reign of Edward III., though the form of it ſtill continues.

At the end of the declaration are added the plaintiff's common pledges of proſecution, John Doe and Richard Roe, which are now mere names of form, though formerly they were of uſe to anſwer to the king for the amercement of the plaintiff, in caſe he were nonſuited, barred of his action, or had a verdict and judgment againſt him. (3 Bulſtr. 275. 4 Inſt. 189.) For if the plaintiff neglects to deliver a declaration for two terms after the defendant appears, or is guilty of other delays or defaults againſt the rules of law, in any ſubſequent ſtage of the action, he is adjudged "not to follow" or purſue his remedy, as he ought to do; and thereupon a *nonſuit* or *non proſequitur* is entered; and he is ſaid to be *nonpros'd*. And for thus deſerting his complaint, after making a falſe claim or complaint *(pro falſo clamore ſuo)*, he ſhall not only pay coſts to the defendant, but is liable to be amerced to the king.

When the plaintiff hath ſtated his caſe in the declaration, it is incumbent on the defendant within a reaſonable time to make his defence (ſee DEFENCE), and to put in a plea (ſee PLEA); elſe the plaintff will at once recover judgment by *default*, or *nihil dicit* of the defendant. Blackſt. Com. b. iii.

In all notices of declarations, the cauſe ſhould be properly named, as well as the court in which the ſuit is inſtituted; and the nature of the action is alſo to be expreſſed, and at whoſe ſuit proſecuted; and the time limited to plead to ſuch declaration. R. T. 1 Geo. II.

On filing declarations, copies of them are ſerved on the defendants, or their attornies, &c. And by an order of all the judges, (12 W. III.) the plaintiff's attorney is not obliged to deliver the defendant's attorney the original declaration; but inſtead of it, is to deliver a true copy of the declaration; upon delivery or tender of which, the defendant's attorney ſhall pay for ſuch copy after the rate of 4*d.* per ſheet, &c.; and if any perſon refuſe to pay for the copy tendered, the ſaid copy is to be left in the office, with the clerk that keeps the files of declarations, and thereupon the plaintiff's attorney giving rule to plead, may, for want of a plea, ſign judgment; and before any plea ſhall be received, the defendant's attorney is to pay for the copy of the declaration. See alſo Trin. 2 Geo. II. There are ſeveral other rules of court as to the filing and delivering of declarations, &c. which may be found in the ſeveral books of practice. Jacob's Law Dict. by Tomlins, art. *Declaration*.

DECLARATION *of fidelity*, is uſed for a confeſſion, which the quakers, who ſcruple taking the oath of ſupremacy, &c. are obliged to make and ſubſcribe in lieu thereof.

Its tenor is a ſolemn promiſe to be true and faithful to king George; with a deteſtation and horror of that damnable poſition, that princes excommunicated by the pope, or any other power, may be depoſed or murdered; and a declaration that no foreign prince, or power, has any right, juriſdiction, or authority, in this kingdom.

There is alſo a declaration againſt tranſubſtantiation made and ſubſcribed by thoſe who qualify for offices; 25 Car. II. c. 2. and a declaration againſt popery to be made and ſubſcribed by the members of both houſes of parliament, by diſſenters qualified according to the toleration act, &c. &c. in which they renounce tranſubſtantiation, the invocation of ſaints and of the Virgin Mary, and the ſacrifice of the maſs, and every kind of evaſion, and mental reſervation, as well as diſpenſation or abſolution. 30 Car. II. ſtat. 2. c. 1.

DECLARATION of *War*, a public proclamation made by the herald at arms, to the members or ſubjects of a ſtate, declaring them to be at war with any foreign prince, and forbidding all of them to aſſiſt the common enemy at their peril.

DECLARATIONS, *Clerk of the*. See CLERK.

DECLARATORY *part of a Law*, is that by which the rights to be obſerved, and the wrongs to be avoided, are clearly defined and laid down. This depends not ſo much on the law of revelation or of nature, as on the wiſdom and will of the legiſlator. The rights which God and nature have eſtabliſhed, called natural rights, ſuch as life and liberty, receive no additional ſtrength when declared by the municipal laws to be inviolable. Indeed, no human legiſlature has power to abridge or deſtroy them, unleſs the owner himſelf ſhall commit ſome act that amounts to a forfeiture. Neither do divine or natural duties, ſuch as the worſhip of God, the maintenance of children, &c. receive any ſtronger ſanction from being alſo declared to be duties by the law of the land. The caſe is the ſame with regard to crimes and miſdemeanors, that are forbidden by ſuperior laws, and therefore ſtyled "mala in ſe," ſuch as murder, theft, perjury, which contract no additional turpitude from being declared unlawful by the inferior legiſlature. Upon the whole, the declaratory part of the municipal law has no force or operation at all, with regard to actions that are naturally or intrinſically right or wrong. But the caſe is entirely altered with reſpect to things that are in themſelves indifferent. Theſe become either right or wrong, juſt or unjuſt, duties or miſdemeanors, according as the municipal legiſlator ſees proper, for promoting the welfare of ſociety, and more effectually carrying on the purpoſes of civil life. Such are the declarations of common law, that the goods of the wife do inſtantly upon marriage become the property and right of the huſband; and the declaration of our ſtatute law, that all monopolies are a public offence. Thus alſo with regard to civil duties, obedience to ſuperiors is the doctrine of revealed as well as natural religion; but who thoſe ſuperiors ſhall be, and in what circumſtances, and to what degrees they ſhall be obeyed, it is the province of human laws to determine; and ſo, as to injuries or crimes, it muſt be left to our own legiſlature to decide, in which caſes the ſeizing of another's cattle ſhall amount to a treſpaſs or a theft; and where it ſhall be a juſtifiable action, as when a landlord takes them by way of diſtreſs for rent. Blackſt. Com. vol. i. Introd.

DECLARATORY *part of a Statute*, is that which relates to obſolete or diſputable cuſtoms: in which caſe the parliament has

has thought proper, *in perpetuum rei teſtimonium*, and for avoiding all doubts and difficulties, *to declare* what the common law is and ever hath been. Thus the ſtatute of treaſons, 25 Edw. III. c. 2. doth not make any new ſpecies of treaſon; but only, for the benefit of the ſubject, declares and enumerates thoſe ſeveral kinds of offence, which before were treaſon at the common law.

DECLENSION, in *Grammar*, the inflexion of a noun, according to its diverſe caſes. See CASE, NOMINATIVE, &c.

Mr. Harris obſerves, that the Peripatetics likened the noun in its primary and original form, to a perpendicular line; and the variations from the nominative were conſidered as if that line *fell* from its perpendicular to an oblique poſition: and hence the variations were called πτωσεις, *caſus*, *caſes*, or *fallings*. Grammarians were thus led to call the method of enumerating the various caſes of a noun κλισις, *declinatio*, *a declenſion*; becauſe it was a ſort of progreſſive deſcent from the noun's upright form, through its various declining forms. Hermes, p. 277. 278.

The declenſion of nouns is a different thing in the modern languages, which have not properly any caſes, from what it is in the ancient Greek and Latin, which have.

Declenſion in languages, wherein the nouns admit of changes, whether in the middle, beginning, or end, is properly the expreſſing or reciting all thoſe changes in a certain order, and by certain degrees, called *caſes*.

In languages wherein the nouns do not admit of changes in the ſame number, declenſion is the expreſſing of the different ſtates or habitudes a noun is in, and the different relations it has: which difference of relations is marked by particles called *articles*; as, *a*, *the*, *of*, *to*, *from*, &c.

DECLENSION *of a diſeaſe*, is when it is paſt its height, and the ſymptoms abate.

DECLINATION, *of a celeſtial object*, in *Aſtronomy*, is its angular or perpendicular diſtance from the equator, meaſured on a meridian or great circle paſſing through the object and the poles of the heavens.

A great circle paſſing in this manner through the poles, (and therefore perpendicular to the equator), is called a circle of declination.

Declination on the celeſtial globe, correſponds with latitude on the terreſtrial. And in the ſame manner as the geographical ſituation of a place is known, when its longitude and latitude are given, ſo in the heavens the place of a ſtar is determined, when its right aſcenſion and declination are known. To find, therefore, by obſervation the right aſcenſion and declination of a heavenly body is a problem of the firſt importance in practical aſtronomy. And moſt of the principal inſtruments in modern obſervatories are conſtructed with a view to one or other of theſe operations.

One of the moſt obvious methods of determining the declination of a ſtar is by means of its meridian altitude; for if this be given, and the latitude of the place known, the declination is eaſily calculated by the following rule:

When the latitude of the place and zenith diſtance of the ſtar are of different kinds, namely, one north, and the other ſouth, their difference will be the declination, and it is of the ſame kind as the latitude, when that is the greateſt of the two; otherwiſe it is of the contrary kind. If the latitude and zenith diſtance are of the ſame kind, *i. e.* both north or both ſouth, their ſum is the declination, and it is of the ſame kind as the latitude. But it will be found much more convenient to follow the method of many modern aſtronomers, who claſs the ſtars according to their north polar diſtance.

The declinations of all the celeſtial bodies are continually varying. To obſerve and explain the cauſe of theſe changes peculiarly belongs to the ſcience of aſtronomy.

The change of declination in the ſun ariſes from his motion in the ecliptic. When the obliquity of the ecliptic and the ſun's longitude are known, the declination is eaſily calculated by the ſolution of a right angled ſpherical triangle; or if the declination is obſerved, the ſun's longitude may be found by the ſame method. Twice a year, namely, at the equinoxes, the ſun has no declination; and twice a year, at the ſolſtices, his declination is the greateſt, being then equal to the obliquity of the ecliptic.

The declination of the moon varies in a ſimilar manner to that of the ſun, but more rapidly, as its revolution is performed in a ſhorter time. The ſame changes that are obſerved to take place in the declination of the ſun in the courſe of a year, occur to the moon in the ſpace of a month. Twice during this period the moon croſſes the equator, and therefore has no declination, and twice its declination is at a maximum. But the quantity of its greateſt declination, in one revolution, is exceedingly variable, being ſometimes equal to the *ſum* of the obliquity of the ecliptic, and the inclination of the moon's orbit to the ecliptic; at other times, only equal to the *difference* of theſe quantities. This is occaſioned by a retrograde motion of the moon's nodes, which ſucceſſively change their place throughout the ecliptic in the ſpace of about eighteen years.

The greateſt and leaſt declinations, both north and ſouth, happen when the nodes are in the equinoctial points. This will be eaſily underſtood by conſulting a celeſtial globe, or by referring to *Plate* V. *Aſtronomy*, *fig.* 44, where ♈ ♎ ♈′ repreſents the equator. When the aſcending node is in ♈, the moon's orbit lies above or without the ecliptic as ♈ *m* ♎ *n* ♈′ and its greateſt declinaton, *m p*, is equal to the obliquity of the ecliptic, plus *m c*, the inclination of the moon's orbit, her ſouthern declination, *p′ n*, is at the ſame time likewiſe a maximum; but when the deſcending node arrives at ♈ (by the retrograde motion above mentioned) the moon's orbit lies within the ecliptic, and its greateſt declination in the courſe of the month is *m′ p* and *p′ n′*, or the difference between the obliquity of the ecliptic and the inclination of the moon's orbit.

The declinations of the planets likewiſe vary from the intricate combinations of their reſpective motions with that of the earth. The declinations of the planets which are neareſt to us vary more rapidly, and with a greater apparent irregularity than thoſe more remote.

The changes that take place in the declinations of the fixed ſtars, are more uniform than any of thoſe above-mentioned, and ariſe principally from the retroceſſion of the equinoctial points. This motion, if uniform, would affect the longitude of every ſtar equally and uniformly, but the declination of a ſtar being its poſition relative to a different circle to that in which its motion in longitude is performed, the declination of ſome ſtars will be more affected by this retroceſſion than that of others. When the motion in longitude of a ſtar is nearly parallel to the equator, the declination is but little affected. This happens to thoſe ſtars which have 6 or 18 hours of right aſcenſion. The greateſt change takes place in thoſe ſtars which have 0 or 12 hours right aſcenſion.

Beſides this change of declination common to all ſtars, many of them have motions peculiar to themſelves. This is called their proper motion in declination: it is found by comparing obſervations made at very diſtant periods from each other. Theſe proper motions do not appear to follow any certain rule depending on their ſituation, yet Dr. Herſchel thinks many of them may be explained by ſuppoſing a

motion in the whole ſolar ſyſtem directed to a particular point in the heavens. The proper motion of each ſtar in declination is found by comparing its preſent place with that determined ſeveral years ſince: if its change in declination is only equal to that which ſhould take place from the calculated preceſſion, we preſume the ſtar to have no proper motion; but if any difference ſhould be found between its calculated and obſerved declination, and particularly if it exceed the probable errors of obſervation, then we ſuppoſe that difference to ariſe from the proper motion of the ſtar. We have annexed Dr. Bradley's catalogue of ſtars, obſerved about the year 1756, as they afford the moſt exact term of compariſon for modern obſervations.

The moſt ancient method of determining the declination of the ſun or moon, was by means of a gnomon or ſhadow; and till teleſcopes were applied to aſtronomical inſtruments, a more exact method could not eaſily have been deviſed.

Triangular or parallactic rules were uſed by Ptolemy, and the Arabian aſtronomers.

Mural quadrants have been employed in the moſt celebrated obſervatories of Europe for this purpoſe, till the late improvements in the conſtruction of aſtronomical circles have rendered it highly probable that the uſe of the quadrant will be entirely diſcontinued. For this reaſon, every thing here which relates to the practice of finding the declinations of celeſtial bodies, is intended only to apply to aſtronomical circles. The reader is referred to the article *quadrant*, for ſuch corrections as are peculiar to that inſtrument.

Armillary ſpheres were uſed by the ancients, and equatorial inſtruments, which bear ſome reſemblance to them, by the moderns, to obſerve the declinations of heavenly bodies, out of the meridian; but ſuch obſervations are only ſuited to accidental caſes, ſuch as for comets or planets when they cannot be ſeen on the meridian. All obſervations intended to ſerve as a foundation for aſtronomy ſhould be made when the object is on the meridian.

Method of obſerving Declinations with the aſtronomical Circle.

If the inſtrument is conſtructed with an azimuth circle, this ſhould be firſt placed in a horizontal poſition; this verification, though not abſolutely neceſſary, ſhould not be omitted. It is performed by bringing any one of the levels of the inſtrument into a line parallel with any two of the feet ſcrews, the bulb of the level being made to reſt in a central poſition; the inſtrument is next to be moved half round in azimuth, and if the level has changed its poſition, half the deviation is to be corrected by either of the feet ſcrews that are parallel to it, and the other half by any ſcrew that moſt conveniently acts on the level. The level muſt next be brought perpendicular to its firſt poſition, and the whole of its deviation corrected by the other foot-ſcrew.

The axis of the circle ſhould next be made horizontal. This is known to be accompliſhed, when the hanging level remains ſtationary during a whole revolution of the circle round its horizontal axis. Sometimes the level is not fixed to the axis, but only intended to be occaſionally applied to the pivots; in this caſe it muſt be reverſed end for end, and if the bulb of the level reſts at the ſame point in each poſition, the axis is horizontal.

The poſition of the micrometer wire ſhould now be examined, a diſtinct object ſhould be biſected, and the whole inſtrument moved gently in azimuth by the tangent-ſcrew of the azimuth circle. The object ſhould remain biſected in every part of its apparent motion through the field of the teleſcope; if it does not, the micrometer muſt be moved in its cell till this is effected. When the circle does not move in azimuth, this verification may be performed by the vertical wire, taking for granted that the horizontal wire is at right angles to it, or it may be examined, by obſerving if a ſtar in the equator continues biſected during its paſſage through the field of the teleſcope.

The line of collimation ſhould next be made to deſcribe a great circle of the ſphere. This is done when the inſtrument admits of it by reverſing the circle in its Y's, and obſerving if the ſame object is biſected in each poſition; when this cannot be done, the inſtrument muſt be turned half round in azimuth; by this means the line of collimation is rendered perpendicular to the horizontal axis.

We will now ſuppoſe that the mechanical adjuſtments have been accurately performed, and the inſtrument placed in the meridian, and that the object of the obſerver is to undertake a courſe of obſervations for the purpoſe of determining the declinations of the fixed ſtars, and other celeſtial objects.

Some time before the ſtar is expected on the meridian, the teleſcope ſhould be directed nearly to the place of the ſtar, ſo that it may paſs through the field; this may eaſily be done, as the latitude of the place is always ſuppoſed known within a few minutes. The plumb-line point ſhould be accurately biſected, and the inſtrument carefully protected from the ſun, and from unequal currents of air. Solar obſervations ſhould always be omitted, where they do not form an eſſential part of the object of inveſtigation, as they have a great tendency to derange ſome of the nicer adjuſtments of theſe inſtruments.

As ſoon as the ſtar appears in the teleſcope, it ſhould be brought to the middle wire by the micrometer ſcrew, which gives motion to the whole inſtrument. The plumb line ſhould now be again examined, and the biſection of its dot or point made with all imaginable preciſion; the ſtar will now probably be very near the middle wire, and ſhould be biſected by the micrometer-ſcrew; and in effecting this, great care ſhould be taken to avoid all undue preſſure either forward or ſideways, which might derange the plumb line. The preſſure of the finger and thumb ſhould be wholly directed towards the centre of the head of the ſcrew. The ſtar and the plumb-line ſhould be alternately examined; and when both remain ſteadily biſected, the obſervation may be conſidered as good. If the ſtar is near the equator, it will continue biſected for ſome time; but if its declination be conſiderable, it is eſſential to accompliſh the biſection near the middle wire. The obſervation ſhould be immediately read off at each microſcope, and the ſame precaution ſhould be obſerved in the management of their ſcrews, as was recommended above in the uſe of the micrometer-ſcrew.

With tranſit circles, not fixed on ſtone-piers but on frame work, ſuch as deſcribed by Mr. Wollaſton, vide CIRCLE, and Ph. Tranſ.; this method of biſecting the plumb-line point, and the ſtar, at the ſame inſtant, cannot be adopted; and ſo much muſt depend on the ſtability of every part of the inſtrument, that it is not much to be wondered at that theſe inſtruments have not been very ſucceſsful.

The ſtate of the barometer and thermometer (the latter within the tube of the teleſcope, if poſſible) ſhould be noted down.

It is eaſy to ſee that by this obſervation alone, the obſerver can derive no information either with reſpect to the declination of the ſtar or the latitude of the place. But if, on the ſame night, an obſervation can be obtained of the pole ſtar, or any other circumpolar ſtar, both above and below the pole, the polar diſtance of any other ſtar may be deduced by a direct compariſon, without any reference to the real altitude or zenith diſtance of either of them, provided the altitude is known near enough for the purpoſe of calculating the refrac-

tions.

tions. And here it may be remarked, that if the inſtrument does not turn freely in azimuth, this mode of obſerving polar diſtances, by reference to the polar point on the inſtrument, will be found very convenient in practice, and often preferable to the uſual mode of ſuppoſing the true zenith diſtance and latitude known. But if the inſtrument revolves freely in azimuth, then having obſerved ſeveral ſtars, in the manner above deſcribed, the inſtrument ſhould be turned half round in azimuth, and the plumb-line point biſected. The circle ſhould on no account be handled more than is abſolutely requiſite for this operation. The ſame ſtars that were obſerved in the firſt poſition ſhould now be obſerved again in preciſely the ſame manner, but the microſcopes will not indicate the ſame quantities. If in the firſt poſition they gave zenith diſtances, they will now give altitudes; or, if one miſcroſcope is made to mark the zenith diſtance, and the other the altitude, they will be now reverſed, and the one which gave zenith-diſtance will now give altitude. When the ſtars have been thus obſerved two or three times in each poſition, the obſerver will be enabled to judge both of the perfection of his inſtrument, and of his own ſkill in the management of it. For in calculating the above obſervations, he ſhould begin by deducing the index error, or error of collimation, from each ſtar ſeparately; and the difference of the quantities thus found ſhould, if the inſtrument and obſervations are good, be contained in very narrow limits.

Half the extreme difference will be very nearly the greateſt error to which the obſervations will be liable.

Upon this ſubject, vid. Ph. Tranſ. 1806.

To illuſtrate this, we ſhall take for example ſome obſervations made with an aſtronomical circle of two feet diameter, conſtructed by Mr. Troughton, and which moved freely in azimuth.

Mean Error of Collimation	39. 0	

From this it ſhould appear that 3″ was probably the greateſt error committed in the determination of the altitudes of the above ſtars, including errors of every kind. Had the obſervations been continued, the diſcordance would have been leſs, as the errors of obſervation would have been gradually done away, and the errors of diviſion only would have remained.

The index error being thus found, may be applied to any ſtar or planet that has been obſerved only in one poſition of the inſtrument. A well divided circle of two feet diameter will, in the hands of a careful obſerver, always give declinations true to 2″ or 3″.

The zenith diſtances being brought up to the beginning of the year, ſhould be regiſtered in a table. The polar diſtance is obtained by applying the co.-lat. of the place of obſervation; but this ſhould be conſidered as an equation known at firſt only as an approximation to the truth. Many months may elapſe before an obſerver, who is anxious to attain perfection, will be ſatisfied with the accuracy of this eſſential element in his calculations. In uſing large inſtruments on ſtone piers, which cannot be reverſed without great danger of diſturbing their adjuſtments, the method of finding the Polar-point on the circle, and referring all obſervations to it, is preferable to the other; and here the obſerver muſt be as ſcrupulous in his attention to aſcertain this point accurately, as to find the latitude in the uſual method. Obſervations of circum-polar ſtars are in each caſe to be ſelected for the purpoſe.

Of the Corrections to be applied to the Obſervations.

Theſe are of two kinds, one depending on the mechanical conſtruction of the inſtruments, the other entirely aſtronomical, and intended to reduce the apparent altitude as ſeen at the place of the obſerver, to that which would have been obſerved from ſome other ſituation, as the centre of the earth; or even at ſome other period, as the beginning of the year.

The corrections ariſing from the conſtruction of aſtronomical circles are very few, as theſe inſtruments have the means of avoiding moſt of the deviations that quadrants are ſubject to. The index error, as above deſcribed, is the principal correction in ſingle obſervations; and half the thickneſs of the wire of the micrometer ſhould be taken into the calculation, where one of its edges has been made a tangent to the upper or lower limb of the ſun, moon, or planet. But when the micrometer is formed by fine cobweb, this method need not be adopted.

The corrections for reducing the apparent zen. diſt. at the time of obſervation, to the true zen. diſt. as ſeen from the centre of earth, for the beginning of the year, ariſe from refraction, parallax, aberration, nutation, preceſſion, and ſemi-annual ſolar-equation. For an explanation of theſe corrections, ſee the reſpective articles ABERRATION, NUTATION, &c. &c.

Among the tables ſubjoined will be found thoſe of the Rev. Mr. Wollaſton, which are much the moſt convenient of any that have yet been publiſhed for reducing obſervations of this kind. By means of theſe tables the obſerver will be enabled, with the greateſt eaſe, to regiſter all his obſervations, with their reſpective corrections, in one column, which will greatly facilitate all the ſubſequent calculations.

It ſometimes will happen, that an obſervation cannot be taken, at the preciſe moment the ſtar is on the meridian, but a few minutes before or after. If the inſtrument moves in azimuth, it ſhould be made to follow the ſtar; and if the ſtar is on the middle of the field, when the obſervation is made, no other correction is required than for the change of altitude in the ſtar, for the given interval, which will be found in the tables for the uſe of the French repeating circle. But in a fixed inſtrument, the only obſervation that can be had, may be when the ſtar has conſiderably paſſed the centre of the field, in this caſe a double correction muſt be applied. The firſt to reduce the obſerved altitude, to that which would have been given by the inſtrument, if the ſtar had been obſerved on the vertical wire; the ſecond is the ſame as above mentioned, namely, to allow for the change of altitude in the ſtar ſince the moment of its tranſit over the meridian. The firſt correction is given in Tab. XXI. The argument on the left hand column is the altitude, and on the top the diſt. from the vertical wire.

To obſerve the Declination of the Sun.

This obſervation requires the following corrections: error of collimation, refraction, parallax, ſemidiameter of the ſun, and for half the thickneſs of the micrometer wire, when it is made a tangent to the limb of the ſun. Theſe quantities are eaſily taken from the annexed tables. The ſemidiameter of the ſun will vary according to the power of the teleſcope, ſo that it is adviſeable to obſerve ſometimes the upper, and ſometimes the lower limb. If the circle is of ſmall dimenſions, and turns eaſily in azimuth, two or more obſervations may be obtained in one day, an allowance being made for the ſun's motion in altitude, according to ſuch rules as will be given when we come to treat more particularly of the French repeating circle. In obſerving the ſun, the inſtrument ſhould be carefully protected from its rays till the moment of obſervation.

Example of an Obſervation of the Sun, made at Weſtbury in Somerſetſhire, with a circular Inſtrument conſtructed by Mr. Troughton.

The mean of theſe two obſervations will give the declination of the ⊙ at the intermediate midnight very accurately = 23° 28′ 3″.

The

The corrections to be applied to the obſervation of the meridian altitude of a fixed ſtar to find its mean declination at the beginning of the year, are thoſe depending on refraction, preceſſion, aberration, nutation, and ſemi-annual ſolar equation.

When it is intended to obſerve the ſame ſtars frequently, it will be found very convenient to make a table of their mean refractions, with the change for each degree of the thermometer, and for each tenth of an inch of the barometer, as given in Mr. Wollaſton's tables, which are here ſubjoined.

When the meridian altitude or zen. diſtance of a planet is obſerved: the calculation for finding its declination differs but little from that of a fixed ſtar, except that the correction for parallax and a b ration muſt be taken from the tables of the planet. If one of the principal fixed ſtars paſſes nearly at the ſame time, differing but little in altitude, the declination of the planet had better be calculated by comparing it with the fixed ſtar.

Obſervations made to determine the declination of the moon require ſome corrections that ſhould be particularly explained. It is uſual to obſerve either the upper or lower limb. If we wiſh to know what would have been the *obſerved* altitude of the centre, we muſt employ the ſemidiameter augmented according to its altitude, and diminiſhed by the difference of refraction correſponding to the limb and the centre; or, we may proceed to calculate the declination of the obſerved limb. This latter method we think preferable to the other.

The correction for parallax varies according to the altitude of the moon, and is ſubject to a ſmall equation depending on the latitude of the place, as will be more fully explained under PARALLAX: enough for the preſent purpoſe will be underſtood by referring to *Plate* V. *fig.* 45.

O repreſents the place of the obſerver, on the elliptic meridian, E P Q *p*. O *m*, the normal or continuation of the direction of the plumb-line; *Z*, the zenith; H *h*, or H′ *h*′, the horizon; the angle obſerved is M O Z, or its compl. M O H′. The declination of the lower limb required is the angle M C E. If the moon were in the line Z O, it would have no parallax, and its zenith diſtance would equal the angle which the vertical, O *m*, makes with the radius. If the moon were in the zenith Z, it would nevertheleſs have a ſmall parallax.

The equatorial parallax muſt be diminiſhed in the proportion of E C to O C.

Example, taken from the Greenwich Obſervations.

Sept. 1. 1806. The zenith diſtance of the moon's upper limb was obſerved 38° 48′ 32″.3. The error of collimation was 2″.9, and the error of the arc, (vide note to obſervations) was 1″ additive. The refraction was 45″.1.

Theſe corrections make the zenith diſtance 38° 49′ 21″.3.

The equatorial parallax by the tables was at that time 55′ 30″; this diminiſhed in the proportion of E C to O C (by Table XX.) is 55′ 24″, which is the horizontal parallax at Greenwich: this multiplied by the ſine of the zenith diſtance *minus* the angle which the radius makes with the vertical, or the angle C O *m* = 10′ 3″ (Tab. XX.) gives 34′ 36″.2 for the parallax in alt. which is to be ſubtracted from the zenith diſtance, and leaves 38° 14′ 45″.1.

The ſame tables which give the equatorial parallax 55′ 30″, give the ſemidiameter 15′ 8″.8, which added to the zenith diſtance of the upper limb gives the zenith diſtance of the centre 38° 29′ 54″; and this taken from the latitude, leaves for the declination of the moon at the moment of obſervation 12ʰ 58′ 46″.

On the Method of determining the Declinations of the Stars by Means of the repeating Circle.

It has been observed under the article *Circle*, that this instrument has not yet been received into such general use in this country as on the continent, where it has almost superseded every other of the kind. With us it is but little known, though brought to the greatest perfection by one of our first artists. Perhaps we have received an unfavourable impression of it from the accounts originally transmitted to us by the French astronomers themselves, from which we were led to suppose that it was merely an ingenious contrivance to obviate the errors of a very imperfect instrument. Even in this point of view it would possess great merit; but though it certainly derives its great superiority from its property of repeating the angle; it is so far from being imperfect as an instrument for single observations, that it is equal, and perhaps superior, to any instrument of its size now in use.

If the plane of the instrument be placed in the meridian, and the level retained in a given position by means of a contrivance which Mr. Troughton has applied to some of these circles, the instrument will then very much resemble, in its principle and mode of acting, the great circle which is now constructing for the Observatory at Greenwich, and with this additional advantage that its face may be turned either to the east or west, and as the position of the circle may be changed with respect to the level, the same stars may be observed on a new set of divisions, and the four verniers are much superior in accuracy to the two microscopes which are usually applied to instruments of the other construction. The English circles which we have described are at the same time, altitude, azimuth, and transit instruments, and are so well contrived to answer these several purposes, that no sacrifice has been made in the accuracy of one operation to enable them to perform the others. The repeating circle has no such pretensions, its use as an astronomical instrument is confined to the determination of zenith distance only.

Verification of the repeating Circle.

1. To make the axis of vision of the telescope parallel to the plane of the circle.

Choose for this purpose a very distant terrestrial object, or the pole star, when at its greatest elongation from the meridian, then with the plane of the circle in a vertical position, bisect the object or star with the vertical wire, and observe what is marked by the vernier on the azimuth circle. Turn the circle exactly half round in azimuth, and the telescope half round on the circle, and if the same object is bisected, the adjustment is already perfect; if not, half the error or deviation must be rectified by the screws that act on the micrometer wires, and the other half by the tangent screw of the azimuth circle.

2. To place the plane of the circle in a true vertical position.

This adjustment is very essential when zenith distances are intended to be taken with the greatest possible precision. There is usually a mark on the small semicircle made for this purpose by the maker, the coincidence of which with a line marked on the pedestal, indicates that the plane of the vertical circle is at right angles to the azimuth circle; so that if the latter be properly adjusted, the former may be brought by this mark to its true position. This verification may likewise be accomplished by suspending a plumb line on the back of the instrument. But a much more accurate method is by means of a level properly adapted to the back of the circle. This level may be adjusted and examined in the following manner:

Select an object of considerable altitude, as a steeple or neighbouring chimney, observe some well-defined part in it, both directly and by reflection in a saucer, of oil or treacle. If the same object be intersected accurately by the vertical wire in both cases, the plane of the circle will be very exactly vertical, and the level may be then adjusted, and should be occasionally examined by the same method.

To place the horizontal wire in its proper position, so that it may be parallel to the horizon when the circle is vertical, adjust the azimuth circle, and bring the repeating circle to its vertical position; bisect some well defined horizontal

zontal object at the extremity of the wire, move the object along the field of view by means of the tangent-ſcrew to the azimuth circle, and obſerve if it remain continually biſected till it arrives at the other extremity; if it does not, turn round the wires in their cell, till this verification is obtained.

Verification of the Verniers.

Call the vernier which is connected with the clamp-ſcrew No. 1, the others No. 2, No. 3, No. 4, in ſucceſſion, according to the diviſions of the circle. Place No. 1. at Zero, read off all the others, and ſet down their deviations with the ſign + or −, as they exceed or fall ſhort of their reſpective diviſions, add theſe quantities, and divide the ſum by 4. This quotient may be called the index error, and muſt be applied to the obſerved angle with a contrary ſign. *e. g.*

No. 1. . .	00″
2. . .	+05
3. . .	+10
4. . .	− 3
	4) +12
	+ 3″ Index error to be

ſubtracted from the obſerved angle: then ſuppoſe at the end of an obſervation the verniers ſtand thus:

No. 1. .	183°	14′	10″
2. .			7
3. .			14
4. .			20
			4) 51
	183	14	12.77
Deduct Index error		—	3
True Angle .	183	14	9.77

The obſerver ſhould take notice, that the circle, the level, and the front teleſcope, all turn round one common axis, independent of each other. Now, in obſerving, it muſt be remembered, that the circle muſt always be fixed to, and form one piece with one of the other two. In the front obſervation which begins the ſeries, it muſt be conſidered as forming one piece with the front teleſcope, and care muſt be taken on no account to touch the ſcrew that alters their relative poſition to each other. On the contrary, in the reverſe obſervation, the circle muſt be conſidered as forming one piece with the level, and equal care taken not to ſeparate them from their fixed poſition. The great danger to an unexperienced obſerver with this inſtrument is, that his whole ſeries of obſervations may be deſtroyed by improperly releaſing the piece which ought to remain fixed.

But a little conſideration and practice will render this operation eaſy and familiar.

A well regulated clock or watch is neceſſary for theſe obſervations; and they will be rendered much eaſier, if an aſſiſtant attends to the level, while the obſerver biſects the ſtar.

It may not be improper to remark, that it is of more importance to make good, than many obſervations. The errors of diviſion are ſo ſmall in our beſt conſtructed inſtruments, that a very few repetitions will render their effect quite inſenſible. The obſerver will ſoon find that it is the error of obſervation he has to contend with, ariſing from the ſmallneſs of the radius, and want of power in the teleſcope; for this reaſon, the obſervations ſhould not be hurried, but ſufficient time allowed for examining the true poſition of the level and the accurate biſection of the ſtar.

The corrections to be applied to the obſervations made with the repeating circle are, for the purpoſe of reducing the meridian altitude, from that obſerved a ſhort time before or after the paſſage of the ſtar over the meridian. The hour angle, or diſtance of the ſtar from the meridian, muſt, therefore, be correctly known; and in proportion as the rate of the clock is well aſcertained, may the obſervations be extended with confidence on each ſide of the meridian.

The pole-ſtar, from the ſlowneſs of its motion, being the beſt adapted for obſervation with this inſtrument, we have given a table of corrections for that particular ſtar, extending to half an hour from the meridian, beyond which the obſervations ſhould never extend. This table having been calculated for the latitude of Paris ſome years ſince, the numbers muſt now for the latitude of Greenwich be diminiſhed $\frac{1}{20}$th, that is, the whole correction multiplied by 0.95; and for the inferior paſſage of the ſtar the whole correction muſt be multiplied by 0.88.

Tables II. and III. are general tables for any ſtar, and for any latitude; they were calculated by Delambre from the following formula:

Let P = The hour angle,
L = Latitude,
D = Declination of the ſtar.
x = Corrections required.

If the ſtar paſs ſouthward of the zenith $x = -\frac{2 \text{ ſin.}^2 \frac{1}{2} P, \text{ cof. D, cof. L}}{\text{ſin. (L} - \text{D) ſin. 1}''} + \frac{1}{2}\left(\frac{2 \text{ ſin.}^4 \frac{1}{2} P, \text{ cof. D, cof. L}}{\text{ſin. L} - \text{D ſin. 1}''}\right)^2 \text{cof. L} - \text{D ſin. 1}''$.

If the dec. be ſouth, change the ſign of D.

If the ſtar paſſes to the north of the zenith, for L − D ſubſtitute D − L, and change the ſign of the terms.

But if the ſtar paſſes below the pole, D + L muſt be ſubſtituted for D − L, the ſigns remaining the ſame.

The numbers contained in theſe tables are the factors $\frac{2 \text{ ſin.}^2 \frac{1}{2} P}{\text{ſin. 1}''}$, and $\frac{2 \text{ ſin.}^4 \frac{1}{2} P}{\text{ſin. 1}''}$, the remainder of the calculation is thus reduced to finding the value of the other factors, $\left(\frac{\text{cof. D, cof. L}}{\text{ſin. D} - \text{L}}\right) = \text{F}$, and $\left(\frac{\text{cof. D, cof. L}}{\text{ſin. D} - \text{L}}\right) \text{cof. D} - \text{L} = f$.

Example of an Obſervation of the Pole Star, by the repeating Circle. Dec. 4th, 1807.

DECLINATION.

Dr. BRADLEY's CATALOGUE OF FIXED STARS.

THOSE ſtars whoſe right aſcenſion is between 90° and 270° with north declination, and more than 270° and leſs than 90° with ſouth declination, have their annual variation of declination *ſubtractive*; and thoſe ſtars whoſe right aſcenſion is more than 270° and leſs than 90° with north declination, and between 90° and 270° with ſouth declination, have their annual variation of declination *additive*. This is to be underſtood with reſpect to a time *after* January 1, 1760; but, if the time *precede* that period, the variation of declination is to be applied with a *contrary* ſign.

TABLE II.

CORRECTIONS of R. A. in Time of the STARS in the preceding Catalogue to every Tenth Day in the Year: Copied exactly from Dr. MASKELYNE's; excepting α Herculis, which has been added.

N. B. In this Table an allowance is made for the Motion of each Star as set down at the bottom of its Column.

DECLINATION.

The following Tables are calculated to give the Corrections in N. P. D. for the Stars of Dr. Maſkelyne's Catalogue, as the foregoing, copied from his Tables XVII. and XVIII. do in R. A.

Table IV. compriſes the effects of præceſſion, aberration, and the ſolar inequality for every 10th day of the year.

Table V. compriſes the effect of nutation, for every 10th degree of longitude of the moon's node.

They neither of them contain any allowance for the motions in the ſtars themſelves; which ſeem, as yet, not to be ſufficiently aſcertained.

Theſe Tables are adapted to the year 1800; but the differences are inconſiderable, for many years before and after that period.

TABLE IV.

CORRECTIONS in N. P. D. for every 10th Day of the Year.

Minutes. Minutes.

The number of ſeconds and their decimals taken out of this Table being multiplied by the natural tangent of the ſtar's declination, and applied with their reſpective ſign to + 3″ 068 will give the annual præceſſion in R. A.

If the ſtar's declination be ſouth, the number ſo found muſt be applied with a contrary ſign.

TABLE VIII.

Decimal Numbers for multiplying the Annual Præceſſion of a Star in R. A. with their Complements.

			29	.66	.34	31	1.00	.00

These Tables are intended for deducing the apparent R. A. and N. P. D. of a Star from its mean position; and the signs ± are set down accordingly. If the mean position is to be deduced from an observed or apparent place, the numbers must of course be applied with a contrary sign.

The mean R. A. and N. P. D. of a Star, being brought up to the day in question, by the respective annual præcessions multiplied by the Tables VIII. and X. its apparent R. A. for that day may be deduced by Tables XI. XII. and XIII. and its apparent N. P. D. by the Tables XIV. XV. XVI. and XVII.

TABLE XI.

For finding the Effect of Aberration on R. A. in Time, for every 10th Day of the Year, and each Hour of the *'s R. A.
These Numbers must be multiplied by the nat. secant of the *'s Declination.

Table XII.

For finding the Effect of Nutation in R. A. in Time for every 10° of ☽'s ☊, and each Hour of ✳'s R. A.
These Numbers must be multiplied by the Natural Tangent of the ✳'s Declination, which will be Negative, if the Declination be South.

Explanation of the Tables.

I. That which claims a decided preference before all others, is a catalogue of 36 principal ſtars viſible in the northern hemiſphere, deduced from the obſervations of Dr. Maſkelyne.

II. A table of the corrections of RA in time for the ſtars in the preceding catalogue, to every tenth day of the year; copied exactly from Dr. Maſkelyne's, and printed by his permiſſion. This table contains the ſum of the preceſſion from the beginning of the year, aberration, and ſolar inequality of preceſſion; together with an allowance for the motions of ſome of the ſtars, the quantity of which allowance to each ſtar will be found in this copy at the bottom of its reſpective column. To this table, a column for α Herculis has been added in its place by the author.

III. A table of the corrections of RA in time for the ſame ſtars, to every 10th degree of longitude of the moon's node; compriſing the effect of nutation and the equation of the equinoxes.

IV. and V. are two ſimilar tables of the corrections of NPD for the ſame ſtars. The firſt compriſing the effects of preceſſion, aberration, and ſolar inequality, for every 10th day in the year. The ſecond, the effect of nutation for every 10th degree of longitude of the moon's node.

Theſe two, neither of them, contain any allowance for the motions in the ſtars themſelves; which ſeemed not to be ſufficiently aſcertained at the time theſe tables were conſtructed.

VI. A table of the mean RA and NPD of polaris for Jan. 0. 1800, and 10 years following; together with the corrections both in RA and NPD for every 10th day of the year, and every 10th degree of longitude of the moon's node.

Theſe new tables were calculated for the year 1800. Numbers IV. and V. will ſerve for many years before and after that epoch. Number VI. cannot long continue ſo correct; becauſe of the rapid annual increaſe of preceſſion in RA and decreaſe in NPD in that ſtar. But if its mean RA be brought up carefully to the beginning of a year, the numbers in the firſt part will ſcarcely err $1''$ at the utmoſt in RA; nor thoſe in the column for NPD $0''.01$; from the truth, if the table be rightly conſtructed.

Numbers VII. VIII. IX. and X. are copied from Dr. Maſkelyne; for finding the annual preceſſion of a ſtar in RA and NPD, with their reſpective multipliers. The only alteration that has been made in theſe is in Number VII. and IX. where the argument, the RA of the ſtar, is altered from the RA in degrees, &c. to RA in time; and a mean interpolation has been introduced between the numbers given by the aſtronomer royal.

Next follows a ſet of general tables, computed by the author on the plan of the foregoing; for deducing the apparent RA and NPD of any ſtar in any part of the heavens from its mean poſition; or, *vice verſâ*, by applying the numbers taken out of the tables with a contrary ſign, for deducing the mean poſition of any ſtar from its obſerved or apparent ſituation; *viz.*

Table XI. for finding the effect of aberration on a ſtar's RA in time, for every 10th day of the year, and each hour of the ſtar's RA.

Table XII. for finding the effect of nutation on the ſtar's RA in time, for every 10th degree of longitude of the moon's node, and each hour of the ſtar's RA.

Table XII. the equations of the equinoxes in RA in time, copied from Dr. Maſkelyne.

Theſe all relate to the RA of the ſtar, and its neceſſary corrections. The following give the corrections for NPD:

Table XIV. for finding the effect of aberration on the NPD of a ſtar, for every 10th day of the year, and each hour of the ſtar's RA.

Table XV. for finding the farther effect of aberration, for every 10th day, according to the declination of the ſtar.

Table XVI. for finding the ſemi-annual ſolar equation in NPD, for every 10th day, and each hour of the ſtar's RA.

Table XVII. for finding the effect of nutation on the NPD of the ſtar, for every 10th degree of longitude of the moon's node, and each hour of the ſtar's RA.

It is hoped theſe tables will be found as convenient to the practical aſtronomer as they have been to the author, who compiled them merely for his own uſe. He publiſhes them with diffidence; but flatters himſelf that they are not liable to many errors, at leaſt he does not feel conſcious of any which it was in his power to avoid.

The above tables were publiſhed by the Rev. Mr. Wollaſton in his faſciculus of aſtronomical obſervations: he has been ſo obliging as to comply with our requeſt to reprint them in this work. They are admirably calculated to diminiſh the labour of reducing obſervations of right aſcenſion and declination, and will no doubt be conſidered as a valuable acquiſition by the practical aſtronomer.

Table XVIII. contains the mean refractions to every 10 minutes of zenith diſtance, as derived from the obſervations of Dr. Bradley: it is taken from the Greenwich obſervations of 1797, as there given by the aſtronomer royal.

Table XIX. is the augmentation of the ſemi-diameter of the moon, requiring no explanation.

Table XX. is the diminution of the horizontal parallax of the moon, ariſing from the ſpheroidal figure of the earth: the ellipticity is here ſuppoſed $\frac{1}{334}$, according to the lateſt determinations of the figure of the earth.

Table XXI. contains the correction to be applied to an obſervation with a fixed inſtrument, when the ſtar has paſſed or not arrived at the vertical wire, to reduce it to that which would

would have been given *at the ſame moment* by the centre of the wires.

The three tables which follow are to facilitate the uſe of the repeating circle. They give the correction to be applied to an obſervation made at a given interval of time from the tranſit of a ſtar over the meridian.

The firſt table is calculated for the pole ſtar only.

This table having been calculated ſome years ſince for the latitude of Paris, theſe numbers muſt now be multiplied by 0.95 for the ſuperior tranſit, and by 0.88 for the inferior.

The uſe of the general Tables II. and III. has been explained in the text.

The above tables contain all the corrections that occur in obſervations for determining the declinations and right aſcenſions of the heavenly bodies, except ſuch as relate to the mechanical conſtruction of the tranſit inſtrument, which will be found under that article. But as ſome doubts are entertained relative to Dr. Bradley's refractions, we ſhall annex a comparative table of refractions, as derived from the obſervations of different aſtronomers, as given in the third vol. of Mr. Vince's Aſtronomy.

A Table of Refraction, according to different Authors. The Barometer $0^m.760$.

DECLINATION.

Declination, *Circle of*, is a great circle of the ſphere paſſing through the poles of the world; and on which the declination of a ſtar is meaſured. See Declination, in *Aſtronomy*.

Declination, *Parallax of*, is an arc of the circle of declination, whereby the parallax of the altitude increaſes or diminiſhes the declination of a ſtar.

Declination, *Refraction of the*, an arc of the circle of declination, whereby the declination of a ſtar is increaſed or diminiſhed by means of the refraction.

Declination, from the Latin *declinatio*, in a general ſenſe, means the variation from a fixed point. The *declination of the magnetic needle*, or of the mariner's compaſs, is its variation from the true meridian of the place; for it hardly ever happens at any time in any place, that the magnetic needle points due north and ſouth; or that the magnetic meridian coincides with the aſtronomical meridian of the place. The quantity of this declination is uſually meaſured by an arc of the horizon, or of an horizontal circle, intercepted between the true north point of the horizon, and the north extremity of the magnetic needle. Thus, when the declination is ſaid to be twenty degrees weſt, the meaning is, that if a ſtraight line be drawn through the centre, or point of ſuſpenſion, of the needle, and through the true north point of the horizon, then the north half of the needle lies on the weſt of that line, and makes an angle of 20 degrees with it. If the declination is ſaid to be 12° eaſt, the meaning is, that the north half of the magnetic needle lies on the eaſt ſide of the line which paſſes through its centre and the true north point of the horizon, making an angle of 12° with it. It is evident that when the north half of the needle lies on the eaſt of the above-mentioned line, which, in fact, is the meridian of the place; the other half of the needle muſt lie on the oppoſite, *viz.* on the weſt ſide of that meridian line, making the ſame angle with it. But in expreſſing the declination, the north end of the needle is always underſtood.

In a manuſcript Latin letter of Peter Adſiger, on the properties of the magnet, dated in the year 1269; which is preſerved amongſt the manuſcripts of the univerſity of Leyden; expreſs mention is made of the declination of the magnetic needle. This curious letter was lately publiſhed by Mr. Cavallo, in the Supplement to his Treatiſe on Magnetiſm, which ſee. The conſtruction, however, of the magnetic needle, as deſcribed in this letter, being very rude and unfit for navigation, it is moſt probable that the compaſs began to be uſed at ſea many years after the above-mentioned date, and of courſe its declination remained likewiſe unknown to the generality of people, until the time of Columbus's firſt voyage to America, which took place in the year 1492; for it is expreſsly mentioned in his life, that the declination of the magnetic needle from the true meridian was firſt diſcovered in that expedition, and that this diſcovery in an unknown ocean produced a great degree of conſternation and terror in the minds of the crew; for it ſeemed as if nature herſelf had ſuſpended its uſual laws, and had forſaken them in that perilous ſituation. Some writers have attributed the original diſcovery of the declination to Sebaſtian Cabot, a Venetian, who, they ſay, diſcovered it in the year 1500; but Columbus's claim is certainly prior to that year.

The declination, when firſt diſcovered, was ſuppoſed to be permanent or unalterable; but ſome time after it was found that the quantity of it varied in the ſame place, ſo as to be different at different times. The diſcovery of this variation of the magnetical declination is generally attributed to Mr. Gellibrand, a profeſſor in Greſham college, who firſt obſerved it about the year 1625; yet Mr. Bond, in his "Longitude Found," page 5 and 6, ſays that the declination was found to vary and to decreaſe firſt by Mr. John Mair, ſecondly by Mr. Gunter, thirdly by Mr. Gellibrand, and then by himſelf in the year 1640. Since that time it has been found that the magnetic needle not only varies after a conſiderable period, but that it is continually fluctuating, ſo that the variation of it may generally be obſerved within the period of an hour or two, and often in a much ſhorter time.

The declination is not only ſubject to a continual variation in the ſame place, but it is different in different parts of the world. It alſo varies differently in each particular place; ſo much ſo, that notwithſtanding the exertions of the greateſt philoſophers and mathematicians, no theory nor rule has been diſcovered which might furniſh the means of foretelling with accuracy the declination of the magnetic needle, for any future period, at any particular place.

That the declination is not owing to any imperfection in the conſtruction of the needles or compaſſes, or to the various ſtrength of the magnets, is proved by obſerving that all the magnetic needles of compaſſes that are ſituated near the ſame ſpot, ſhew exactly the ſame declination, provided they are freely ſuſpended, and out of the influence of each other, as well as of any other ferruginous ſubſtances.

The uncertainty of the declination at different times, and in different places, being one of the greateſt impediments to the perfection of navigation; philoſophers, mathematicians, navigators, and mechanics, have endeavoured, with admirable aſſiduity, firſt, to contrive inſtruments fit to ſhew the exact quantity of it at any particular place; ſecondly, to make, and to regiſter, the obſervations in a manner that might prove uſeful to future navigators and obſervers; and thirdly, to inveſtigate the cauſe of it, principally with a view of deriving therefrom an uſeful and ſatisfactory theory. It is now incumbent upon us to treat ſucceſſively of theſe various and important particulars.

1. The inſtruments which, according to the preſent ſtate of knowledge, are beſt adapted to ſhew the declination of the magnetic needle, will be found deſcribed under the article Compass. They are of two ſorts, *viz.* one which is to be uſed at ſea, and the other which is to be uſed upon land. That which is to be uſed at ſea, on board of ſhips, is called the *azimuth compaſs*, becauſe with it the magnetic azimuth of the ſun, or other celeſtial object, is to be aſcertained at the ſame time that the true azimuth of that ſame object is obſerved by means of a ſextant; for, from the compariſon of theſe contemporary azimuths, the declination of the magnetic needle is aſcertained, according to the rules given under the above-mentioned article *Compaſs*. But it muſt not be expected that the declination, thus determined at ſea, ſhould be very accurate. With the beſt inſtruments, and the moſt expert obſervers, the declination thus found may at moſt be depended upon within eight or ten minutes; but with the common leſs perfect inſtruments, and the ordinary claſs of nautical obſervers, the reſult of the obſervations hardly ever differs from the truth leſs than half a degree; and this ariſes principally from the difficulty of obſerving the exact magnetical azimuth of the ſun, and from the difficulty of taking the true and the magnetical azimuths at the very ſame moment. Another ſource of error ariſes from the influence of iron upon the compaſs, which at ſea is almoſt impoſſible to be avoided. Captain Flinders, who made ſeveral important experiments relative to this particular, ſays (Phil. Tranſ. for 1805.) "Whilſt ſurveying along the ſouth coaſt of New Holland in 1801 and 1802, I obſerved a conſiderable difference in the direction of the magnetic needle, when there was no other apparent cauſe for it than that of the ſhip's head, being in a different direction. This occaſioned much perplexity in laying down the bearings, and in allowing

allowing a proper variation upon them, and put me under the neceſſity of endeavouring to find out ſome method of correcting or allowing for theſe differences." This gentleman then relates ſome ineffectual attempts he made for the purpoſe of removing the cauſe of the above-mentioned difference, which often amounted to ſome degrees, and was at laſt induced to draw the following inferences.

1. "I ſuppoſe," he ſays, "the attractive power of the different bodies in the ſhip, which are capable of affecting the compaſs, to be collected into ſomething like a focal point or centre of gravity, and that this point is nearly in the centre of the ſhip where the ſhot are depoſited, for here the greateſt quantity of iron is collected together."

2. "I ſuppoſe this point to be endued with the ſame kind of attraction as the pole of the hemiſphere where the ſhip is; conſequently, in New Holland the ſouth end of the needle would be attracted by it, and the north end repelled."

3. "That the attractive power of this point is ſufficiently ſtrong in a ſhip of war to interfere with the action of the magnetic poles upon a compaſs placed upon or in the binnacle."

With fixed inſtruments upon land, a much greater degree of accuracy has been attained; and it is in conſequence of this accuracy that the daily or hourly variation has been diſcovered; for the quantity of it from hour to hour is exceedingly ſmall. This accuracy, however, is to be obtained only by paying due attention to all the known particulars which have an influence on the motion and the indications of the needle. Theſe particulars principally are; 1ſt. that the magnetic meridian, or the poles of the needle, be exactly in the axis of its figure. But as this is ſeldom the caſe, the only expedient by which the error ariſing therefrom may be aſcertained and allowed for, is to turn the needle with the under ſide uppermoſt, (for which purpoſe the cap of it is generally made to fit both ſides,) and to obſerve its direction again with the laſt-mentioned ſide uppermoſt; for if the two obſervations agree, it may be concluded that the magnetic poles are in the axis of the needle; otherwiſe a mean of the two obſervations will give the true direction, and will point out the deviation of the magnetic axis of the needle from that of its figure, which, when once aſcertained, may afterwards be allowed for, without any farther inverſions of the needle. 2dly. A true meridian line muſt be had, in order to compare the direction of the needle with it. See MERIDIAN *Line*. 3dly. Care muſt be taken that the needle be not within the influence of any maſs of iron or other ferruginous matter that may be contained in the building, in the ground, or about the perſon of the obſerver. We have no better means of conveying to our readers a clear idea of the practical method of aſcertaining the above-mentioned cauſes of error, and of compenſating for their effects, than by ſubjoining part of Mr. Gilpin's account of his very careful obſervations on the variation of the magnetical declination made at the apartments of the Royal Society. This account is publiſhed in the Phil. Tranſ. for the year 1806; and the very inſtructive part of it which we allude to is as follows:

1. "The compaſs in the houſe, at the time of obſervation, was placed in the middle window, on the ſouth ſide of the ſociety's meeting-room, upon a ſtrong mahogany board. Againſt the oppoſite building the dial-plate of a watch is fixed, making an angle with the true meridian of 31° 8′.8 to the eaſtward, as a mark to which the teleſcope of the compaſs was adjuſted. To obtain the angle that this mark made with the true meridian, I fixed a tranſit-inſtrument on the mahogany board above-mentioned, preciſely in the ſame place where the compaſs had been placed, and having adjuſted its teleſcope to the ſaid mark, the tranſits of the ſun and ſtars over a vertical circle paſſing through the zenith and this mark, were obſerved; and the angle contained between the ſaid mark and the true meridian, was found by computation to be 31° 8′.8 as above.

2. "For the purpoſe of aſcertaining what error there might be, from a want of paralleliſm between the line joining the indices and the magnetiſm of the needle, and thereby to determine whether, in the uſual method of obſerving, the indices ſhew the true angle which the direction of magnetiſm makes with the firſt diviſion or zero, a great many obſervations were made on both ends of the needle, and with both ſides of the needle uppermoſt, (the cap of the needle being made to fit on readily on either face for this purpoſe); *viz.* north end and ſouth end in its upright poſition, and north end and ſouth end with the needle inverted, and the mean of the four giving the angle greater by 2′, than that ſhewn by the north end in the upright poſition of the needle, (which was the end always uſed in thoſe obſervations,) two minutes have been added to all the obſervations read from the inſtrument, as the correction for this error to angles on the eaſt ſide of zero, and ſubtracted from angles on the weſt ſide, to obtain the true angle; which error to angles on the weſt ſide, however, only occurred, when the inſtrument was taken out of doors to determine the effect of the iron-work of the building.

3. "The variation compaſs being placed in the houſe for obſervation, could not be ſuppoſed to be entirely out of the influence of iron; I was, therefore, deſirous to aſcertain how far that influence might extend; for the determination of which, the following method was adopted.

"Having cauſed to be ſunk into the earth to ſome depth a ſtrong poſt, in the wood-yard of Somerſet-houſe, at a conſiderable diſtance from the influence of any iron, on which the compaſs might be placed, and from which ſtation there was a convenient mark at a proper diſtance to which its teleſcope could be adjuſted, I took the compaſs there at thoſe times of the day when the needle was ſtationary; *viz.* morning and afternoon; before the compaſs was carried out of doors, obſervations were made in the room; then it was taken out of doors to the above-mentioned ſtation for obſervation there; and the obſervations were again repeated after the compaſs had been reſtored to its ſituation in the room; ſo that, had any alteration taken place in the interval, ſuch alteration would have been detected; but, during the whole ſeries, no material difference occurred between the obſervations made in the houſe before, and after, thoſe taken in the yard.

"The obſervations, therefore, made in the yard, compared with thoſe taken in the houſe, both before and after thoſe taken out of it, formed the compariſon for obtaining the error, or the effect of the iron-work of the room on the needle in the houſe; and there is reaſon to believe that conſiderable accuracy has been obtained. They are as follows:

"By a mean of 20 ſets, or 200 obſervations taken with the compaſs in the yard, compared with twice that number taken in the houſe, before and after thoſe taken in the yard, the variation obſerved in the houſe was found to be greater than that obſerved in the yard by 5′.4. The mean of nine ſets of obſervations taken in the morning giving for the error 5′.5. And the mean of eleven, taken in the afternoon, giving for the error 5′.3. The variation in thoſe tables have therefore been leſſened by the above-mentioned quantity 5′.4; as the error for the effect of the iron-work of the room on the needle in the houſe."

II. The obſervations of the quantity of magnetical declination which have been made and regiſtered in journals and other

other books, may, for the ſake of perſpicuity, be divided into thoſe which have been made in the ſame place at different times, and thoſe which have been made at different places and different times. We ſhall, in the firſt place, ſtate the obſervations made in London at different times.

Direction of the Magnetic Needle obſerved in London at different Times.

It may be obſerved, with reſpect to the ſtatements of the preceding table, eſpecially with thoſe previous to the year 1800, that they are not to be depended upon within leſs than three or four minutes; not ſo much on account of the imperfection of the inſtruments, or of the want of accuracy in the obſervers, as for the different times of the year, or of the day in which the obſervations were taken, which, as will preſently appear, occaſion a very material difference. And it is for this reaſon, principally, that when the declination for the ſame year is given by different obſervers about the ſame place, their ſtatements ſeldom agree.

The firſt remark which obviouſly occurs in examining the preceding table, is, that when the declination was firſt obſerved in London, the north end of the needle ſtood on the eaſt of the meridian. From that time the declination was obſerved to decreaſe, until about the year 1657, when the needle was found to point due north and ſouth; and ſoon after it was obſerved to proceed towards the weſt. But for want of a continued ſeries of obſervations, we cannot preciſely ſay when the change from eaſt to weſt actually took place.

If we take the number of years elapſed ſince the firſt obſervation was made, as ſtated in the table; *viz.* 226 years, and divide the whole angular motion of the magnetical needle, made during that period; *viz.* from 11° 15′ eaſt, to 24° 8′ weſt, we ſhall find that the mean annual motion of the declination amounts to about 9′.4; but from an inſpection of the table, and a ſeparate calculation for the number of years elapſed between each pair of contiguous obſervations, it evidently appears that the real increaſe or decreaſe of the declination has been ſo very irregular, as to indicate no rule whatever by which the declination might be foretold for any future time. Latterly, however, the decreaſe of the declination has been ſo very ſmall, as hardly to amount to ¾ of a minute annually. And from this we are led to expect that the declination has reached its ultimate limit towards the weſt, and that the north end of the needle will ſoon begin to move back towards the meridian; but no great ſtreſs ſhould be laid upon this indication; conſidering that the movements of the magnetic needle follow no certain and determinate law. Having thus ſtated the moſt remarkable obſervations relative to the annual variation of the declination, it will now be neceſſary to ſtate thoſe which relate to monthly and diurnal variation. The ingenious Mr. John Canton was the firſt who took particular care to examine the daily variation of the magnetic needle, and an account of his obſervations is contained in the 31ſt vol. of the Phil. Tranſ. His ſtatement is as follows:

The Declination obſerved at different Hours of the ſame Day.

Lately Mr. Gilpin made a great many accurate obſervations of the ſame nature at the apartments of the Royal Society, and on account of the diſtance of time, it will be uſeful to compare the mean reſult of his obſervations with

the preceding table of Mr. Canton. During 16 months, *viz.* from September 1786, to December 1787, Mr. Gilpin obſerved the direction of the magnetic needle at different ſtated hours of the day, and his obſervations are regiſtered in 16 pages of the Philoſophical Tranſactions for the year 1806, to which we muſt refer ſuch of our readers as are deſirous of examining the particulars minutely; but we ſhall ſubjoin his table of the mean monthly variation at different times of the day, which has been deduced from the above-mentioned 16 pages.

Mean Monthly Variation of the Magnetic Needle.

December		20.4	21.0	21.8	28.2	29 0	29.0	26.2	22.9	21.9	21.6	

From the whole of the above ſtated obſervations it appears, that the magnetic needle generally is ſtationary at about ſeven or eight o'clock in the morning, at which time the variation is leaſt; and at about one or two o'clock in the afternoon, when its variation is greateſt. The mean monthly diurnal variation of the declination was found, in March 1787, to be 15′; in June 19′.6; in July 19′.6; in September 14′.8; and in December 7′.6. But on a mean of twelve years obſervations, from the year 1793 to 1805, Mr. Gilpin found that the diurnal alteration of variation in March was only 8′.5; in June 11′.2; in July 10′.6; in September 8′.7; and in December 3′.7. By a mean of the above-mentioned twelve years, the variation appears to increaſe or go weſtward, from the winter ſolſtice to the vernal equinox, 0′.8; it decreaſes or goes eaſtward, from the vernal equinox to the ſummer ſolſtice, 1′.43; increaſes again, from the ſummer ſolſtice to the autumnal equinox, 2′.43; and continues nearly the ſame, only decreaſing 0′.14, from the ſaid equinox to the winter ſolſtice.

Other obſervers in other parts of the world have remarked magnetic periods ſomewhat different from the above. Mr. Cotte's obſervations, on the diurnal variation, ſhew that the magnetic needle becomes ſtationary four times in the courſe of the year; *viz.* from January to March it retires from the meridian, then approaches it till May; is ſtationary in June, retires in July, approaches it till October, and retires from it in November and December. At Fort Marlborough in the iſland of Sumatra, during the year 1794, Mr. Macdonald made ſeveral accurate obſervations on the daily variation of the declination; from which it appears that the declination at that place (where it was little more than 1° E.) increaſed from about 7 in the morning, till 5 in the afternoon, and that it decreaſed till 7 in the morning. Mr. Macdonald likewiſe obſerved that this diurnal variation of the magnetical declination in time of thunder is greater than uſual. Phil. Tranſ. for 1796.

The ſame gentleman made ſimilar obſervations in the iſland of St. Helena in the courſe of the years 1795 and 1796. The declination, which at that place was 15° 48′ $34\frac{1}{2}''$ weſt, in November 1796, at a mean appeared to vary about 3′ 55″; *viz.* the magnetic needle is ſtationary from about ſix o'clock in the evening, till ſix in the morning, when it begins to move and the weſt variation increaſes, till it amounts to its maximum, at about 8 o'clock; diminiſhing afterwards, till it becomes ſtationary. Phil. Tranſ. for 1798.

In the iſland of Jamaica Mr. Robertſon aſſerts, (Phil. Tranſ. for 1806) that the declination is conſtantly 6° 30′ eaſt. But he is led to make this aſſertion from having obſerved old plans of eſtates, made ſoon after the year 1660; whereon the magnetic meridian was marked, and which appeared to coincide with the magnetic meridian which Mr. Robertſon obſerved on purpoſe, about 140 years after the above-mentioned period. To this, however, it may be obviouſly objected, that the declination may, during the above mentioned interval, have moved backwards and forwards; and have at laſt returned to the ſame point. Beſides, it muſt be remarked, that ſurveying inſtruments, as they were made about 140 years ago, were not capable of that degree of accuracy, which is neceſſary to ſhew the true declination of the magnetic needle.

Having thus far endeavoured to give our readers a ſufficient account of the declination and its variation in the ſame place, we may now proceed to ſtate the moſt important particulars relative to the declination at different places; which is of the utmoſt conſequence to navigators.

On account of the uncertain movements of the magnetic needle in different places on the ſurface of the globe; the ſafeſt expedient which navigators can, and do, adopt, is to aſcertain the actual declination at any particular place, where it may be deemed neceſſary, by uſing the azimuth compaſs, after the manner ſhewn under the article Compass. And thus, indeed, a great many obſervations are continually made at ſea; which might be of uſe to future navigators at no great

great diſtance of time; but they are ſeldom preſerved and publiſhed; and, if publiſhed, they are to be found ſcattered in a variety of books, ſuch as tranſactions of learned ſocieties, accounts of voyages, &c. which would be too bulky and expenſive to the mariner.

The following table is a ſpecimen of the declination of the magnetic needle in different parts of the world. It conſiſts of four columns, which contain the latitude and longitude of the place, the declination, and the year in which it was obſerved.

Latitude, North.	Longitude. Weſt.	Declination, Eaſt.	Years in which the Obſervations were made.

The firſt perſon who paid particular attention to the declination of the magnetic needle in different parts of the world, was the celebrated Dr. Halley; who, in the year 1685, undertook two voyages expreſsly for this purpoſe. He collected, as far as it was in his power, all the obſervations made in different places relative to the declination of the magnetic needle, and its variation. And in order to render them uſeful to navigators in general, he marked them on a chart, which he called the *declination chart*. His method was as follows: He took a general map of the world, and he marked with dots all thoſe places in which the declination of the magnetic needle had been aſcertained; he then drew lines, whether crooked or ſtraight, through all thoſe points or places in which the declination was the ſame; for inſtance, he drew a line through all thoſe places in which the declination was 5°; he drew another line through all thoſe places in which the declination was 10°; and ſo forth. But through the points in which there was no declination either eaſtward or weſtward, he drew a double line by way of diſtinction, which of courſe is called *the line of no declination*; for in that line the magnetic needle pointed due north and ſouth. All the above-mentioned lines are called *declination lines*, or (from their firſt projector) the *Halleyan lines*. This chart was formed in the year 1700. About 60 years after, Meſſrs. Mountaine and Dodſon publiſhed a ſimilar chart of declinations, which were principally derived from obſervations made in the courſe of the years 1744 and 1756. Phil. Tranſ. for 1757.)

In Dr. Halley's chart, the line of no declination croſſes the meridian of London at about the 55th degree of ſouth latitude; it then proceeds in an arched direction towards the weſt of that meridian; and increaſing its curvature as it advances up into the northern hemiſphere, it terminates at Charles town on the coaſt of North America. In Mountaine and Dodſon's chart, the line of no declination paſſes more weſtward of the meridian of London, it advances with a more irregular curvature, and it terminates on the coaſt of Florida, at about the 30th degree of north latitude. The lines of eaſt declination are on the concave ſide of

of the above-mentioned line, and the lines of weſt declination are on its convex ſide, advancing for a conſiderable extent with nearly the ſame curvature as the line of no declination: but, as you come on this ſide of the tropic of Cancer, the lines of weſt declination, in both charts, are almoſt perpendicular to the meridians. In the Indian ſea, and in the ſea between the iſland of Madagaſcar and the ſouth pole, the declination lines are vaſtly more irregular.

There is one remarkable circumſtance to be obſerved with reſpect to the lines of declination on theſe charts, which is that they never croſs each other.

In the Berlin Memoirs for the year 1757, the celebrated Mr. Euler publiſhed his reſearches on the magnetic needle, together with a map containing the ſtate of the declination lines at about the middle of the laſt century. According to this author, the north magnetic pole of the earth ſeems, at that time, to have been ſituated near the meridian which paſſes by Cape St. Lucar, the ſouth point of California; and between the latitudes of 70° and 80° north. See the article MAGNETISM *of the Earth*.

In the year 1768, Mr. Wilcke of Sweden alſo publiſhed a declination map, wherein the lines of declination differ conſiderably from thoſe of the preceding maps.

Beſides theſe, all the moſt accurate charts of particular ſeas, ſtraits, channels, &c. generally contain the declinations of the magnetic needle at the moſt remarkable ſpots within their limits, and according to the lateſt obſervations previous to the publication of the chart. It may be obviouſly obſerved, with reſpect to the nature and the uſe of theſe declination charts, firſt, that moſt of the declination lines are drawn principally by conjecture, having not above two or three points only aſcertained, and thoſe probably not in a very accurate manner; ſecondly, that the declinations at thoſe points have been obſerved at different times; and thirdly, that though made in the moſt accurate manner imaginable, theſe charts cannot be uſeful for more than a very limited number of years. A compendious idea of the general movement of the declination lines is given by Dr. Lorimer in the following words:

"At London and Paris, where the moſt accurate obſervations have been made, towards the latter end of the ſixteenth century (and we cannot pretend to much earlier informations), there was between 11° and 12° of eaſt declination, which gradually decreaſed; ſo that in leſs than an hundred years afterwards, there was no declination at all in thoſe places. From 1657 at London, and 1666 at Paris, a weſt declination began, and has ever ſince increaſed gradually, though not uniformly, or in the direct proportion of the times; for, ſuch is the nature of the magnetic declination, that, like the apparent motion of the planets, ſometimes it is faſter, ſometimes ſlower, at other times it is ſtationary; analogous alſo to the elongations of the inferior planets, at one time it is to the eaſt, and at another time to the weſt, alternately.

"We may farther obſerve, that the declination lines of the ſame name have always reſpectively paſſed London ſome years before the ſame lines arrived at Paris; and the like obſervations have been made in other parts of the northern hemiſphere; that is, in this hemiſphere the Halleyan lines have regularly paſſed thoſe places firſt which lay moſt weſterly, and ſo in order thoſe which lay more to the eaſtward. For in the latter end of the ſixteenth century, there was an eaſtern declination over moſt parts of Europe, while on the coaſt of North America a weſt declination prevailed; the line of no declination being then ſituated about the Azores. This line of no declination has ever ſince moved gradually eaſtward, the lines of eaſt declination receding before it, while the lines of weſt declination have gradually followed it.

"In the ſouthern hemiſphere, however, it is quite otherwiſe; for, about the latter end of the ſixteenth century, a line of no declination paſſed near to the Cape of Good Hope, upon the eaſt ſide of which there was weſt declination, and upon the weſt ſide thereof eaſt declination; each of which declinations, in going eaſtward or weſtward, gradually increaſed to a certain degree, and then in the ſame manner decreaſed to nothing, ſomewhere to the eaſtward of Java, one of the Eaſt India iſlands.

"The declination in the Pacific ocean has not as yet (1775) been ſo fully aſcertained; only in general we find, that the declination is eaſterly over moſt part of that extenſive ocean. The line of no declination, which was then ſituated a little to the eaſtward of the Cape of Good Hope, has ever ſince been moving to the weſtward, and the lines of eaſt declination have gradually receded before it, while thoſe of the weſt declination have followed it with a proportional pace; ſo that at the Cape of Good Hope, there is now a conſiderable weſt declination (about 24° according to the obſervations of colonel Gordon, then commander of the Dutch forces at the Cape), and the line of no declination has moved many degrees to the weſtward thereof.

"From the preceding obſervations, then, it plainly appears, that the Halleyan lines in the ſouthern hemiſphere do gradually move from eaſt to weſt, while the motion of thoſe lines in the northern hemiſphere is from weſt to eaſt."

III. We ſhall now proceed to treat of the theory of magnetic declination, and of its variation; previouſly to which it will be proper barely to enumerate the following facts, the particular nature of which may be ſeen at large under other articles of this Cyclopædia. 1. The earth is a vaſt magnet, endowed with all the properties which have been obſerved in common magnets. 2. The magnetic needle owes its directive property to the vicinity of this great magnet, in the ſame manner as when a ſmall magnetic needle is ſimilarly ſituated upon a common globular magnet (called a *Terrella*). 3. A magnet, whether natural or artificial, may, and moſtly has, its poles not diametrically oppoſite to each other, but in any other poſition. It may alſo have more than two poles. 4. The direction of the needle muſt either coincide with, or deviate from, the meridian, according as the magnetic poles of the earth happen to be ſituated. See MAGNETISM *of the Earth*. 5. The power of a magnet is diminiſhed by heating, and is increaſed by cooling; both effects, however, within certain limits. 6. The attraction between iron and the magnetic needle is increaſed to a certain degree by the action of ſulphuric acid upon the former. (See Cavallo's Treatiſe on Magnetiſm.) 7. Laſtly, the magnetic needle has been obſerved to be diſturbed in a remarkable manner; *viz.* ſo as to vibrate and to vary irregularly, at the time of an aurora borealis, of thunder and lightning, of violent winds, of the eruptions of volcanoes, and of earthquakes.

That the earth, on account of its containing immenſe maſſes of iron, and other ferruginous minerals, is a vaſt and irregular magnet, has occurred to a variety of perſons almoſt ever ſince the diſcovery of the magnetic needle; and that as ſuch it muſt act upon the needle. But Dr. Hailey, conſidering the above-mentioned influence of iron mines, &c. as a ſecondary power, imagined that the principal movements of the needle were occaſioned by the action of a large magnet placed in or near the centre of the earth, ſo

as to form a ſort of nucleus to the earth. He alſo ſuppoſed that this magnetic nucleus had a peculiar ſlow motion, whence aroſe the declination and its variation.

Æpinus entertained nearly the ſame idea, but inſtead of admitting the peculiar motion of the nucleus, he thought that its magnetic poles only changed place; and this occaſioned the variation of the declination on the ſurface of the earth. Upon this ſuppoſition it is equally difficult to account for the change of the magnetic poles in the nucleus, as in any other part of the earth. It is mentioned by Mr. De Lalande, that Mr. Tobias Mayer ſent him an extract of an unpubliſhed memoir of his, which contains his hypotheſis concerning the magnetical movements. Mayer ſuppoſes that a very ſmall magnet, having two poles, exiſts within the earth. The centre of this magnet is removed, he ſuppoſes, from the centre of the earth by one ſeventh of its radius, and recedes from it each year one thouſandth part of that diſtance. The line drawn from the centre of the earth through that of the magnet, was, in 1750, at 201° of longitude, and 17° of north latitude: the longitude increaſes 8′ every year, and the latitude 14′.

Mr. Biot has likewiſe endeavoured to explain, by means of an interior magnet, all the declinations of the magnetic needle, that have been obſerved by Mr. Humboldt in his travels. He has attempted to determine, from the obſervations of La Peyrouſe, and Von Humboldt, all the elements of the magnetic theory of the globe; and he has given the neceſſary formula for calculating what the declination and dipping of the needle (ſee DIPPING *Needle*) ſhould be in any given place. But the calculations made, according to this formula, have not been found to agree with the actual obſervations made by Meſſrs. Humboldt, and Gay-Luſac, in their travels through Italy, France, and Germany.

Some perſons have attributed the movements of the needle to the action of celeſtial bodies, or to ſome aerial current of magnetic or electrical fluid.

Upon an attentive conſideration of all the particulars that have been aſcertained by means of experiments, and long continued obſervations, the idea of a moveable or immoveable internal magnet ſeems to be the leaſt warranted either by analogy, or by any coincidence of the theory with the obſervations. That the various parts of the earth, according to their nature, act more or leſs forcibly upon the magnetic needle, admits of no doubt. It is alſo certain that the different concurrence of heat, cold, electricity, decompoſition, and derangement, muſt continually tend to alter the quantity of the above-mentioned actions upon the magnetic needle; hence the variations of the latter muſt, according to the ſtricteſt philoſophical reaſoning, be derived from theſe adequate cauſes, without recurring to ſuppoſitions purely chimerical.

Dr. Lorimer's theory, which endeavours to explain the movements of the magnetic needle by the action of the ſolar heat upon the earth, being the moſt rational and moſt intelligible, we ſhall conclude this article with a ſtatement of it. —"It muſt be allowed, according to the obſervations of ſeveral ingenious gentlemen, that the collective magnetiſm of this earth ariſes from the magnetiſm of all the ferruginous bodies therein contained, and that the magnetic poles ſhould therefore be conſidered as the centres of the powers of thoſe magnetic ſubſtances. Theſe poles muſt therefore change their places, according as the magnetiſm of ſuch ſubſtances is affected; and if, with Mr. Canton, we allow that the general cauſe of the diurnal variation ariſes from the ſun's heat in the forenoon and afternoon of the ſame day, it will naturally occur, that the ſame cauſe, being continued, may be ſufficient to produce the general variation of the magnetic needle for any number of years. For we muſt conſider, that ever ſince any attentive obſervations have been made on this ſubject, the natural direction of the magnetic needle in Europe has been conſtantly moving from weſt to eaſt, and that in other parts of the world it has continued its motion with equal conſtancy.

"As we muſt therefore admit, that the heat in the different ſeaſons depends chiefly on the ſun, and upon the whole, that the months of July and Auguſt will probably be found the hotteſt, while January and February are the coldeſt months of the year; and that the temperature of the other months falls into the reſpective intermediate degrees; though from calculation we can ſcarce pretend to aſcertain the abſolute heat of any particular month or day; ſo we muſt conſider the influence of heat upon magnetiſm to operate in the like manner; *viz.* that for a ſhort time it ſcarcely manifeſts itſelf; yet in the courſe of a century, the conſtancy and regularity thereof becomes ſufficiently apparent. It would therefore be idle to ſuppoſe, that ſuch an influence could be derived from an uncertain and fortuitous cauſe; but if it be allowed to depend upon the conſtancy of the ſun's motion, and this appears to be a cauſe ſufficient to explain the phenomena, we ſhould, agreeably to Newton's firſt rule of philoſophizing, look no farther.

"As we therefore conſider the magnetic powers of the earth to be concentrated in the magnetic poles, and that there is a diurnal variation of the magnetic needle, theſe poles muſt perform a ſmall diurnal revolution proportional to ſuch variation, and return again to the ſame point nearly. Suppoſe then that the ſun in his diurnal revolution paſſes along the northern tropic, or along any parallel of latitude between it and the equator, when he comes to that meridian in which the magnetic pole is ſituated, he will be much nearer to it than in any other; and in the oppoſite meridian he will of courſe be the fartheſt from it. As the influence of the ſun's heat will therefore act moſt powerfully at the leaſt, and leſs forcibly at the greateſt diſtance, the magnetic pole will conſequently deſcribe a figure ſomething of the elliptical kind; and as it is well known that the greateſt heat of the day is ſome time after the ſun has paſſed the meridian, the longeſt axis of this elliptical figure will lie north-eaſterly in the northern, and ſouth-eaſterly in the ſouthern hemiſphere. Again, as the influence of the ſun's heat will not from thoſe quarters have ſo much power, the magnetic poles cannot be moved back to the very ſame point from which they ſat out; but to one which will be a little more northerly and eaſterly or more ſoutherly and eaſterly, according to the hemiſpheres in which they are ſituated. The figures therefore which they deſcribe, may more properly be termed elliptical ſpirals. The north magnetic pole may by this means be carried, with a ſlow but conſtant motion, more and more to the north-eaſtward, till it arrives at the region of the greateſt cold.

"In this manner the variation of the magnetic needle in the northern hemiſphere may be accounted for. But, with reſpect to the ſouthern hemiſphere, we muſt recollect, that though the lines of declination in the northern hemiſphere have conſtantly moved from weſt to eaſt, yet in the ſouthern hemiſphere it is equally certain that they have moved from eaſt to weſt, ever ſince any obſervations have been made on the ſubject. Is it poſſible, then, that the magnetic pole in the ſouthern hemiſphere

ſphere can move from eaſt to weſt, while that in the northern hemiſphere moves from weſt to eaſt?—I think not. But we muſt conſider this matter a little more attentively. In the firſt place, it muſt be obſerved that in ſpeaking of the declination or variation of the magnetic needle, we always refer to the north end of the needle ouly; thus, when the north end of the needle points to the weſt of the meridian, we ſay it has ſo many degrees weſt variation, though the ſouth end thereof points as many degrees to the eaſtward. Again, when the north end of the needle points to the eaſtward of the meridian, we ſay it has eaſt variation, though the ſouth end points to the weſtward thereof. And the ſame language is uſed in the ſouthern as in the northern hemiſphere; ſo that if the ſouth magnetic pole, which governs the needle in that hemiſphere, move to the eaſtward, it occaſions, as we ſay, the needle to have weſt variation; and on the contrary, if it move to the weſtward, it makes what we term eaſt variation. This therefore is the cauſe, on account of which the lines of magnetic declination, or Halleyan curves, as they are now commonly called, appear to have a contrary motion in the ſouthern hemiſphere to what they have in the northern; though both the magnetie poles of the earth move in the ſame direction, that is, from weſt to eaſt." ——————— "It is alſo curious to obſerve, that on account of the ſouthern hemiſphere being colder upon the whole than the northern hemiſphere, the magnetic poles would have moved with unequal pace; that is, the north magnetic pole would have moved farther in any given time to the north-eaſt, than the ſouth magnetic pole could have moved to the ſouth-eaſt. And, according to the opinions of the moſt ingenious authors on this ſubject, it is generally allowed, that at this time the north magnetic pole is conſiderably nearer to the north pole of the earth, than the ſouth magnetic pole is to the ſouth pole of the earth."

DECLINATION *of a vertical plane*, or *wall*, in *Dialling*, is an arc of the horizon, comprehended either between the plane and the prime vertical circle, if you account it from eaſt to weſt; or between the meridian and the plane, if you account it from north to ſouth.

There are many ways given by authors for finding the declination of planes: the moſt practicable way is by a declinator.

DECLINATOR, or DECLINATORY, an inſtrument in dialling, whereby the declination, inclination, and reclination of planes is determined.

Its ſtructure is as follows: on a ſquare wooden board A B C D (*Plate* I. *Dialling*, *fig.* 1.) deſcribe a ſemicircle A E D, and divide the two quadrants thereof A E and E D into 90 degrees each, beginning from E, as in the figure. Then, having fixed a pin in the centre F, fit a wooden ruler H I upon the ſame, moveable thereon, with a box and needle K, as ſhewn under COMPASS.

Now, to apply this, in taking the declination of a plane: apply the ſide A D of the inſtrument to the plane propoſed, as M N (*fig.* 2.); and move the ruler F G, with the compaſs G, this way and that, about the centre F, till the needle reſt upon the line of the magnetical meridian of the place. Now, if the ruler in this ſituation cut the quadrant in E, the plane is either northern or ſouthern; but if it cut between D and E, the plane declines to the weſt, or if between A and E, to the eaſt by the quantity of the angle G F E.

The ſame inſtrument will alſo ſerve to take the inclinations and reclinations of planes. To this end, inſtead of the ruler and needle, a thread with a plumbet is fitted on a pin in the centre F: then the ſide B C of the declinator A B C D, being applied to the propoſed plane, as I L (*fig.* 3.), if the plumb-line F G cut the ſemicircle A E D in the point E, the plane is horizontal: or if it cut the quadrant E D in any point at G, then will E F G be the angle of inclination: laſtly, if applying the ſide A B to the plane, the plumbet cut E, the plane is vertical. Hence, if the quantity of the angle of inclination be compared with the elevation of the pole, and equator, it is eaſily known whether the plane be inclined or reclined. See INCLINATION and RECLINATION.

DECLINATORY PLEA, in *Law*. See *Benefit of* CLERGY.

DECLINATUS, CAULIS, a declining ſtem, in *Botany*, expreſſes a ſtem bowed arch-wiſe towards the earth, as in the bramble, *Rubus fruticoſus*, and ſtill more remarkably in the *Ficus indica*, whoſe *declining* branches, taking root, make a whole grove of a ſingle tree. The term is ſynonymous with *reclinatus*, which laſt is moſt generally, though perhaps leſs properly, uſed by Linnæus.

DECLINE, in *Medicine*, a popular term applied to almoſt all chronic diſeaſes, in which the ſtrength and plumpneſs of the body gradually decline or decreaſe, until the patient dies. The term is ſynonymous with CONSUMPTION, (which ſee,) and is more particularly applied to conſumption of the lungs, and of the meſentery.

DECLINERS, or DECLINING *dials*, are thoſe which cut either the plane of the prime vertical circle, or the plane of the horizon, obliquely.

If we conceive the plane of the prime vertical circle to revolve a little upon a right line drawn from zenith to nadir, the plane will become declining; nor will it be any longer cut at right angles by the meridian, but by ſome vertical circle paſſing through the intermediate points. After the like manner an horizontal plane will be brought to decline, if revolving on the meridian line, one part of it be raiſed a little towards the zenith, and the other depreſſed towards the nadir.

The uſe of declining vertical dials is very frequent, becauſe the walls of houſes whereon dials are commonly drawn, do generally decline from the cardinal points. Incliners and recliners, and eſpecially deincliners, are very rare. See DIAL.

DECLIVITY. See ACCLIVITY.

DECLIVITIES OF MOUNTAINS. On this ſubject a number of writers have remarked, that the weſtern ſides of mountains are leſs ſteep and abrupt than their eaſtern ſides; this will in a great number of inſtances be found to ariſe from the natural riſe of the ſtrata from the S. E. toward the N. W. and the ending of the ſtrata towards the weſt, which compoſe the hill or mountain. In very diſlocated parts of a country, ruptured or broken, and precipitous ſides of hills, or mountains, are to be ſeen on all ſides, almoſt indiſcriminately: but as ſuch eminences, eſpecially if ſmall, are generally occaſioned by tilts of the ruptured pieces of ſtrata, one ſide is generally much leſs ſteep than the oppoſite one. See ENDING *of Strata*.

DECOCTION, in *Pharmacy*, is a very common and highly uſeful way of extracting the ſoluble and efficacious part of many drugs, particularly of barks, woods, and roots, and other ſubſtances which contain alſo much inert and inſoluble portion. The proportion of the ſubſtance boiled to the water ſeldom, if ever, exceeds an ounce of the former to a pint of the latter, and frequently half or a quarter of an ounce is ſufficient.

M. Boulduc aſſures us from his own experience, that the infuſions of vegetable purgatives act better, and produce better effects, than their decoctions, which he attributes to this, that the pureſt and moſt active principles of thoſe bodies are diſſipated and evaporated by a boiling heat. Me-

moires de l'Academie Royale des Sciences, an. 1710. And M. Beaumè, in his Elements of Pharmacy, obſerves, that the infuſion of Peruvian bark, made without heat, contains more of its principles than the decoction; becauſe heat ſeparates and precipitates a conſiderable quantity of reſinous ſubſtance, of which the bark conſiſts: and it is obſerved in general, that decoction ought not to be employed but when abſolutely neceſſary, or when the ſame principles and the ſame quantity of theſe principles cannot be obtained by an infuſion without heat.

Decoction *of Bark.* See Cinchona.

Decoction *of Barley.* See Barley.

Decoction *for a Clyſter*, is prepared by boiling one ounce of the dried leaves of mallow, and half an ounce of dried chamomile, in a pint of water, and ſtraining the liquor.

Decoction *of Elm*, is made by boiling four ounces of freſh elm bark, neareſt the wood, bruiſed, in four pints of diſtilled water, to two pints, and ſtraining the liquor. This decoction, given in doſes of half a pound twice or thrice a-day, is recommended in various chronical cutaneous eruptions; more eſpecially when accompanied with purging medicines.

Decoction *for Fomentation*, is made by boiling for a ſhort ſpace of time ſouthern-wood, ſea-wormwood, and chamomile, of each dried, one ounce by weight, and half an ounce by weight of dried bay-leaves, in ſix pints of diſtilled water, and ſtraining the liquor.

Decoction *of Hartſhorn*, is made by boiling, and conſtantly ſtirring, two ounces by weight, of hartſhorn burnt and prepared, and ſix drams by weight of gum arabic, in three pints of diſtilled water, to two pints, and then ſtraining. This decoction, though a much weaker abſorbent than the *mixtura cretacea*, is much more agreeable to moſt people. It is uſed as common drink in fevers, attended with laxity of bowels.

Decoction *of white Hellebore*, is prepared by boiling one ounce by weight of white hellebore, powdered, in two pints of diſtilled water to a pint, and when the liquor is cold and ſtrained, adding two ounces by weight of rectified ſpirit of wine. This is a very efficacious application in defædations of the ſkin, as in tinea, &c. It may be diluted at diſcretion.

Decoction *of Sarſaparilla.* See Sarsaparilla.

DECOLLATION, Beheading, a term frequently uſed in the phraſe, decollation of St. John Baptiſt, which denotes a painting, wherein is repreſented the Baptiſt's head, ſtruck off from his trunk; or the feaſt held in honour of that martyr.

DECOMPOSITA Folia. See Leaf.

DECOMPOSITION, Chemical, is the reſolution of a compound ſubſtance into its conſtituent parts, which are exhibited either ſeparate, or in ſome new combination. For obſervations on the limits and laws of chemical decompoſition, ſee Affinity.

Decomposition, in *Natural Hiſtory*, is that decay or change, which moſt of the ſtrata of the earth, however hard, are found to undergo when expoſed to the viciſſitudes of the atmoſphere, and often in the parts where different ſubſtances come in contact with each other; which laſt kind of decompoſition has in ſome inſtances of late been ſuppoſed to ariſe from a galvanic influence, excited by the ſuperpoſition of different kinds of ſtrata upon each other. By decompoſition it has been, that a large portion of the mould, or vegetable earth, found ſo uniformly diſtributed on the ſurface of the globe, has been formed; gravel, or heterogeneous mixtures of different ſubſtances are evidently more ſubject to decompoſition than others which are leſs compounded; and hence probably has ariſen the great depth of ſoil, aad fertility of ſome gravelly diſtricts, where quartz, pebbles, and ſand do not too much abound. The nature of ſome rocky ſtrata is ſuch, that they are never found in a hard or ſtony ſtate upon the ſurface, or at their out-crop, but are always here ſeen decompoſed, and in a ſoft or friable ſtate, although the ſame ſtratum, when covered by others, preſents a hard rock. Coal, in like manner, is always imperfect at its out-crop, and often the richeſt ſeams of this valuable ſubſtance preſent but a meer ſmut, or blackening of the earth, at their out-burſt to the day.

Decomposition is uſed by Boyle, Newton, and other Engliſh authors, to ſignify the compoſition or junction of two or more bodies, which were previouſly compounded of other parts.

DECONUS, or Doconus, in *Ancient Geography*, a river of Aſia, which had its ſource in mount Cauçaſus, and diſcharged itſelf into the Phaſis.

DECORATION, in *Architecture*, any thing that adorns and enriches a building, church, triumphal arch, or the like, either without-ſide, or within.

The orders of architecture contribute greatly to the decoration; but then the ſeveral parts of thoſe orders muſt have their juſt proportions, characters, and ornaments; otherwiſe the fineſt order will bring confuſion rather than richneſs.

Decorations in churches are paintings, vaſes, feſtoons, &c. occaſionally applied to the walls; but that with ſo much ſkill, as not to take off any thing from the form of the architecture; as is much practiſed in Italy, at the ſolemn feaſts.

Decoration is more properly applied to the ſcenes of theatres, which muſt be frequently changed, conformably to the ſubject.

The ancients had two kinds of decorations for their theatres: the firſt called verſatiles, having three ſides, or faces, which were turned ſucceſſively to the ſpectators; the other, called ductiles, ſhewing a new decoration by drawing or ſliding another before it.

The latter ſort is ſtill uſed, and apparently with much greater ſucceſs than among the ancients, who were obliged to draw a curtain whenever they made a change in the decoration; whereas in our ſtage the change is made in a moment, and almoſt without being perceived.

DECORIANA, in *Ancient Geography*, an epiſcopal town of Africa, in the Byzacene territory.

DECORTICATION, the act of peeling, or unhuſking roots, ſeeds, fruits, branches, &c. or of freeing them from their barks, rinds, huſks, or ſhells.

DECORUM, or Decor, in *Architecture*. This word is uſed by Vitruvius to expreſs the propriety or congruity of a building with reſpect to its purpoſe, ſituation, &c. which he illuſtrates by various inſtances. Thus the temples erected to Jupiter the Thunderer, to the Heavens, the Sun, or the Moon, are to be built uncovered, becauſe the influences and effects of thoſe deities are perceived in the open air. To Minerva, Mars, and Hercules, temples of the Doric order ſhould be erected; and to Venus, Flora, Proſerpine, and the Nymphs of the Fountains, Corinthian temples, the gay and graceful manner of that order correſponding with the character of the goddeſſes. To Juno, Diana, and Bacchus, the Ionic order is to be appropriated, as poſſeſſing a middle character between the ſeverity of the Doric, and the tenderneſs of the Corinthian. Decor, with regard to cuſtom, is obſerved, when the internal parts of edifices being magnificent, the acceſſes are alſo made ſuitable and

elegant. Again, if dentils are carved in the cornice of the Doric order, or, if triglyphs are repreſented in the frieze of Ionic columns, this confuſion of the characteriſtics of the orders muſt be conſidered as a violation of decorum. Decor, with regard to nature, conſiſts in all temples being placed in a ſalutary ſituation, in the neighbourhood of ſprings of water, but eſpecially the temples of Eſculapius and Health, by whoſe healing influence numbers of ſick appear to be recovered. For the diſeaſed perſons being removed from an unhealthy to a healthy ſituation, and the ſalutiferous waters of the fountains being adminiſtered, they are ſoon recovered. By this means it will happen that the natural effects of the place will increaſe the received opinion of the power of the divinity. This part of decor is alſo obſerved, when chambers and libraries receive their light from the eaſt; baths and winter apartments from the weſt; picture galleries, and ſuch rooms as require a ſteady light, from the north.

DECOUPLE', in *Heraldry*, the ſame as uncoupled, *i. e.* parted, or ſevered.

Thus a chevron decouplé is a chevron wanting ſo much towards the point, that the two ends ſtand at a diſtance from each other.

DECOURS, or Decressant, in *Heraldry*. See Decrement.

DECOY, a place made fit for catching of wild fowl.

Hence alſo a decoy-duck is one that flies abroad, and lights into company of wild ones, and, being become acquainted with them, by her allurement draws them into the decoy place, where they become a prey. See Fowl.

The decoy is uſually made where there is a large pond, ſurrounded with wood, and behind it a marſhy and uncultivated country, where the wild-fowl may ſecurely ſleep during the day-time. The decoy conſiſts of ſeveral pipes, as they are called, which lead up a narrow ditch, that cloſes at laſt with a funnel-net. Over theſe pipes, which become narrower from the firſt entrance, is fixed a continued arch of netting, ſuſpended on hoops. There is uſually a pipe or ditch for almoſt every wind that can blow, as the wild-fowl are determined by this circumſtance which pipe to chooſe; and the decoy-man always keeps on the leeward ſide of the ducks, to prevent his effluvia from reaching their ſagacious noſtrils. Skreens made of reeds are placed at certain diſtances along each pipe, in ſuch a manner, that it is impoſſible for the wild fowl to ſee the decoy-man, before they have paſſed towards the end of the pipe where the net is fixed. In the evening, when the wild-fowl begin to feed, the decoy riſes, and the noiſe of their wings, in their flight, may be heard at a great diſtance. The riſing of the decoy is in Somerſetſhire called rodding. The decoy-ducks are fed with hemp-ſeed, which is thrown in ſmall quantities over the ſkreens, to bring them forwards into the pipes, and to allure the wild-fowl to follow. They are ſo trained as to lead the way, after hearing the whiſtle of the decoy-man, and enticed by the hemp-ſeed, and to dive under water, whilſt the wild-fowl fly on, and are taken in the net. When they are in ſuch a ſleepy ſtate as not to follow the decoy-ducks, a ſmall dog is made to paſs between the ſkreens, approaching gradually nearer and nearer to the purſe-net; which draws the attention of the wild-fowl, and makes them to advance forward; at length the decoy-man appears behind a ſkreen, and drives them into the net.

The general ſeaſon for catching wild-fowl in decoys is from the latter end of October till February. The act of 10 Geo. II. cap. 32. forbids taking them from June 1 to Oct. 1, under a penalty of five ſhillings for every bird deſtroyed within that time. The Lincolnſhire decoys, which principally ſupply the London markets, are rented from 5*l.* to 20*l.* a year. Pennant's Zoology, vol. ii. p. 594. 8vo. 1776.

Decoy, in a *Military Senſe*, refers to the artifice, frequently reſorted to, either of tempting an enemy to deviate from his intended route, under the expectation of cutting off a body of troops; or of preſenting to him the appearance of weakneſs, where a ſtrong body is poſted. This kind of device ſometimes ſucceeds againſt inexperienced or ſanguine commanders; but may generally be diſtinguiſhed by the obvious pains taken to render the decoy conſpicuous. The cautious commander will ever hold in mind that ſuch military operations as are intended to be effectual, are conducted with ſecrecy and concealment; he will therefore ſuſpect every ſtudied diſplay, and, without omitting thoſe due precautions their reality might require, will conſider them as lures held out for the purpoſes of ambuſcade, or to produce a diverſion of his ſtrength towards that quarter. If he ſhould reſolve on aſcertaining the true ſtate of matters, it ought to be done in the day-time, by means of a ſmall advanced party, well ſupported by a ſufficient body. In a cloſe country too much precaution cannot be taken to prevent ſurpriſe from concealed parties: in an open country, cavalry will be the beſt to employ for reconnoitring the ſuſpicious operations; which ordinarily ſeem to peep over the brow of a hill, or from the ſkirts of woods, or along the banks of rivers and hollows.

Decoy, in *Sea Language*, denotes a ſtratagem employed by a ſmall ſhip of war to betray a veſſel of inferior force into a purſuit, till ſhe comes within gun-ſhot. The ſtern and ſides are painted ſo as to diſguiſe the ſhip, and the emblems and ornaments of the nation to which the ſtrangers belong, are aſſumed. When the adverſary is allured to chaſe, the decoy is continued by ſpreading a great ſail, as if ſhe endeavoured to eſcape; but her courſe is retarded by an artful alteration of her trim. The decoy is alſo performed for eluding the chaſe of a ſhip of ſuperior force in a dark night, by throwing out a lighted caſk of pitch, which will burn for a conſiderable time and miſguide the enemy. When the caſk is thrown out, the courſe of the eſcaping ſhip is changed.

DECREE, Decretum, an order or reſolve, made by a ſuperior power for the regulation of an inferior.

The commerce between ſoul and body, F. Malebranche obſerves, has no other vinculum, or connection, but the efficacy of the divine decrees. Second cauſes only execute the decrees of Providence.

The doctrine of the Calviniſts has been charged with implying that God concurs to ſin by a poſitive decree; in that, if crimes were not ordained by an antecedent decree, God could not foreſee the events.

Decrees of councils are the laws made by them to regulate the doctrine and policy of the church.

Decree was originally uſed by the lawyers for any thing ordained by the prince, upon cognizance of a cauſe.

But the canoniſts now reſtrain the word decree to the ordinances of popes, which form the firſt part of the canon-law; as the name canon is to what is ordained by councils.

Decrees in chancery are the determinations or ſentences of the lord chancellor, upon full hearing, and weighing the merits of the cauſe.

A decree in chancery is of the ſame nature with a judgment at common law (Chanc. Rep. 234.) Where there is but one witneſs againſt the defendant's anſwer, the plaintiff can have no decree. (1 Vern. 161.) See Court *of Chancery*.

Several queſtions and diſputes were not many years ago very warmly agitated concerning the authority of the maſter

of

of the rolls to hear and determine cauſes, and his general power in the court of chancery; to quiet which it was declared by ſtatute 3 Geo. II. c. 30. that all orders and decrees by him made, except ſuch as by the courſe of the court were appropriated to the great ſeal alone, ſhould be deemed to be valid; ſubject nevertheleſs to be diſcharged or altered by the lord chancellor, and ſo as they ſhall not be inrolled, till the ſame are ſigned by his lordſhip. In caſe of croſs cauſes, when all parties are heard, the court pronounces the decree, adjuſting every point in debate according to equity and good conſcience; which decree being uſually very long, the minutes of it are taken down, and read openly in court by the regiſtrar. The chancellor's decree is either *interlocutory* or *final*. It very ſeldom happens that the firſt decree can be final or conclude the cauſe; for, if any matter of fact is ſtrongly controverted, this court is ſo ſenſible of the deficiency of trial by written depoſitions, that it will not bind the parties thereby, but uſually directs the matter to be tried by jury; eſpecially ſuch important facts as the validity of a will, or whether A is heir at law to B, or the exiſtence of a "modus decimandi," or real and immemorial compoſition for tithes. But as no jury can be ſummoned to attend this court, the fact is uſually directed to be tried at the bar of the court of king's bench, or at the aſſiſes, upon a feigned iſſue. Thus alſo, if a queſtion of mere law ariſes in the courſe of a cauſe, it is the practice of this court to refer it to the opinion of the judges of the court of king's bench or common pleas, upon a caſe ſtated for that purpoſe, wherein all the material facts are admitted, and the point of law is ſubmitted to their deciſion; who thereupon hear it ſolemnly argued by counſel on both ſides, and certify their opinion to the chancellor. Upon ſuch certificate the decree is uſually founded. The completion of decrees is retarded by the following circumſtances. Frequently long accounts are to be ſettled, incumbrances and debts to be inquired into, and an hundred little facts to be cleared up, before a decree can do full and ſufficient juſtice. Theſe matters are always by the decree on the firſt hearing referred to a maſter in chancery to examine, which examination often laſts for years; and then he is to report the fact, as it appears to him, to the court: this report may be excepted to, diſapproved, and overruled; or otherwiſe, is confirmed, and made abſolutely order of the court.

If either party to the ſuit ſhould think himſelf aggrieved by a decree, he may petition the chancellor for a re-hearing, whether it was heard before the chancellor himſelf or any of the judges ſitting for him, or before the maſter of the rolls. For in all caſes it is the chancellor's decree, and muſt be ſigned by him before it is enrolled; which is done of courſe unleſs a re-hearing be deſired. Every petition for a re-hearing muſt be ſigned by two counſel of character, uſually ſuch as have been concerned in the cauſe, certifying that they apprehend the cauſe is proper to be re-heard. And upon the re-hearing all the evidence taken in the cauſe, whether read before or not, is now admitted to be read; becauſe it is the decree of the chancellor himſelf, who now only ſits to hear reaſons why it ſhould not be enrolled and perfected; at which time all omiſſions of either evidence or argument may be ſupplied. (Gilb. Rep. 151, 152.) But, after the decree is once ſigned and enrolled, it cannot be reheard or rectified, but by bill of review, (ſee REVIEW) or by appeal to the houſe of lords. An appeal to parliament, that is, to the houſe of lords, is the dernier reſort of the ſubject who thinks himſelf aggrieved by any interlocutory order or final determination in this court; and it is effected by petition to the houſe of peers, and not by writ of error, as upon judgments at common law. This juriſdiction is ſaid to have begun in 18 Jac. I.; and it is certain, that the firſt petition, which appears in the records of parliament, was preferred in that year; and that the firſt which was heard and determined (though the name of appeal was then a novelty) was preſented in a few months after; both levelled againſt the lord chancellor Bacon for corruption, and other miſbehaviour. It was afterwards warmly controverted in the reign of Charles II. But the diſpute is now at reſt, (Brow. Parl. c. 8.) it being obvious to the reaſon of all mankind, that when the courts of equity became principal tribunals for deciding cauſes of property, a reviſion of their decrees (by way of appeal) became equally neceſſary, as a writ of error from the judgment of a court of law. But no new evidence is admitted in the houſe of lords on any account, this being a diſtinct juriſdiction. (Gilb. Rep. 155. 156.) It is a practice unknown to our law, (though conſtantly followed in the ſpiritual courts,) when a ſuperior court is reviewing the ſentence of an inferior, to examine the juſtice of the former decree by evidence that was never produced below. Blackſt. Comm. book iii.

DECREES *of the Court of Seſſion*, in *Scots Law*, are either *in foro contradictoris*, where both parties have litigated the cauſe, or in abſence of the defender. Decrées of the ſeſſion *in foro* cannot, in the general caſe, be again brought under the review of the court, either on points which the parties neglected to plead before ſentence (which are called *competent* and *omitted*), or upon points pleaded and found inſufficient (proponed and repelled). But decrees, though *in foro*, are reverſible by the court, where either they labour under eſſential nullities, *e. g.* where they are *ultra petita*, or not conformable to their grounds and warrants, or founded on an error *in calcul*, &c. or where the party againſt whom the decree is obtained has thereafter recovered evidence ſufficient to overturn it, of which he knew not before. See SENTENCE.

Decrees in abſence of the defender, have not the force of *res judicatæ*, *i. e.* of ſentences or decrees which exclude all review or rehearing as to him; for where the defender does not appear, he cannot be ſaid to have ſubjected himſelf by the judicial contract which is implied in "conteſtatio litis;" a party therefore may be reſtored againſt theſe, upon paying to the other his coſts in recovering them. The ſentences of inferior courts may be reviewed by the court of ſeſſion; before decree, by advocation; and after decree, by ſuſpenſion or reduction; which two laſt are alſo the methods of calling in queſtion ſuch decrees of the ſeſſion itſelf, as can again be brought under the review of the court.

Decrees are reviewed either by reduction or ſuſpenſion. The former is the proper remedy, either where the decree has already received full execution by payment, or where it decrees nothing to be paid or performed, but ſimply declares a right in favour of the purſuer. For the remedy of ſuſpenſion, ſee SUSPENSION. For the execution of decrees, ſee EXECUTION.

DECREES *arbitral*, are ſentences proceeding on a ſubmiſſion to arbiters, which is a contract entered into by two or more parties who have diſputable rights or claims, by which they refer their differences to the final determination of an arbiter or arbiters, and oblige themſelves to acquieſce in what ſhall be decided. Where the day within which the arbiters are to decide is left blank in the ſubmiſſion, practice has limited the arbiters power of deciding to a year. But where a ſubmiſſion is indefinite, without ſpecifying any time, like all other contracts or obligations, it ſubſiſts for 40 years. As arbiters are not veſted with juriſdiction, they cannot compel witneſſes to make oath before them, or the exhibition of writings; but the court of ſeſſion ſupplies this defect, by granting warrants at the ſuit of the arbiters, or

of

of either of the parties, for citing witneſſes or for the exhibition of writings. The arbiters have merely power to decide; but the execution of the decree belongs to the judge. Decrees arbitral are not reducible upon any ground, except corruption, bribery, or falſehood.

DECREMENT, or DECRESSANT, in *Heraldry*, denotes the wane, or decreaſe of the moon, when ſhe is receding from the full towards the new.

In this ſtate ſhe is called, in blazon, a moon-decreſſant, or en decours; ſince to call it a creſcent, would be improper, as that term denotes an increaſe. The moon looking to the left ſide of the eſcutcheon, is always ſuppoſed to be decreſſant: when ſhe faces the right ſhe is creſcent, or in her growth.

DECREMENT, *equal, of life.* See COMPLEMENT *of life.*

DECREPITATION is the violent crackling and motion excited by ſuddenly heating any ſalt or other hard ſubſtance which contains a little water or other evaporable fluid, but much leſs than is ſufficient for liquefaction. Common ſalt affords a perfect inſtance of decrepitation when thrown on a very hot ſhovel, or in the fire.

DECREPITUDE, in *Medicine*, the conſequences of the infirmities of old age: which by degrees leads to death. See DEATH.

DECRETAL, a reſcript, or letter of a pope, whereby ſome point or queſtion in the eccleſiaſtical law is ſolved, or determined: or a digeſt of the canons of all the councils that pertained to one ſubject under one head.

The decretals, *literæ decretales*, compoſe the ſecond part of the *Canon law*, which ſee.

All the decretals attributed to the popes before Siricius, in 318, are evidently ſuppoſititious. They are ſuppoſed by ſome the ſpurious offspring of Iſidore, archbiſhop of Seville, by reaſon the collection thereof bears the name of Iſidore Peccator, or Mercator. They were firſt publiſhed by Riculph, biſhop of Mentz, in the ninth century.

Pope Gregory IX. in the thirteenth century, procured a compilation to be made of all the decretals or pontifical conſtitutions of his predeceſſors, in five books, by friar Raimond, a Dominican, his chaplain; which is the only collection authoriſed by the holy ſee to be read in ſchools.

Theſe decretals, publiſhed by Gregory IX., ſays Mr. Hume, (Hiſt. Eng. vol. ii. p. 229.) are a collection of forgeries favourable to the court of Rome, and conſiſting of the ſuppoſed decrees of popes in the firſt centuries. The forgeries are ſo groſs, and confound ſo palpably all language, hiſtory, chronology, and antiquities; matters more ſtubborn than any ſpeculative truths whatſoever; that even that church, which is not ſtartled at the moſt monſtrous contradictions and abſurdities, has been obliged to abandon them to the critics. But in the dark period of the 13th century, they paſſed for undiſputed and authentic; and even, entangled in the mazes of this falſe literature, joined to the philoſophy, equally falſe, of the times, had nothing with which to defend themſelves, but ſome ſmall remains of common ſenſe, which paſſed for profaneneſs and impiety, and the indelible regard to ſelf-intereſt, which, as it was the ſole motive in the prieſts for framing theſe impoſtures, ſerved alſo, in ſome degree, to protect the laity againſt them.

DECRETUM GRATIANI. See CANON *Law.*

DECTUNINES, in *Ancient Geography*, a people of Italy, in Liguria.

DECTURAPOUR, in *Geography*, one of the Laccadive iſlands, in the Indian ſea. N. lat. 12° 8′. E. long. 72°.

DECUARIA, in *Ancient Geography*, a town of Albion, according to the anonymous writer of Ravenna; ſuppoſed by Camden to be Beverley.

DECUBITUS, in *Medicine*, the manner or poſture in which a ſick perſon lies in bed.

This circumſtance is of conſiderable importance in the obſervation of the phyſician, as it indicates very accurately the degree and extent of ſeveral ſymptoms, by which his judgment of the event of the diſeaſe may be directed. The moſt natural and agreeable poſition of the body in bed, is when we lie on one ſide, with the limbs drawn out of the right line, or half-contracted, ſo that both ſets of muſcles, the flexors and extenſors, ſhall be in a ſtate of relaxation. When we obſerve a patient, therefore, lying in this poſition, eſpecially if ſleeping, we may infer, that he is deſtitute of great pain, that the functions are going on with freedom and eaſe, and that he is poſſeſſed of a certain degree of ſtrength. For, on the contrary, when any important organ is in pain, or diſturbed in its functions, this natural poſition of the limbs is generally altered. Thus, when the bowels and ſtomach are affected with pain, the thighs are commonly contracted inſtinctively towards the abdomen, by which the muſcles of that part are relaxed, and preſſure leſſened on the bowels. Thus alſo, when the lungs or liver are diſeaſed, the patient cannot lie on one or the other ſide. In many diſorders of the former, as in peripneumony, hydrothorax, &c. he ſits upright; not becauſe his diſeaſe is diminiſhed, as a ſuperficial obſerver might ſuppoſe, but becauſe he is threatened with ſuffocation, if he attempt to aſſume the horizontal poſture, in conſequence of the change of poſition of the fluids effuſed within the cheſt. Some degree of muſcular power is requiſite to retain the body on one ſide; ſo that in the latter ſtages of malignant fevers, and other diſeaſes of extreme debility, the failure of the vital powers is indicated by the poſture of the patient; he always is found on his back, with his limbs extended, in conſequence of the general relaxation of all the muſcles both of the trunk and limbs.

DECUMA, in *Ancient Geograghy*, a borough of Spain, dependent on the community of Colonia Patricia, or Cordova, and ſituated near the town of Sacilis (Alcorrucen), and before the confluence of the rivers Bœtis and Singulis.

DECUMÆ. See DECIMÆ.

DECUMANI, in *Ancient Geography*, a people of Gallia Narbonnenſis; ſo called, as it is ſuppoſed, becauſe they were a colony drafted from the 10th legion.

DECUMANNI DENTES, a term uſed by the Latin writers on heraldry to expreſs that ſort of line in arms, which we call danſette or dancetté. See DANCETTE.

It is a kind of indented line, but is very large, and has very few teeth, commonly no more than three. It is ſuppoſed to have been in its origin no other than the letter M, with its two legs extended from one ſide of the field to the other.

DECUMANUS. See DECIMÆ.

DECUMARIA, in *Botany*, (from *decuma* or *decima*, in alluſion to the tenfold ſtructure, not indeed very conſtant, of the flower and fruit.) Linn. Gen. 238. Schreb. 310. Wild. Sp. Pl. v. 2. 850. Juſſ. 324. (Forſythia. Walt. Carol. 154.). Claſs and Order, *Polyandria Monogynia.* Nat. Ord. *Myrti.* Juſſ.

Gen. Ch. *Cal.* Perianth urceolate, with eight, nine, or ten minute, ovate, acute, coloured teeth, at length reflexed. *Cor.* Pet. eight, nine, or ten, lanceolate, obtuſe, equal, inſerted into the rim of the calyx in a ſimple row, ſpreading. *Stam.* Filaments 16 to 27, inſerted into the calyx, thread-ſhaped, equal, as long as the petals. Anthers roundiſh, of two cells, compreſſed. *Piſt.* Germen inferior, turbinate.

Style ſhort, columnar. Stigma capitate, with about ten furrows. *Peric.* Capſule turbinate, furrowed, crowned with the calyx and ſtyle, of from eight to ten cells. *Seeds* numerous, imbricated, chaffy.

Eſſ. Ch. Calyx urceolate, with about ten teeth. Petals eight—ten. Capſule of about ten cells. Seeds numerous, imbricated, chaffy.

D. *barbara*, Linn. Sp. Pl. 1663, the only ſpecies, is a native of Carolina, not, as Schreber and Linnæus ſuppoſed, of Africa. This is a ſhrub, whoſe ſtem clinging by means of fibres to the trunks and branches of trees, climbs to a great height. The leaves are oppoſite, ſtalked, elliptical or obovate, varying iu breadth, of a deep ſhining green, veiny, ſmooth except when very young, ſerrated chiefly towards the point. Stipulas none. Flowers in a terminal corymboſe panicle, cream-coloured, fragrant, ſomewhat reſembling thoſe of the lime-tree, but ſmaller. Capſules of an elegant urn-like form, with longitudinal furrows.

This is the *Forſythia ſcandens* of Walter in his Flora Caroliniana; nor is the *Decumaria ſarmentoſa* of Boſc, Act. Soc. Hiſt. Nat. Paris, 76, t. 13, as far as we can diſcern, at all different from the above. S.

DECUPLE, in *Arithmetic*, a term of relation, or proportion, implying a thing to be ten times as much as another.

DECURIO, the chief, or commander of a decury, both in the Roman army, and in the college or aſſembly of the people. See Decury.

Decurio *municipalis*, was a name given to the ſenators of the Roman colonies.

They were called decuriones, becauſe their court or company always conſiſted of ten perſons, or becauſe, as ſome ſay, when the colony was firſt planted, every tenth man was made a ſenator. The fortune requiſite for being elected a decurio, under the emperors, was 100,000 ſeſtertii. Plin. Epiſt. i. 19. See Decury.

By means of this appointment, the cities of Italy, at leaſt, ſuch as had colonies, had a ſhare under Auguſtus, in the election of the Roman magiſtrates; the decurions, or ſenators of thoſe cities, having ſuffrages therein, which they ſent, ſealed up, to Rome, a little before the election.

Whilſt, under the emperors, every thing that was honourable or important in the adminiſtration of the revenue, was committed to the wiſdom of the præfects, and their provincial repreſentatives; the laborious offices, which could be productive only of envy and reproach, of expence and danger, were impoſed on the decuriones, who formed the corporations of the cities; and whom the ſeverity of the imperial laws had condemned to ſuſtain the burthens of civil ſociety. The title concerning the decurions (l. xii. tit. 1.) is the moſt ample in the whole Theodoſian code; ſince it contains not leſs than 192 diſtinct laws, to aſcertain the duties and privileges of that uſeful order of citizens.

Decurio was alſo a name given to certain prieſts intended, as it ſhould ſeem, for ſome particular ſacrifices, or other religious ceremonies; or for the ſacrifices of private families and houſes, as Struvius conjectures, who thence derives their name.

Be the origin of the name what it will, we have an inſcription in Gruter, which confirms what we have ſaid of their function: ANCHIALVS. CVB. AED Q TER. IN. AEDE. DECVRIO. ADLECTVS. EX. CONSENSV. DECVRIONVM. FAMILIAE. VOLVNTATA. This inſcription proves that there was a decurio in the houſe of a private perſon, Q. Terentius.

DECURION, in the armies of the ancient Roman empire, was an officer who held command over ten men, as the centurion did over an hundred. The ſyſtem of dividing their forces into very ſmall parties, each under the particular charge of an expert and approved individual, was a chief ſupport of the great power the Romans acquired over their neighbours. Military men of eminence, in our own country, have ever conſidered the diviſion of a company into very ſmall parties, each commanded by a non-commiſſioned officer, to be highly conducive to effect in the moment of conteſt; eſpecially among new levies, which are apt to be too impetuous. Hence it has been remarked that old regiments ſtand a charge with moſt coolneſs and obſtinacy; while the aſſault made by a new regiment, generally compoſed of young, ardent, and vigorous individuals, is moſt impreſſive. The plains of Maida give us a recent inſtance of a new corps making its *debut* with the defeat of nearly treble its numbers of French veterans, who could not ſtand the bayonets of the gallant ſecond battalion of the 78th, juſt raiſed in the Highlands.

It would be difficult to ſtate which of the modern ranks of ſerjeants or corporals, tallies with moſt general conformity to the ancient rank of decurion; the number of men they command being unſettled, as they uſually act according to the occaſion of the moment; and perform the general duty of the company in turn, without having charge of any particular individuals, abſtracted from the reſidue. It appears obvious, that, in this reſpect, our ſyſtem is rather deficient, and admits of a very eaſy remedy.

DECURRENTIA Folia, in *Botany*. See Leaf.

DECURSIO, in *Roman Antiquity*. See Campicursio.

DECURY, ten perſons ranged under one chief, or leader, called the decurio.

The Roman cavalry was divided into decuries.

Romulus divided the whole Roman people into three tribes over each of which he appointed a tribune: each tribe he ſubdivided into ten centuries, with centurions at their heads; and each century he ſubdivided farther into ten decuries, over each of which a decurio commanded. See Curia.

DECUSSATA Folia, in *Botany*. See Leaf.

DECUSSATION, in *Geometry* and *Optics*, the points wherein two lines or rays croſs or interſect each other: or the action itſelf of croſſing.

The rays of light decuſſate in the cryſtalline, before they reach the retina.

Decussation *of the Nerves*, in *Anatomy*. The optic nerves, ariſing ſeparately from the right and left ſides of the brain, approach each other, and unite together before leaving the ſkull. Their united portion lies juſt in front of the ſella turcica, and the right and left nerves paſſing from this, go through their reſpective foramina optica into the orbits. Anatomiſts have doubted whether or not the nerves decuſſate at this united part; ſo that the nerve ariſing from the right optic thalamus ſhould belong to the left eye, and *vice verſâ?* A direct examination of the part in queſtion is not ſufficient to determine this point: the ſubſtance of the right and left nerves is completely blended at the point of junction, but whether they croſs cannot be aſcertained. In ſeveral inſtances of diſeaſe and injury affecting one eye of an animal, the optic nerve of the diſeaſed ſide has been found diminiſhed in ſize, and altered in appearance, as far as the united portion; and theſe changes have there been continued towards the oppoſite thalamus: in ſome fiſhes they obviouſly croſs each other: in the ſkate, the right nerve goes through a fiſſure of the left; and in bony fiſhes the nerve lies on the other without any intermixture. Theſe facts are ſtrongly in favour of the ſuppoſed decuſſation in the human ſubject. An explanation of the circumſtance of our ſeeing objects ſingle with two eyes, has been ſought in this decuſſation; but, if it be admitted, we do not ſee that the phenomenon becomes more intelligible.

From

From the circumſtance of injury of one ſide of the brain generally producing paralyſis of the oppoſite ſide of the body, ſome have inferred that all the nerves decuſſate; ſo that the right ſide of the body, according to this opinion, has its nerves from the left ſide of the brain, and *vice verſâ*. The arguments from direct anatomical inveſtigation would certainly be completely againſt ſuch an opinion, as we diſcover nothing like a decuſſation of that ſort. We are ſo totally ignorant of the *manner*, in which the mind is affected, and of every thing that relates to the chain of connexion uniting external objects and the ſenſitive faculty, that we need not be ſurpriſed at not being able to explain any particular phenomena in this department of phyſiology. We have no more reaſon to infer that preſſure on one ſide of the brain ſhould affect the ſame ſide of the body, than that it ſhould paralyſe the oppoſite parts; and any inveſtigation of the reaſon why the latter event ſhould take place, will probably avail us no more than our attempts to explain how it is that we ſee objects upright, when they are painted on the retina in an inverted ſtate, in conſequence of the decuſſation of the rays of light in their paſſage through the cryſtalline lens. See S. T. Soemmerring and Noethig Diſſert. de Decuſſatione Nervorum Opticorum. Mogunt. 1796.

DECUSSIS, a Roman coin, which had different values. At firſt it was worth ten as, under Fabius ſixteen, and under Auguſtus twelve.

DECUSSORIUM, a ſurgeon's inſtrument, wherewith the dura mater is preſſed down in trepanning, to ſecure it from damage in the operation.

DECZ, or DEEZ, in *Geography*, a town of Tranſylvania, on the river Samos; 7 miles N.W. of Samoſvivar.

DEDARD, a town of Tranſylvania; 8 miles W. of Kereſztier.

DEDDINGTON, a market town in the hundred of Wootton, Oxfordſhire, England. is ſeventeen miles diſtant from Oxford, and ſixty-nine N.W. from London. It is an ancient town, was incorporated, and ſent members to parliament in the reigns of Edward I. and Edward III. It has long loſt that privilege, and is at preſent governed by a bailiff. Dr. Plot, in his Hiſtory of the County, informs us, that Deddington had once a caſtle, in which the earl of Pembroke left the famous and unfortunate favourite of Edward II., Piers Gaveſtan, under a ſtrong guard; where he was ſurpriſed by the earl of Warwick, and hurried away to Black-low hill for execution. The town is tolerably well built; and the church is a good ſtructure, having a very neat tower. Sir Thomas Pope, who was born here, A. D. 1507, and died in 1558, founded a free-ſchool, called Jeſus ſchool; before he gave the manor to Chriſt church college, Oxford. The canal from Birmingham to Oxford paſſes near the town, on which is a wharf for landing of coals to ſupply the inhabitants: an article which, previous to that communication being made to the Staffordſhire collieries, was often ſcarce and extremely dear. The place is famous for brewing excellent malt-liquor: hence it has obtained the appellation of Drunken Deddington. It has a market weekly on Saturdays, and three annual fairs. According to the returns under the late act, the number of houſes was 232, and of inhabitants 1172.

In the neighbourhood of Deddington are two mineral ſprings, celebrated for their medicinal virtues. One of them has a ſtrong ſulphureous ſcent, and contains a conſiderable portion of hepar ſulphuris, mixed with other ſulphuric neutral ſalts; and its waters produce ſimilar good effects in ſcrophulous caſes, to thoſe of Harrowgate Spaw in Yorkſhire.

DEDELER, a town of Aſiatic Turkey, in the province of Caramania; 21 miles N.W. of Conia.

DEDHAM, a large village of Eſſex, in England, was formerly a market town of ſome note, and famous for its clothing trade, as early as the reign of Richard II. Here is a free grammar ſchool, which was endowed by William Littlebury, gent. in the year 1570, for the education, &c. of twenty ſcholars. The donation was confirmed, and the governors incorporated by a charter of queen Elizabeth, dated May 14, 1574. According to the late population act of parliament, Dedham contained, in 1800, 303 houſes, and 1537 inhabitants. This town is 20 miles N.E. by E. from Colcheſter, and 58 miles N.E. by N. from London.

DEDHAM, a poſt-town of America, and the capital of Norfolk county, in the ſtate of Maſſachuſetts, called by the Aborigines Tiot, and by the firſt ſettlers Clap-board Trees. This townſhip was incorporated in 1637; it is ſeven miles long, and ſix broad, and contains 1973 inhabitants. Its public buildings are, three congregational churches, an epiſcopal church, a court-houſe, and a gaol. Its ſituation is pleaſant, 11 miles S.W. of Boſton, on Charles river. A ſmall ſtream, which joins Neponſit river, on the borders of Milton, furniſhes water for two griſt-mills, two ſaw-mills, two fulling-mills, and a leather-mill; and in this place is a wire-manufactory, which ſupplies the fiſh-hook and card-manufacturers of Boſton.

DEDI, in *Conveyances*, imports a warranty given to the feoffee and his heirs. See WARRANTY.

DEDICATION, the act of conſecrating a temple, altar, ſtatue, place, &c. to the honour of ſome deity. See TEMPLE, ALTAR, CHURCH, &c.

The uſe of dedications is very ancient, both among the worſhippers of the true God, and among the heathens: the Hebrews call it חֲנֻכָּה, *hhenuchah, initiation*; which the Greek tranſlators render εγκαινια, and εγκαινισμος, *renewing*.

In the Scripture we meet with dedications of the tabernacle, of altars, of the firſt and ſecond temple, and even of the houſes of private perſons. (Numb. vii. 10, 11. 84. 88. Deut. xx. 5. 1 Kings, viii. 63. 2 Chron. vii. 5. 9. Ezra, vi. 16, 17. 1 Eſd. vii. 7. Pſalm, xxx. 1. Heb. ix. 18.) There are alſo dedications of veſſels and garments of the prieſts and Levites, and even of the men themſelves.

Under the Chriſtian diſpenſation, we call the like ceremonies conſecrations, benedictions, ordinations, &c. and not dedications, which term is only applied to places, as to a church; and is properly the conſecration thereof performed by a biſhop, and a number of ceremonies preſcribed by the church. See CONSECRATION.

The Chriſtians, finding themſelves at liberty under Conſtantine, in lieu of their ruinous churches, built new ones in every place; and dedicated them with a great deal of ſolemnity. The dedication was uſually performed in a ſynod; at leaſt they aſſembled a number of biſhops, to aſſiſt at the ſervice. We have the deſcription of thoſe of the churches at Jeruſalem and Tyre, in Euſebius, and many others in later writers.

In the Sacramentary of Gelaſius, the dedication of the baptiſtery is delivered ſeparately from that of the church, which was performed with leſs ceremony than at preſent. The Feaſt of the Dedication, or rather the feaſt day of the ſaint or patron of a church, called, in our law-books, *dedicatio*, was celebrated not only by the inhabitants of the place, but by thoſe of all the neighbouring villages, who uſually reſorted thither; and ſuch aſſemblies were authoriſed by the

king.—" Ad dedicationes, ad ſynodos, &c. *venientes* ſit ſumma pax."

The cuſtom is ſtill retained, in diverſe places, under the name of feaſts, wakes, or vigils.

Popes Felix and Gregory are the firſt that decreed the annual obſervation of the dedication of churches, ſince our Saviour's time, which have been obſerved in England under the name of wakes or revels; but they were the occaſion of much idleneſs and debauchery, ſo that king Henry VIII. A. D. 1536, reſtrained them all to the firſt Sunday in October, prohibiting their being kept on any other day; and afterwards, by the ſtatute 5 and 6 Edward VI. c. 3. of holy-days, they were totally aboliſhed. But theſe feaſts being again revived by degrees, in ſundry places of this realm, and particularly in Somerſetſhire, judge Richardſon, when he was on the circuit, at the requeſt of the juſtices of peace for the county, publiſhed an order for ſuppreſſing them; but he was obliged the next year as publicly to revoke it, and to declare ſuch recreations to be lawful; and as a farther puniſhment on the judge, archbiſhop Laud obtained his removal from that circuit. In anſwer to a letter written by Laud to Pierce, biſhop of Bath and Wells, in which he requires fuller information on this ſubject, the biſhop acquaints him, that the late ſuppreſſion of the revels was very unacceptable, and that the reſtitution of them would be very grateful to the gentry, clergy, and common people; in proof of which he had procured the hands of 72 of his clergy, in whoſe pariſhes theſe feaſts were kept; and he believes that if he had ſent for 100 more he ſhould have had the ſame anſwer from them all; but theſe 72 (ſays his lordſhip) are like the 72 interpreters, that agreed ſo ſoon in the tranſlation of the Old Teſtament into Greek. He then proceeds to explain the nature of theſe feaſts. The feaſts of dedication, ſays he, are in memory of the dedication of their ſeveral churches; thoſe churches which are dedicated to the Holy Trinity, have their feaſts on Trinity Sunday; and ſo all the feaſts are kept upon the Sunday before or after the ſaint's day to whom the churches are dedicated, becauſe the people have not leiſure to obſerve them in the week-days:—this, ſays his lordſhip, is acceptable to the people, who otherwiſe go into tipling-houſes, or elſe to conventicles. (See *Church*-Ales.) It was one of the charges againſt Laud at his trial, that he encouraged theſe revels; and it was alleged, that they were the occaſion of many diſorders, as drunkenneſs, quarrelling, fornication, and murder; and that, therefore, it was very unlikely they ſhould anſwer any good purpoſe, and that they were unfit to ſucceed the public devotions of the Lord's day.

The Jews celebrated the anniverſary of the dedication of their temple every year, for eight days; this was firſt enjoined by Judas Maccabæus, and the whole ſynagogue, in the year of the Syro-Macedonian æra 148, *i. e.* 165 years before Chriſt, on occcaſion of the victory obtained by the Maccabees over the Greeks. (1 Maccab. iv. 59.) It begun every year on the 25th day of Ciſſeu, and was continued to the 8th day, during all which time they illuminated their houſes, by ſetting up candles at every man's door, whence it was called the feaſt of lights. This feſtival Chriſt honoured with his preſence at Jeruſalem. (John, x. 22.) Leo of Modena ſays, that they begun with one lamp, and added to the number, according to the day of the feaſt; ſo that on the laſt day they had eight lamps in their houſes. Perſius ſeems to refer to this feſtival in his 5th ſatire, v. 179—184; and it is poſſible, that the Maccabee feſtival, of the dedication of the altar, and the commemoration of the inauguration of Herod the Great, might be blended together at the time to which Perſius refers. This coincidence, which is not improbable, accounts for the ſplendour of the illuminations, which he deſcribes.

The heathens had alſo dedications of temples, altars, and images of their gods, &c. Nebuchadnezzar had a ſolemn dedication of his ſtatue. (Dan. iii. 2.) Pilate dedicated gilt bucklers at Jeruſalem, to Tiberius. (Philo de Legat.) Petronius would have dedicated a ſtatue to the emperor in the ſame city. (Ibid. p. 791.) Tacitus (Hiſt. lib. iv. cap. 53.) mentions the dedication of the Capitol, upon rebuilding it by Veſpaſian, &c.

Theſe dedications were performed with ſacrifices proper to the deity they were offered to; but they were never practiſed without public permiſſion. Among the Greeks, it does not appear who gave that permiſſion; but among the Romans, it was always the magiſtrate.

The heathens had ſimilar anniverſaries with the Jews, as that of the dedication of the temple of Parthenope, mentioned by Lycophron. The heathen temples were dedicated with many ceremonies, the principal of which were the following. The pontiffs and people encompaſſed the temple with garlands and feſtoons of flowers; the veſtal virgins, holding branches of olive trees in their hands, ſprinkled the outſide of the temple with the luſtral water; then the perſon who conſecrated, being the prætor, cenſor, &c. drew near the gate with a pontiff at his ſide, who directed him in pronouncing the words of conſecration: after which they ſacrificed a beaſt in the court of the temple, and anointed a ſtatue of the deity to whom it was dedicated with oil, and laid it on a pillar rubbed with oil. An inſcription was afterward made on ſome part of the temple, according to the name of the perſon who performed the office, and the year of dedication, which they annually obſerved by a ſacrifice, or ſome other ſolemnity.

Dedication, in *Literature*, is an addreſs prefixed to a book, ſoliciting patronage, or teſtifying reſpect for the perſon to whom it was made. The dedication of the fourth part of Mr. Edwards's Hiſtory of Birds, is curious: "To God! the one eternal! the incomprehenſible! the omnipreſent! omniſcient and Almighty Creator of all things that exiſt! from orbs immeaſurably great, to the minuteſt points of matter, this atom is dedicated and devoted, with all poſſible gratitude, humiliation, and worſhip, and the higheſt adoration both of body and mind, by his moſt reſigned, low, and humble creature, G. E."

DEDIMUS Potestatem, in *Law*, a writ whereby commiſſion is given to one or more private perſons, to aſſiſt for the expedition of ſome act belonging to a judge.

The civilians call it delegatio: it is granted moſt commonly upon ſuggeſtion, that the party who is to do ſomething before a judge, or in a court, is ſo weak that he cannot travel.

Its uſe is various: as, to take a perſonal anſwer to a bill in chancery; to examine witneſſes, or to levy a fine, &c.

DEDUCTION, in *Commerce*, a ſubtracting, or retrenching a little ſum paid, from a greater remaining to be paid.

Deduction, in *Logic* and *Science*, denotes a proceſs or chain of reaſoning, whereby, from principles ſuppoſed and allowed, we arrive at the truth of any propoſition. See Reasoning.

DEDUCTOR, in *Antiquity*, a client, who, beſides the ordinary ceremony of ſaluting his patron every morning, was likewiſe obliged to attend him on public occaſions. Pitiſc. Lex. Antiq. in voc.

DEDUCTIONE, or Deduttione, in the *Italian Muſic*, the name which Guido Aretine gave to the riſe of the voice, in pronouncing the ſyllables *ut, re, mi, fa, ſol, la: quia per has deducitur vox.* On the contrary, when the voice deſcended by *la, ſol fa, mi, re, ut,* he called it Reduttione, quia per has reducitur vox.

DEDUCTIVE Evidence, in *Ethics*, is derived either from the invariable properties or relations of general ideas, or from the actual, though perhaps variable, connections ſubſiſting among things. The former is called demonſtrative, and the latter moral. Theſe differ from one another with reſpect to their ſubject; with reſpect to their nature, as the one admits of degrees and contrariety of proofs, which the other does not, and as the former is ſimple, ariſing from a coherent ſeries of proofs mutually and eſſentially connected, and the latter is generally complicated, being compoſed of a number of isdependent proofs. Campbell's Hiſt. Rhet. vol. i. book i. chap. 5.

DEE, John, in *Biography*, an Engliſh divine and mathematician, was born in London in 1527. He received the early part of his education at different ſchools in and near the metropolis; from thence he went to St. John's college, Cambridge, where he applied himſelf to the uſual ſtudies with much diligence. In 1547 he viſited Flanders; and, on his return, was choſen fellow of Trinity college, and was admitted to the degree of M. A. His knowledge of mathematics, and his perpetual obſervations on the face of the heavens, drew upon him the imputation of a conjurer, which was never afterwards obliterated. To avoid the notice which evil-minded perſons excited by reports equally malicious and unfounded, he withdrew to Louvain, where he obtained a doctor of laws' degree. From Louvain he went to Paris, and read lectures on Euclid's Elements with much applauſe. In 1551 he returned to England, and was introduced to the king, who gave him a penſion of 100 crowns, which in a ſhort time was commuted for a royal preſentation to the rectory of Upton-upon-Severn. In the reign of Mary, he was charged with practiſing enchantments againſt the queen's life, and it was not till after much expence, trouble, and an impriſonment, that he was ſet free. In the ſucceeding reign he received better treatment. He was conſulted as to the moſt propitious day for celebrating the coronation, and his ſuppoſed ſkill in this inſtance obtained for him a high degree of credit from the principal characters at court, and even from the queen herſelf, who at length took him into her ſervice, and did him the honour of becoming his ſcholar. In 1564 he went on the continent to preſent a work, entitled, "Monas Hieroglyphica," to the emperor Maximilian. His next work, "Propedumata Aphoriſtica," he preſented to his own ſovereign in 1568, and in two years after he publiſhed a preface to ſir Henry Billinſley's tranſlation of Euclid, to which edition he added many notes of his own. In 1571 he went again to Louvain, where he was attacked by a ſerious and alarming illneſs, which afforded the queen an opportunity of ſhewing her regard and reſpect for him who had formerly been her inſtructor in aſtrology. She ſent out two phyſicians to attend him, and exhibited other marks of her beneficence. On his return he ſettled at Mortlake, in Surry. Here he collected a valuable library, and an aſtronomical and chemical apparatus, the greater part of which was deſtroyed by an ignorant mob, who conceived that the owner had ſecret dealings with the devil. In the year 1572, on the ſudden appearance of a new ſtar in Caſſiopeia's chair, and again in 1577, on the appearance of a comet, which was looked on as foreboding ſome terrible calamity, Mr. Dee obtained the higheſt reputation for the diſcourſes which he delivered explanatory of the celeſtial phenomena. The queen's ill-health in the following year afforded her a pretext for ſending Dee to Germany, to conſult ſome eminent phyſicians on her caſe; though he probably was deputed on a political errand. He was next employed to draw a geographical deſcription of the countries diſcovered by Engliſhmen in different parts of the globe: this is ſtill preſerved in the Cottonian library, on two large rolls. He now compoſed a treatiſe on the reformation of the calendar, which was highly eſteemed by the beſt mathematicians of the age, and ſtill exiſts in MS. at the Aſhmolean muſæum, Oxford. Hitherto, notwithſtanding the popular clamour excited againſt Mr. Dee, his conduct was reſpectable, and his character eſtimable. But now he ſeems to have perſuaded himſelf that an intercourſe might, by the occult ſciences, be maintained with the inhabitants of another world. He connected himſelf with a man of the name of Kelley, and they united in performing their incantations, and maintaining an imaginary intercourſe with ſpirits, until, from their neglect of every duty attached to life, they were reduced to circumſtances of want and great diſtreſs. In the year 1583, they admitted a Poliſh nobleman into their ſociety; and after they had nearly exhauſted all his reſources, they went, to avoid his creditors, to Poland, and from thence to Bohemia. Dee contrived to obtain an audience with the Poliſh ſovereign, and the emperor Rodolph, both of whom he diſguſted by his own ſelf-importance, and by a parade of projects which he was incapable of realizing. Dee and Kelley ſeparated, and the latter made himſelf maſter of the moſt valuable part of their ſtock, by which he was enabled to eſtabliſh his future fortune. Dee returned to England in the year 1589, and, through the intereſt of the queen, obtained ſome preferment in the church, with promiſe of higher honours, and more lucrative poſts, which he never obtained. His manners were haughty, his temper unconciliating, and, on account of his ſuppoſed commerce with infernal ſpirits, he became the object of hatred to thoſe with whom he was obliged to aſſociate. He petitioned for trial, in hopes of being able to free himſelf from the ſuſpicions attached to his character as a necromancer; but his prayer was not regarded, and he felt himſelf in old age without friends, and overwhelmed in poverty. He died in 1608, while he was preparing for another journey to the continent. The works of Mr. Dee were numerous; but they are now well nigh forgotten. Some unpubliſhed MSS. are ſtill preſerved in the Aſhmolean and Cottonian collections, which are ſaid to exhibit evident proofs of the author's erudition and diligence, as well as diſplay abundance of vanity and fanaticiſm. Biog. Brit.

Dee, Arthur, ſon of John, born at Mortlake, in Surry, July 14th, 1579, accompanied his father in his travels over France, Germany, and Poland, and was early initiated by him in the ſame myſteries which he himſelf had ſo unfruitfully followed. Returning to England, he ſettled in Weſtminſter, intending to practiſe medicine there; but, being rejected by the college of phyſicians, to whom he applied for a licence, he went to Ruſſia, and, on the recommendation of king James, was appointed phyſician to the czar, an office he continued to hold for fourteen years. He now returned to England, where he ſoon loſt the money he had acquired in Ruſſia, in ſearch of the grand elixir, the reality of the exiſtence of which he never doubted. He is ſaid to have died at Norwich in extreme poverty, in September, 1651. He ſuffered the cenſures of the college of phyſicians, Goodall ſays, for hanging out a table at his door, expoſing to ſale ſeveral medicines, by which he profeſſed to cure ſundry diſeaſes. While at Paris, he publiſhed, in 1631, "Faſciculus chymicus, abſtruſæ ſcien-

tiæ Hermeticæ, ingreſſum, progreſſum, coronidem explicans," 12mo. Eloy Dict. Hiſt.

DEE, in *Geography*, a river that riſes in the mountains of Merionethſhire, in North Wales, runs through Pimblemere, near Bala, and after an extenſive circuit through the county of Denbigh, which it ſeparates from Cheſhire, paſſes by Cheſter, almoſt encircling it, and after flowing to the weſt, through an artificial canal formed by the river Dee company, diſcharges itſelf into the Iriſh ſea, about 15 miles N.W. from that city. It is navigable for ſhips of 200 tons burthen up to the city of Cheſter. See CANAL. Near to Parkgate, on the northern ſhore of the eſtuary of this river, coals are dug. The freight of goods by means of this river and the ocean, would, it is ſaid, be much cheaper between Cheſter and Liverpool, than by the nearer route of the Wirral branch of the Elleſmere canal and the river Merſey, were it not for the coaſt-wiſe duties which all goods are obliged to pay in paſſing between the mouths of the Dee and Merſey rivers. The waters of this river were regarded as ſacred and purifying by our Britiſh anceſtors.

DEE, a river of Scotland, which riſes in the N.W. part of Kircudbrightſhire, from Loch Dee, and runs into Solway Frith, about five miles below Kircudbright. It is rather an eſtuary in the part which is navigable for about ſix miles from its opening into the ſea.—Alſo, a river of Scotland, which riſes in the borders of the county of Inverneſs, and runs into the German ocean at Aberdeen. It ſeparates Aberdeenſhire from the county of Mearns, and is navigable from its mouth at the harbour of New Aberdeen, to the new ſtone bridge about ſix miles above this, which was erected in the year 1801 over this river, with a principal arch of 100 feet ſpan: about the ſame time the earl Fife propoſed to clear the bed of this river upwards to the foreſt of Mar, ſo as to float the timber thereof down to new Aberdeen harbour. See CANAL. On this river is the moſt extenſive ſalmon-fiſhery in Scotland.

DEE, a ſmall river of Ireland, which, riſing in the county of Meath, enters Louth, croſſes it from weſt to eaſt, and falls into the bay of Dundalk. The town of Atherdee or Ardee is ſituated on it, and hence derives its name, which ſignifies *a ford over the Dee*.

DEE, or *Dee-obba*, a ſmall but clear river of Abyſſinia, which runs into the Nile between Abbo and Eion Mariam, about 25 geographical miles above the ſource aſſigned to it by Mr. Bruce. N. lat. 11° 25′. E. long. 36° 51′.

DEEAZED, in *Agriculture*, a provincial term which is applied to any ſort of plant or animal which is much injured or deſtroyed by the operation of cold, ſuch as vegetables which are nipped by froſt, or chicks which die in the ſhell of the egg, in conſequence of the abſence of the hen.

DEED, FACTUM, in *Law*, ſo called, κατ' εξοχην, by way of eminence, becauſe it is the moſt ſolemn and authentic act which a man can poſſibly perform, with reſpect to his property, is an inſtrument written on paper, or parchment, the validity of which conſiſts in the following particulars; proper parties to contract with one another, and a proper ſubject matter to be contracted for; a good and ſufficient conſideration; writing on paper or parchment duly ſtamped; ſufficient and legal words properly diſpoſed, comprehending the premiſes, the *habendum* and *tenendum*, the terms of ſtipulation, a condition, a clauſe of warranty, and the concluſion, mentioning the execution and date of the deed; reading, if deſired, before the execution; ſealing; and by ſtat. 29 Car. II. cap. 3. in many caſes ſigning alſo; and delivery; and which comprehends a contract, or bargain, between party and party.

If a deed wants any of the forementioned requiſites, it is void *ab initio*; and it may be alſo avoided by matter *ex poſt facto*; as by raſure, interlining, or alteration in any material part, without a memorandum made at the time of execution and atteſtation; by breaking off or defacing the ſeal; by delivering it up to be cancelled; by the diſagreement of ſuch whoſe concurrence is neceſſary; and by the judgment and decree of a court of judicature.

Of theſe there are two ſorts; deeds indented, and deeds poll; which denominations ariſe from the form and faſhion thereof; the one being cut in and out in the top, or ſide, called indented; inſtar dentium, in acute angles, but at preſent in a waving line; and the other plain, or polled.

A deed indented, or an indenture, conſiſts of two parts, or more (for there are tripartite, quadripartite, ſeptempartite, &c. deeds); wherein it is expreſſed that the parties thereto have to every part thereof interchangeably ſet their ſeveral ſeals. The cauſe of their indenting is, that whereas the ſeveral parties have each of them one, the indenture may make it appear, that they belong to one and the ſame contract by their tallying. See INDENTURE.

A deed poll, or polled, anciently called charta decima parte, or charta ſimplex, is a plain deed, without indenting; uſed when the vendor, for example, only ſeals, and there is no need for the vendee's ſealing a counter-part, becauſe the nature of the contract is ſuch, that it requires no covenant from the vendee.

DEED, *date of a*. See DATE.

DEEDS, *ſtealing of*. See LARCINY.

DEEL, in *Geography*, a ſmall river of Ireland, in the county of Mayo, which flows into the northern part of lough Conn.

DEEL-*Caſtle*, a ſmall poſt-town of Ireland, in the county of Mayo, 134 miles N. W. from Dublin, on the road from Caſtlebar to Killalla, and about five miles from the latter place.

DEEMSTERS, or DEMSTERS. All controverſies in the Iſle of Man are decided, without proceſs, writings, or any charges, by certain judges, choſen yearly from among themſelves, called deemſters. This inſtitution they are ſuppoſed to owe to the ancient Druids.

The word is formed from the Saxon *dema*, *judge*, or *umpire*.

There are two deemſters for each diviſion of the iſland: in ancient court-rolls, they are called juſticiarii domini regis. They ſit as judges in all courts, either for life or property; and with the advice of the twenty-four keys, declare what is law in uncommon emergencies.

DEENKOTE, in *Geography*, a town of Hindooſtan, in the country of Lahore, ſeated on the eaſt ſide of the Indus, or Sinde, at its junction with the Cow river, from 30 to 35 geographical miles below Attock, where is a paſs acroſs that river.

DEEP, is a term frequently applied in the ſacred writings to the ocean; the Great Deep, mentioned by Moſes in his account of the Noetic Deluge, (Gen. vii. 11.) has been ſuppoſed by Dr. Woodward (Nat. Hiſt. of Earth, p. 117.) to mean "a mighty collection of water incloſed in the bowels of the earth, conſtituting an huge orb in the interior or central parts of it; upon the ſurface of which orb of water, the terreſtrial ſtrata are expanded." Under the article CONTINENT, we have endeavoured to ſhew, that the central parts of the earth are not only ſolid, but of much greater ſpecific gravity than the ſuperficial ſtrata of the earth; and, indeed, if we conſult the Moſaic account of the decreaſe of the waters of the ſame deluge, (Gen. viii. 2.) we ſhall find the word deep only uſed, as in numerous other places, where the ſea upon the ſurface of the earth is intended to be underſtood. See ABYSS.

DEEP,

ſpace which the lines, notes, &c. are to take up. See *Plate Miſcellany, Fig.* 5.

The compoſing-ſtick ordinarily contains ſeven or eight lines of a middle-ſized letter; theſe, when ſet, are taken out, by help of a thin ſlip of braſs, termed a rule, and diſpoſed in the galley; and others compoſed, till a page be formed. The page being compoſed, is tied up, and ſet by; and the reſt of the pages of the ſheet prepared in the ſame manner: when done, they are carried to the impoſing or correcting-ſtone; there ranged in order, and diſpoſed in a chaſe, or iron-frame, fitted with wooden furniture; then, the quoins being ſtruck in, it is carried to the preſs to be printed.

Composition, in *Sculpture*, from *Compozitione*, Italian, the art of placing figures or other objects together, whether by entwining them in groups, or forming them into maſſes more nearly or diſtantly appoſed. The word bears the ſame meaning in the arts of deſign as in literature, from which it was moſt probably received, with many other terms, by the Italian artiſts at the revival of learning. Although in its moſt ſimple ſenſe it is only ſyntheſis, or joining together; yet, in its extended acceptation, it comprehends the production, order, and fitneſs of all the parts contained in the whole. The firſt elements, therefore, are invention and ſentiment; the invention ſhould be new and copious, affording an abundant choice of beautiful parts according to the ſubject, whether there be many figures or one only; the ſentiment muſt be juſt and ſtriking; according to the rule "feel yourſelf if you would make others feel;" this muſt pervade every part of the character of the figures; their action or paſſion expreſſed to the points of their fingers and toes as well as in the very folds of their drapery.

The order of compoſition contains the divine, heroic, and hiſtoric. The divine contains all ſublime and terrific ſubjects of divinities, angels, departed ſouls, and infernal miniſters. The heroic, according to the ancients, conſiſts of thoſe mortals, ſaid to have one mortal and one immortal parent. The hiſtoric claſs contains the whole ſeries of human life, in which however the moſt exalted perſons and circumſtances are always to be preferred.

The arrangement muſt be dramatic, repreſenting an action; becauſe ſentiment only affects the countenance of the figure prior to action, and words cannot be expreſſed by mute figures; therefore the ſentiments and paſſions muſt be demonſtrated by the action, in which the figures partake. The principal perſon muſt have the moſt diſtinguiſhed place, whilſt the inferiors occupy ſubordinate gradations; thus in "Prometheus chained;" Prometheus occupies the firſt intereſt and place, whilſt Force, Strength, and Vulcan are gradually inferior, although linked in the ſame group. If the hero or heroine of the ſubject be not entwined in the ſame group with other figures, he or ſhe will ſtill be diſtinguiſhed by a preferable ſituation to thoſe in which the inferior perſons are placed; this rule is obſerved in all the beſt pictures of the Herculaneum collection. In the antique baſſo-relievos and painted vaſes, and in the beſt works of antiquity, we ſcarcely ever ſee more figures introduced than ſuch as are ſufficient to tell the ſtory, and for this reaſon that the expreſſion may be the ſtronger, being leſs divided.

Outline. The general outlines of a compoſition, whether it conſiſt of one or more groups, ſhould be agreeable to the eye, which is produced by a ſucceſſion of curves of different ſegments alternately reverſed; or, in other words, a ſucceſſion of S. lines of different curvatures and dimenſions. Theſe will be more gentle in tender and graceful ſubjects, ſuch as the Triumphs of Nymphs, Naiads, and Sea Divinities, the Judgment of Paris, &c. In the antique baſſo-relievos, theſe curves become more violent with a mixture of angles in ſubjects of great exertion, ſuch as the War of the Giants, the Battles of the Lapithæ and Centaurs, the Athenians and Perſians. See Stuart's Athens, vol. iii. Muſeum Pium Clementinum. Baſſo-relievos. In the fine antique groups, as the Laocoon, Niobe and her Daughter, Cupid and Pſyche, and the Fauns and Nymphs, the lines are incatenated (chained) as it were linked into each other in whatever view they are ſeen.

Light and Shadow. Sculpture is not like painting, ſeen and forced on our perception, by the variety and brilliance of its colours. On the contrary, it has properly no colour at all; and its forms are underſtood by the effect of light and its privation, with the degrees of their medium called middle tint; theſe, in fact, produce the all of ſculptural forms to the eye, becauſe no ſuch thing as outline really exiſts, and when we ſpeak of it or uſe it, it is only to demonſtrate form geometrically. Light and ſhadow will be continually varied in the varied forms of the human figure. If ſeen abroad in the open air, or illumined from a ſky-light within doors, the light will ſtrike moſt powerfully on the head and breaſt, and gradually with leſs force on the lower part of the body and inferior limbs as they approach nearer to the earth. If the figure be recumbent, or in an horizontal poſition, thoſe parts will have moſt light which are neareſt to the luminary. If the figure be inverted, the bottoms of the feet will have the ſtrongeſt lights, which will gradually diminiſh as they approach the head; and conſequently all thoſe parts which are ſhadowed, when the figure is upright, will be lightened in this poſition, and *vice verſâ*. It muſt be remembered that, as the human figure partakes of globular forms, ſome one part will be lighter than the reſt, and that light will be brighteſt in one point. It will be found that figures in ſculpture are almoſt covered with middle tint, having a ſmall portion of bright light neareſt the luminary, with a very few dark and ſtrong ſhadows which relieve particular projections. Baſſo-relievos preſent the general effect of darkiſh figures on light back-grounds; in diſtribution of quantity, of both lines and form, that will be moſt agreeable which is inherent in the nature of things, which pervades all creation, and is more particularly evident in muſical proportion of 3ds, 5ths, and 8ths, with their ſubdiviſions and relative quantities.

We muſt however obſerve, that the rules for compoſition, like all other rules laid down for liberal art, will only aſſiſt genius; they will never produce any thing without the vigorous exertion of mental powers and manual induſtry in the ſubtle inveſtigation and diligent imitation of nature; all muſt be done by ſympathy and beautiful repreſentation; rules may be compared to the ſcaffold for raiſing a building. We muſt therefore remember that the beauties of nature are alſo various as they are endleſs, and from them only we can furniſh ourſelves with original materials for compoſition, by continually obſerving the expreſſion of ſentiment and paſſion in men, women, and children; the characters of their faces, the forms and action of their limbs, their draperies, and the manner in which the direction of the folds obſcures or indicates the bodies or limbs, in the grouping of figures; the entwining of the limbs ſhould be carefully obſerved, and the planes in which the different parts of the bodies and limbs are directed.

In the liberal arts, the ſentiment of a compoſition applies to our ſympathetic feelings, as the invention ſurprizes and delights by its novelty, and both together animate the maſs as a body is animated by the ſoul; and as no compoſition would be complete or intereſting without them, ſo when theſe vital principles are obtained, great care ſhould

men; but always in the neighbourhood of extenſive and ſolitary woods, to which they may flee in the hour of danger."

It is ſtated by the ſame writer that. "the deer, like other cattle, riſe in the bone by good keeping; and the breed degenerates when the paſture is poor. When the deer enjoyed the extenſive range of the moſt fertile valies, and were fed undiſturbed, by the moſt luxuriant graſs, he ſuppoſes they muſt have been larger in both horn and hoof, than at preſent, while baniſhed to the receſſes of the higheſt mountains, and compelled to live on ſuch coarſe fare as they can find on the mountain's brow."

Theſe animals are well ſuited as ſtock for large parks and other ſimilar grounds; and it is ſuggeſted, in the report noticed above, that there are no "ſpecies of tame animals that are more elegant in their appearance, if they be well ſelected, than the fallow deer, or better ſuited for occupying an extenſive lawn, which ſtretches round the caſtle of a great man."

It is remarked in the Report on Agriculture for the County of Hertford, that "the earl of Clarendon, juſtly conſidering that there is no more impropriety in converting one animal to profit than another, makes deer an object of huſbandry. As ſoon as the rutting ſeaſon is over, or uſually about the tenth of November, his Lordſhip ſelects from the herd, the weak ones, ſome of which would probably die in the winter, and keeps them in a ſmall yard that has a ſhed on one ſide, and a net over the whole, againſt pigeons, &c.; the ſpot very warm and well ſheltered. Their horns are immediately ſawn off, the place is well littered, and they are fed at a very ſmall expence, on pea ſtraw, hay, &c. warmth making up for the want of better food. At times during the winter, they have clover hay cut into chaff, and if they do not eat it well, a little ſalt is added. They have always plenty of water, and are kept perfectly clean: much attention ſhould be paid by the keeper, to make himſelf familiar with them, that he may enter the place without diſturbing them. The firſt week in March he gives them oil cake; about half a cake each a day, with chaff, which fattens them ſo quickly, that all are gone in May. Before killing, they have ſome green meat given, to take away any ill flavour from the cake, ſuppoſing ſuch to be the effect of the food. for it is certain that the veniſon is exceedingly good. As to weight, a haunch uſually weighs about twenty-four pounds; a brace are ſold for fifteen guineas: the ſkin worth 2*l.* 2*s.* is the keeper's perquiſite; ſo that the value of a brace amounts to 17*l.* 17*s.* excluſive of ſome trifling articles. The purchaſer ſends for them. His lordſhip uſually fattens nine brace: his whole winter ſtock riſes to three hundred and fifty head, in a park of two hundred and fifty acres, but much of it is thickly covered with timber; thirty ſheep, and ten cows alſo feed in it. The park conſumption of hay amounts to thirty-two loads, being reduced to that quantity by the uſe of much browſe; all aſh, elm, and Scotch fir, being brought for that purpoſe before faggoting, which not only ſaves hay, but improves the flavour of the veniſon."

The writer of the work mentioned above ſtates in addition that he had, "from various information, conceived that breeding deer for ſale was a very unprofitable buſineſs; but the circumſtance ſtated in this account, of ſelecting ſuch as would probably die, or be unprofitable to keep, places the eſtimate of advantage in quite a new light: thus conſidered he thinks, the ſpeculation ſeems a profitable one. It is not uncommon to hear of great winter loſſes of deer in parks, for want of a ſyſtem in which ſuch can be applied to advantage: nothing of this ſort can be well done, that is not in a regular courſe; but, by this practice, every deer which, from ſeverity of ſeaſon, or from accident, would be loſt, is converted to a great profit; as in ſuch caſes the expence of fattening is a trifle, the greater burthen of bringing them to an age for ſale, not belonging to the account of this ſyſtem. Some, it is obſerved, have fattened well, that have had their legs broken by accident."

Mr. Young remarks that, on the manure being mentioned, he made the common objection, that deer's dung is good for nothing; but this lord Clarendon conceives to be a great error: his lordſhip had an experiment made to aſcertain it; he manured for turnips, two lands; one with ſtable dung, one with deer's dung, and he left a third without manure; the two manured were nearly equal, if any difference, it was in favour of the deer; the other of courſe was much inferior. There are loop-holes in the fence through which they are ſhot. This is conſidered as a ſimple ſyſtem of management, in this branch of farming, by which much profit is capable of being derived from an animal which has hitherto been ſcarcely regarded by the farmer.

DEER-*field*, a park or place where deer are kept.

DEER-*hays*, engines, or great nets, made of cords, to catch deer. Anno 19 Hen. VII. cap. 11.

DEER's-*horns*, in *Natural Hiſtory*, are foſſile remains, bearing a conſiderable reſemblance to the horns of ſtags; ſome of theſe, found imbedded in tufa, or modern concretions of calcareous matter, as at Matlock-Bath, and at Alport in Derbyſhire, are of immenſe ſize, although pretty cloſely reſembling recent deer's horns in other reſpects. Many extraneous foſſils have been denominated deer's-horns, which are in reality the caſts of branched coraloid ſubſtances. See STAG's *Horns*.

DEER-*neck*, in *Rural Economy*, a term in the language of the breeder, which denotes a thin ill-formed neck, as applicable to horſes, neat-cattle, ſheep, &c.

DEER-*ſtealers*, in *Law*. There are ſeveral ſtatutes for the puniſhment of deer-ſtealers; as 1 Jac. I. cap. 27. againſt ſellers and buyers of deer, who are to forfeit 40*s.*—13 Car. II. cap. 10.—3 and 4 W. and M. cap. 10.—5 Geo. I. cap. 15 and 28.—9 Geo. I. cap. 22. See BLACK *Act*. 10 Geo. II. cap. 32.—28 Geo. II. c. 19. 16 Geo. III. c. 30.

By ſtat. 5 Geo. I. c. 28. wounding or killing deer in a park is puniſhable with tranſportation. By 9 Geo. I. c. 22, to hunt, wound, kill, or ſteal any deer, in the king's foreſts or chaſes incloſed, or in any other incloſed place where deer have been uſually kept; or by gift or promiſe of reward to procure any perſon to join in ſuch unlawful act: all theſe are felonies without benefit of clergy. But the principal ſtatute for the puniſhment of deer-ſtealers, is the 16 Geo. III. c. 30., which enacts, that if any perſon ſhall hunt or take in a ſnare, or kill or wound, any red or fallow deer in any foreſt, chaſe, &c. whether incloſed or not; or in any incloſed park, a paddock, &c. or be aiding in ſuch offence, they ſhall forfeit 20*l.* for the firſt offence, and alſo 30*l.* for each deer wounded, killed, or taken. A game-keeper offending, incurs the penalty of double forfeiture. For a ſecond offence thoſe who are guilty ſhall be tranſported for 7 years. Juſtices may grant warrants to ſearch for heads, ſkins, &c. of ſtolen deer, and for toils, ſnares, &c.; and perſons having ſuch in their poſſeſſion, forfeit from 30*l.* to 10*l.*, at the diſcretion of the juſtices. Perſons unlawfully ſetting nets or ſnares, forfeit for the firſt offence from 10*l.* to 5*l.*; and for every other offence from 20*l.* to 10*l.* Perſons pulling down pales, or fences of any foreſt, chaſe, park, paddock, wood, &c., are ſubject to the penalties annexed to the firſt offence for killing deer. Dogs, guns, and engines may be ſeized by park-keepers; and perſons reſiſting ſhall be tranſported

tranſported for 7 years. Penalties may be levied by diſtreſs, in default of which offenders are to be committed for 12 months. No *certiorari* to be allowed, unleſs the party convicted become bound to the proſecutor in 100*l.* to pay him all coſts and damages, and to the juſtice in 60*l.* to proſecute the *certiorari* with effect, &c. &c. Proſecutions are limited to 12 months from the time of the offence committed. By ſtat. 28 Geo. II. c. 19, deſtroying gorze, furze, and fern in foreſts and chaces, being the covert for deer, ſubjects the offenders to a penalty from 5*l.* to 40*s.* or to three months' impriſonment. For further particulars, ſee GAME and LARCINY.

DEERFIELD, in *Geography*, a poſt-town of America, in Cumberland county, and ſtate of New Jerſey; 178 miles from Waſhington.—Alſo, a very pleaſant poſt-town in Hampſhire-county, and ſtate of Maſſachuſetts, ſeated on the weſt bank of Connecticut river, from which the compact part of the town is ſeparated by a chain of high hills. It lies in the midſt of a fertile country, and has a ſmall inland trade. The compact part of the town includes from 60 to 100 houſes, and a handſome congregational church, and the number of inhabitants is 1531. An academy, incorporated in 1797, under the name of "the Deerfield academy," is eſtabliſhed in this town, diſtant from Waſhington 430 miles N.E. —Alſo, a well-ſettled agricultural town in the county of Rockingham, and ſtate of New Hampſhire, formerly a part of the townſhip of Nottingham; 19 miles S. E. of Concord, and 35 N.W. of Portſmouth; containing 1878 inhabitants, and incorporated in 1766.—Alſo, a river called *Pocomtic*, which riſes in Bennington county, Vermont, and unites a number of ſtreams from the adjoining towns on entering Maſſachuſetts; thence winding in an eaſterly direction, it receives North-river, and diſcharges itſelf into Connecticut river between the townſhips of Greenfield and Deerfield. On its banks are tracts of excellent meadow ground.

DEERING, a townſhip of America, in Hillſborough county, and ſtate of New Hampſhire, incorporated in 1774; containing 1244 inhabitants, and diſtant 15 miles S.W. of Concord, and 54 miles W. of Portſmouth.

DE ESSENDO *quietum de tolonio*, in *Law*, a writ that lies for thoſe who are by privilege freed from the payment of toll, on their being moleſted. Nat. Br. fol. 226.

DE EXPENSIS MILITUM, a writ commanding the ſheriff to levy four ſhillings *per* day, to defray the expences of a knight of the ſhire attending in parliament. See KNIGHT.

There is a like writ *de expenſis civium & burgenſium*, to levy two ſhillings per day for every citizen and burgeſs in parliament. 23 Henry VI. cap. 14. See BURGESS.

DE FACTO, ſomething actually in fact, or exiſting; in contradiſtinction to *de jure*, where a thing is only ſo in juſtice, or equity, but not in fact.

After the revolution, the retainers of the abdicated king inſiſted much on the difference between a king *de jure* and *de facto*, or a prince in actual but not legal poſſeſſion of the crown, and another who had the right but not the poſſeſſion. The non-jurors held the pretender for king *de jure*; and only allowed king George for king *de facto*.

DEFAIT, or DECAPITE', a term uſed by the French *Heralds* to denote a beaſt whoſe head is cut off ſmooth; in which it differs from eraſed, where the head is, as it were, torn off, and the neck left ragged.

DEFALCATION, from the French *defalquer*, to *diminiſh*, denotes the deduction or ſubtraction of a ſmall ſum, in matters of account, from a large one.

DEFAMATION, in *Law*, is when a perſon ſpeaks ſcandalous words of another, or of a magiſtrate, &c. whereby they are injured in their reputation; for which the party offending ſhall be puniſhed, according to the nature and quality of the offence; ſometimes by action on the caſe at common law, ſometimes by ſtatute, and ſometimes by eccleſiaſtical law. But defamation is alſo puniſhable by the ſpiritual courts; in which courts it ought to have three incidents; firſt, it is to concern matters ſpiritual, and determinable in the eccleſiaſtical courts; as for calling a man heretic, ſchiſmatic, adulterer, fornicator, &c. Secondly, that it be a matter ſpiritual only; for if the defamation concern any thing determinable at the common law, the eccleſiaſtical judges ſhall not have conuſance thereof. And thirdly, though ſuch defamation be merely ſpiritual, yet he that is defamed cannot ſue for damages in the eccleſiaſtical courts, but the ſuit ought to be only for puniſhment of the fault by way of penance. Terms de Ley, 224, 225.

DEFAMATORY, a term chiefly uſed in the phraſe defamatory libel, ſignifying a writing intended to ſcandalize or diſcredit a perſon, &c.

By the Roman law, and the ancient ordonnances of France, the authors of defamatory libels were puniſhed with death. See Balduin. Comment. ad Leges de Libellis famoſis.

But the hiſtorian tells us, that cardinal Ximenes was inſenſible to all defamatory libels; he found it but reaſonable to leave inferiors the liberty of venting their grief by writings, which only live while the perſon is offended at them, and loſe all their ſpirit and malignity when deſpiſed or diſregarded.

DEFAN, CAPE, in *Geography*, the laſt cape of the ſhore of Abyſſinia, before you run into the ſtraits of Babelmandeb; it is called by the Portugueſe *Cape Daſui*. This, ſays Mr. Bruce, has no meaning in any language; the Abyſſinians, on whoſe ſide it is, call it *Cape Defan*, or the cape of Burial, probably becauſe the eaſt wind drove aſhore thoſe who had been ſhipwrecked in the voyage. See GARDEFAN.

DEFAULT, in *Law*, non-appearance, before a court of juſtice, at a day aſſigned, or an omiſſion of what a perſon ought to do. (Bract. lib. v. tract. 3. Co. Litt. 259.) If a plaintiff makes default in appearance in a trial at law, he will be non-ſuited; and where a defendant makes default, judgment ſhall be had againſt him by default. See JUDGMENT, and NONSUIT. By default of a defendant, he is ſaid to be generally out of court to all purpoſes, but only that judgment may be given againſt him; and no judgment can be afterwards given for the defendant. (1 Nelſ. Abr. 628.) Suffering judgment to go by default is an admiſſion of the contract declared on. (Stra. 612.) After the inqueſt is taken by default, the defendant can make no ſuggeſtion on the roll. (Str. 46.)

Jurors making default in their appearance for trying of cauſes ſhall loſe and forfeit iſſues, unleſs they have a reaſonable excuſe proved by witneſſes, in which caſe the juſtices may diſcharge the iſſue for default. Stat. 35 Hen. VIII. c. 6. See JURY.

DEFEASANCE, or DEFEAZANCE, (from the French *defaire*, to *defeat*,) is of two ſorts; 1. A collateral deed, made at the ſame time with a feoffment or other conveyance, containing certain conditions, upon the performance of which the eſtate then created may be *defeated*, or totally undone. In this manner mortgages were in former times uſually made; the mortgager infeoffing the mortgagee, and he at the ſame time executing a deed of defeazance, whereby the feoffment was rendered void on repayment of the money borrowed at a certain day. And this, when executed at the ſame time with the original feoffment, was conſidered as part of it by the ancient law (Co. Litt. 236); and, therefore, only indulged; no ſubſequent ſecret accommodation of a ſolemn conveyance,

veyance, executed by livery or ſeiſin, being allowed in thoſe days of ſimplicity and truth; though, when uſes were afterwards introduced, a revocation of ſuch uſes was permitted by the courts of equity. But things that were merely executory, or to be completed by matter ſubſequent, (as rents, of which no ſeiſin could be had till the time of payment; and ſo alſo annuities, conditions, warrranties, and the like) were always liable to be recalled by defeazances made ſubſequent to the time of their creation. (Co. Litt. 237.) 2. A defeazance, on a bond, or recognizance, or judgment recovered, is a condition, which, when performed, defeats or undoes it, in the ſame manner as a defeazance of an eſtate beforementioned. It differs only from the common condition of a bond, in that the one is always inſerted in the deed or bond itſelf; the other is made between the ſame parties by a ſeparate, and frequently a ſubſequent deed. (Co. Litt. 237. 2 Sand. 47.) This, like the condition of a bond, when performed, diſcharges and diſencumbers the eſtate of the obligee. To make a good defeazance it muſt be, 1. By deed; for there cannot be a defeazance of a deed without a deed; and a writing under hand doth not imply it to be a deed. 2. It muſt recite the deed it relates to, or at leaſt the moſt material part thereof. 3. It is to be made between the ſame perſons who were parties to the firſt deed. 4. It muſt be made at the time of, or after, the firſt deed, and not before. 5. It ought to be made of a thing defeaſible. 1 Inſt. 236. 3 Lev. 234.

DEFEAT, in a *Military Acceptation*, relates to the inability of an army to reſiſt the attack of another, and its yielding the field to the ſuperior power of its adverſary. Such we may, for the moſt part, conſider to be the juſt definition of this term; and we may, generally ſpeaking, view a defeat as being attended with certain loſſes and diſadvantages. But we have numerous inſtances on record, wherein it appears that armies driven from the field, have retired under ſuch reſpectable circumſtances, and with their power ſo perfectly compacted, as to render it imprudent, nay impracticable, to purſue, or to follow up the victory. It is, in fact, under the circumſtance of inability to maintain his ground, that a general's abilities will become moſt conſpicuous. If the arrangement has been made merely upon a curſory view of the field, and without due conſideration in regard to a poſſibility of being compelled to give way, the defeat will probably be general, and fatal. If the plan has been well digeſted, and the different commanders have received inſtructions regarding their conduct in caſe of diſaſter, either to their own diviſions, or among thoſe in other parts of the army, the defeat will, in all probability, be merely a retreat; a ceſſation from attack; the abandonment of ſome particular poſt, no longer tenable; or ſome ſuch partial diſadvantage; and the whole will take a new poſition, according to previous arrangement, ſo as to make up for the failure in ſome degree, by checking purſuit, and avoiding the neceſſity of totally relinquiſhing the field. Sham defeats have occaſionally been uſed as devices for alluring troops from ſtrong holds, or for cauſing a part of the enemy's line to puſh forward in purſuit of the ſuppoſed fugitive corps; ſo that the imprudent followers might be ſuddenly flanked by parties, concealed for the purpoſe, or detached from other parts of the line; and advantage be taken of the break or vacancy, thus occaſioned in the enemy's line. Sham defeats are, however, very hazardous; it being difficult to inſpire retiring troops with confidence, or to make them rally, and return to the charge, at the preciſe moment when their doing ſo would render them certain of victory. If it were poſſible, or prudent, always to caution the body, which ſhould appear to be defeated, of the intention, ſucceſs would probably be ſecured; but amidſt the innumerable occurrences of the day, and when ſmoke and noiſe debar the poſſibility of general communication, much more of individual inſtruction, it becomes impoſſible to diſpenſe the neceſſary precautions. A commander, doubtful of the ſucceſs of an attack, ſhould defer it to a late hour; ſo that he may, if defeated, afford leſs time for the enemy to take advantage of his misfortune.

DEFECTION, the act of abandoning, or relinquiſhing, of a party, or an intereſt, a perſon had been engaged in.

The word is formed of the Latin *deficio*, *to fail of*.

DEFECTIVE, or DEFICIENT *Nouns*, in *Grammar*, are ſuch as want either a whole number or a particular caſe, or are totally indeclinable.

The term defective is alſo applied to a verb that has not all its moods and tenſes.

DEFECTIVE *Third*, in *Muſic*. See DIMINISHED *Third*, and DEFICIENT.

DEFECTIVE *Fifth*. When upon the firſt inverſion of the mixed cadence, the fifth of the ſubmediant (or fourth of the ſcale) is accidentally ſharpened, the chord of the extreme ſharp fixth is formed, the radical baſe of which is the ſupertonic of the key, and its fifth is allowed to be flat or defective, that the original minor mode may not be totally deſtroyed. See Callcott's Muſ. Gram. 219.

DEFECTIVE *Scale*. Dr Smith has applied this name to a ſyſtem of temperament deſcribed by him, wherein the major thirds and fifths beat equally quick, the former ſharp, and the latter flat; in which eight fifths in aſcending from C, and three fifths deſcending from the ſame note, are each flattened about $\frac{5}{23}$ parts of a comma, leaving a wolf between $\flat$ A and $\flat$ E, wherein the fifth is ſharpened $14\frac{7}{23}s + 1\frac{2}{23}m$. See TEMPERAMENT.

The term defective ſcales is ſometimes applied generally to all the douzeanes, or ſyſtem wherein only 12 notes are uſed within the octave.

DEFECTUM, *Challenge Propter*. See CHALLENGE.

DEFENCE, in a *Military Acceptation*, means the reſiſtance made by an inferior force, or by troops that have taken poſt within a fortified place, or that have thrown up temporary works to protect them from aſſault. The immenſe variety of circumſtances attendant on the defences of various poſts would lead us into volumes of digreſſion on hiſtorical ſubjects; we ſhall, however, ſtate, that in the event of proviſions, and warlike ſtores in general being at hand, there are few ſituations which do not admit of conſiderable protraction in regard to the term, or period, of reſiſtance. Without looking back to ancient data, when the famous ſiege of Troy attracted the attention of all the then civilized ſtates, we may refer our readers to modern events ſufficiently eminent, and exemplary, to claim the notice of thoſe who may be intereſted in this branch of honourable emulation. Perhaps we may be correct in ſtating the defence of Turin, when beſieged by the French, and defended by marſhal count Daun, to be one of the moſt brilliant exploits recorded in the annals of military hiſtory. With a very few battalions, but firmly ſupported by the public ſpirit and private eſteem of the inhabitants, he held out for near ſeven months, againſt a force of full ſeventy thouſand men, although the defences of the town were in many parts completely demoliſhed, and the greater part of the interior deſtroyed by the enemies' mortar batteries. Under ſuch circumſtances, with a perſon leſs endued with courage and reſolution, and a mind leſs capable of finding reſources in ſituations promiſing no ſupply or means of repulſion, Turin would infallibly have ſurrendered; but the count's ingenuity was equal to the diffi-

culty

culty of his ſituation, and enabled him to deviſe means for upholding the honour of his ſovereign's arms, in ſpite of the formidable attack which inceſſantly poured deſtruction around the brave handful of defenders. The count had, in the firſt inſtance, cauſed an exact inventory to be taken of all the ſtores, proviſions, merchandiſe, &c. in the town, when the enemy firſt ſat down before it. His active mind was buſied in contriving the means of appropriating every thing within the walls to their defence. Among other articles of merchandiſe were ſome thouſand bales of cotton, and a large quantity of oils. When the breach became practicable, and the enemy came to the aſſault, a quantity of the cotton, previouſly ſteeped in oil, was ſet fire to, and thrown in ſmall parcels among the ſtorming party, whoſe ammunition took fire in their pouches, and exploded, while their perſons were miſerably ſcorched by the unprecedented miſſiles; this being often repeated, the aſſailants were abſolutely diſheartened, and diſcontinued their aſſaults; converting the ſiege into a blockade. From this ſtate the brave defenders were relieved by the approach of prince Eugene, who raiſed the ſiege.

It is worthy of remark, that, by this determined defence, an army of ſeventy thouſand men was, in fact, loſt to its ſovereign for a whole campaign; while a very heavy expence, and loſs in various reſpects, neceſſarily reſulted. Hence we ſee the importance of a garriſon holding out to the laſt, and cauſing a diverſion in favour of troops acting in another quarter. With what feeling muſt the ſenſible mind contemplate the conſequences of an oppoſite conduct on the part of our allies within the laſt two years; when fortreſſes, hitherto judged impregnable, ſurrendered in many inſtances without even the ſhew of reſiſtance.

Need we uphold for an example the wonderful manner in which the brave Elliot defeated the efforts of the combined armies and navies of France and Spain, to force the ſurrender of Gibraltar! Hiſtory may record, but cannot do juſtice to, the defence made by our countrymen, not exceeding 5400 in the total, againſt upwards of 100,000 choſen men, ſupported by a numerous fleet, and in poſſeſſion of a thouſand comforts and neceſſaries, of which the garriſon were wholly deprived! We will not in this place anticipate the proceedings on that occaſion, which will be found under the head GIBRALTAR, but ſtate a recent inſtance of energy and contrivance on the part of one of Holkar's generals; a man ſuppoſed to be little acquainted with the ſcience of defence; and whoſe practice among the native powers of India, could ſcarcely claim the deſignation of experience.

When Bhurtpoor was inveſted by the army under the late lieutenant-general lord Lake, a breach had been made, which was judged practicable; *i. e.* large enough to admit the ſtorming party. The Indian general had, however, availed himſelf of the preſence of a large ſtore of raw hides, which he placed in the breach, their ends pointing inwards and outwards, in ſo artful a manner, that our grape ſhot were buried among them, and cauſed one of our parties, that proceeded to the ſtorm, to paſs the breach, miſtaking it (in the night time) for an unbattered part of the wall. It is remarkable that Bhurtpoor never ſurrendered; and, that, although a treaty was concluded under its walls, the implied ſubmiſſion of its garriſon was not underſtood.

But, as above remarked, it would not be prudent for us to enter on ſo wide a field of exemplification as the ſubject may admit; we ſhall therefore conclude with obſerving, that genius, bravery, foreſight, and fortitude, will often oppoſe ſuch formidable barriers, even where the means, ſuperficially conſidered, appear very inadequate, or indeed inſignificant, as may at leaſt retard, if not totally fruſtrate, the operations of great and well ſupplied armies. The veteran cannot but acknowledge this truth as reſulting from his own obſervation, while the tyro in the military art may, in the annals of his profeſſion, find multitudes of inſtances yielding him a rich harveſt of information, and warming his ſoul with admirable emulation.

DEFENCE, *Line of*, is that which flanks a baſtion, being drawn from the flank oppoſite to it.

The line of defence ſhould not exceed a muſket-ſhot.

The *greater*, or *fichant*, line of defence, is a right line, drawn from the point, or vertex, of the baſtion, to the concourſe of the oppoſite flank with the curtin.

The *leſſer* line of defence, called alſo *raſant*, and *flanquant*, is the face of the baſtion continued to the curtin.

DEFENCE, in *Old Law-Books*, is ſometimes uſed for prohibition.

Thus in Rot. Parl. 21 Edw. III. cries and defence were made throughout England, *i. e.* proclamation and prohibition. *Salmones ponantur in* defenſo. Stat. Weſt. 2. cap. 47. Salmons are by that act prohibited to be taken at certain times. *Uſurarios* defendit *rex Eduardus, ne remanerent in regno.* LL. Edu. Confeſſ. cap. 37. In the ſtatutes of Edward I. we have one, entitled, *Statutum de* defenſione *portandi arma*, &c. and it is defended by law, to diſtrain on the high-way.

This ſenſe of the word was probably borrowed from the French, in which language it is ſo applied.

DEFENCE, in its true legal ſenſe, denotes an oppoſing or denial of the truth or validity of the complaint, anſwering to the *conteſtatio litis* of the civilians. It is a general aſſertion which the defendant makes immediately after the count or declaration, that the plaintiff hath no ground of action; which aſſertion is afterwards extended and maintained in his plea.

The courts were formerly very nice and curious with reſpect to the nature of the defence, ſo that if no defence was made, though a ſufficient plea was pleaded, the plaintiff ſhould recover judgment (Co. Litt. 127.); and therefore the book entitled "Novæ Narrationes," or the "New Talys," (ed. 1534.) at the end of almoſt every count, *narratio*, or tale, ſubjoins ſuch defence as is proper for the defendant to make. For a general defence or denial was not prudent in every ſituation, ſince thereby the propriety of the writ, the competency of the plaintiff, and the cognizance of the court were allowed. By defending the force and injury the defendant waved all pleas of miſnomer; by defending the damages, all exceptions to the perſon of the plaintiff: and by defending either one or the other *when and where* it ſhould behove him, he acknowledged the juriſdiction of the court. (Co. Litt. 127.) But of late years theſe niceties have been very deſervedly diſcountenanced (Salk. 217. Ld. Raym. 282.); though they ſtill ſeem to be law, if inſiſted on. (Caith. 230.) A defendant cannot plead any plea before he hath made a defence; though this muſt not be intended abſolutely, for in a *ſcire facias*, a defence is never made. (3 Lev. 182.)

DEFENCE-*month* is more uſually called Fence-month. See FENCE-*month*.

DEFENCES, in *Heraldry*, are the weapons of any beaſt; as, the horns of a ſtag, the tuſks of a wild boar, &c.

DEFENCES *of a fortified Place*, include the various works intended either to cover the garriſon, or to annoy an enemy. This term comprehends a great variety of buildings, excavations, &c. for the explanation of which we muſt generally refer our readers to the heads of *Military* CONSTRUCTION and FORTIFICATION; wherein all the parts, with their ſeveral

intentions, appropriations, and proportions, will be fully exhibited. In this place we ſhall ſtate, that the defences of regular fortifications are claſſed under two diſtinct heads; *viz.* the body of the place, as delineated by an out-line called the *principal*; and the exterior defences called the *out-works*.

It is a rule held ſacred, in the theory of the art, that the defences ſhould ever be exactly proportioned to the object in view, and to the number of men that can be allotted as a garriſon. We are to take into conſideration the number of yards the defences preſent as a front, the quantity of ordnance they mount, the means of ſafely lodging the troops, and ſheltering the proviſions and ſtores requiſite for a long ſiege; the ſupply of water is alſo a primary object towards the ſecurity of which the defences muſt to a certain degree conform.

Thus we ſhould underſtand, that the defences ought never to exceed that extent which could be well manned by ſuch a garriſon as could be lodged and proviſioned; and that the garriſon ought not to exceed the reaſonable value of the occupancy. For want of due attention to theſe truly important points, it has, more than once, happened that the beſt conſtructed works have proved inefficient. The diſtribution of the various defences, ſo as to form a mutual ſupport, without ſubjecting the principal, or body of the place, to annoyance from ſuch parts as might be cut off, and poſſeſſed by the enemy, is called the *defilement*, (which ſee,) and is an indiſpenſible conſideration while planning the out-works. Whatever may be their extent, it is neceſſary, that, though temporary, ſafe lodgment ſhould be furniſhed in all out-works for the defenders, and their ſupplies; while the more retired, and concentrating parts of the fortreſs, ſhould become gradually more ſubſtantial, more elevated, and more conveniently arranged for the reception of ſuch of the defenders as may be driven in from the out-works: it being obvious, that were this precaution neglected, each diviſion of troops muſt ſurrender with the part allotted to its defence, or retire within the principal, where its preſence would create confuſion, diſeaſe, and ſcarcity.

DEFEND, Defendere, in our *Ancient Laws* and *Statutes*, ſignifies to prohibit or forbid. See Defence. 5 Rich. II. cap. 7. In which ſenſe alſo Chaucer uſes it, in the following paſſage:

> "Where can you ſay, in any manner, age,
> That ever God *defended* marriage."

See alſo Milton's Parad. Loſt, book ii. line 86.

DEFENDANT, a term in *Law*, ſignifying him who is ſued in an action perſonal; a tenant is he who is ſued in an action real.

DEFENDEMUS, a term uſed in grants and donations, having this force, that it binds the donor and his heirs to defend the donee, if any man go about to lay any incumbrance on the thing given, other than is contained in the deed of donation. Bract. lib. ii. c. 16. See Warranty.

DEFENDER of the Faith, (*Fidei Defenſor,*) is a peculiar title belonging to the king of England; as *Catholic* to the king of Spain; and *Moſt Chriſtian* formerly to the king of France, &c. Theſe titles were given by the popes of Rome; and that of *fidei defenſor* was firſt conferred by Leo X. on king Henry VIII. for writing againſt Martin Luther; and the bull for it bears date quinto idus Octob. 1521. It was afterwards confirmed by Clement VII. (Lord Herbert's Hiſt. of Henry VIII. 105.) But the pope, on Henry's ſuppreſſing the houſes of religion at the time of the Reformation, not only deprived him of his title, but depoſed him from his crown alſo: though, in the thirty-fifth year of his reign, this title, &c. was confirmed by parliament; and hath continued to be uſed by all ſucceeding kings to this day. (Lex Conſtitutionis, 47, 48.) Chamberlayne ſays, the title belonged to the kings of England before that time; and for proof hereof appeals to ſeveral charters granted to the univerſity of Oxford! So that pope Leo's bull was only a renovation of an ancient right. Preſ. ſtat. lib. i. cap. 2.

DEFENDERE Unica manu, to wage law, by denying the accuſation upon oath. "Et ſi forte forisfactor ille factum negaverit & foreſtarius ſolus ſit ſine teſte, ille debet ſe defendere unica manu ad unicam vocem rationabili die data in curia abbatis, & ſi unicum teſtem vel plures habuerit, debet ſe defendere ſexta manu, &c." Charta facta inter W. de Bray, mil & Abb. & Convent, de Oſeney, ſine dat. See Manus.

DEFENDERS were anciently notable dignitaries, both in church and ſtate; whoſe buſineſs was to look to the preſervation of the public weal, and to protect the poor and helpleſs, and to maintain the intereſts and cauſes of churches and religious houſes.

The council of Chalcedon, can. 2. calls the defender of a church, εκδικος. Codin. De Officiis Aulæ Conſt. makes mention of defenders of the palace; ſo does Bollandus, Act. S. Januar. tom. i. p. 501. There were alſo a defender of the kingdom, *defenſor regni*; defenders of cities, *defenſores civitatum*; defenders of the people, *defenſores plebis*; of the poor, fatherleſs, widows, &c.

About the year 420, each patriarchal church began to have its defender; which cuſtom was afterwards introduced into other churches, and continued to later days under other names; as thoſe of advocate and advouee. See Advocate, and Advouee.

In the year 407, we find the council of Carthage aſking the emperor for defenders, of the number of ſcholaſtici, *i. e.* advocates who were in office; and that it might be allowed them to enter, and to ſearch the cabinets and papers of the judges, and other civil magiſtrates, whenever it ſhould be found neceſſary for the intereſt of the church.

DEFENDING, in *Fortification*, is ordinarily ſynonymous with flanking. Thus we ſay the flank defends the curtin, and the oppoſite face of the baſtion; this demilune flanks, or defends the horn, or crown-work.

When they ſay the flank defends the curtin, they mean not only that it is aſide of the curtin, but, alſo, that it prevents the approaches: that is, ſuch as are poſted on the flank of a baſtion, can ſee any that come to attack the curtin; and can ſhoot them, or prevent their approaching it.

Defending-*Angle, Inner*, is the angle made by the leſſer line of defence with the curtin.

Defending-*Angle, Outer*, is the angle formed by the two leſſer lines of defence.

The lines, or ſides, of the rampart or wall, defended by muſkets or carbines, are more eaſy, cheap, and commodious, than cannons.

DEFENSITIVE, in *Surgical Pharmacy*, is a term applied to ointments, plaſters, and other applications, the uſe of which is merely to defend the ſurface, to which they are applied, from receiving injury by any accident, or from being irritated by cauſtic or by acrid diſcharges and the like.

DEFENSIVE-Allegation, in *Law*. See Allegation.

DEFENSO, that part of any open field or place, that was allotted for corn and hay, and upon which there was no common or feeding, was anciently ſaid to be *in defenſo*: ſo of any meadow ground that was laid in for hay only. It

was likewiſe the ſame of a wood, where part was encloſed and fenced up to ſecure the growth of the underwood from the injury of cattle.

DEFENSOR. See ADVOCATE.

DEFERENS VAS, in *Anatomy*, the tube which conveys the ſemen from the epididymis to the urethra. It aſcends along the back of the ſpermatic chord, enters the abdomen at the abdominal ring, takes its courſe ſubſequently over the ſide and under part of the bladder, and then penetrates the proſtate gland and urethra. For a further account of it, ſee GENERATION, *Organs of*.

DEFERENT, or DEFERENS, in the *Ancient Aſtronomy*, a circle invented to account for the eccentricity, perigee, and apogee of the planets.

As the planets are found differently diſtant from the earth, at different times, it was ſuppoſed, that their proper motion was performed in a circle, or ellipſis, which is not concentric with the earth; and this eccentric circle, or ellipſis, they call the deferent; becauſe, paſſing through the centre of the planet, it ſeemed to ſupport or ſuſtain it in its orbit.

The deferents are ſuppoſed differently inclined to the ecliptic, but none more than eight degrees, excepting that of the ſun, which is in the plane of the ecliptic itſelf, and is cut differently by the deferents of the other planets in two places called nodes.

In the Ptolemaic ſyſtem, the ſame deferent is alſo called the deferent of the epicycle; becauſe it traverſes the centre of the epicycle, and ſeems to ſuſtain it.

DEFERTINES, in *Geography*, a ſmall town of France, in the department of the Allier, three miles N. E. of Montluçon.

DEFESCH, in *Biography*, a German muſical compoſer and performer on the violin, who came to England about 1739, and frequently led the band at Marybone. He was a good contrapuntiſt, and a voluminous writer, but his productions were in general dry and unintereſting.

Mrs. Clive, after a quarrel and battle with Dr. Arne, behind the ſcenes of Drury-lane theatre, would perform none of the doctor's muſic; and when he had new ſet the Tempeſt, and prepared for her his charming air in the part of Ariel, "Where the bee ſucks," ſhe refuſed to ſing it, and employed Defeſch to ſet the ſame words, and whatever elſe ſhe had to perform in all her parts, which was a greater loſs to the public, than diſgrace to Dr. Arne, who was as ſuperior to Defeſch in genius, as Mingotti was to Clive in the art of ſinging. Yet ſo little do we know our own powers, that though ſhe was a moſt admirable and original actreſs in ſuch comic parts as Nell in "The Devil to Pay," and Mrs. Heidelberg, in the "Clandeſtine Marriage," ſhe never was ſo happy as when ſhe played lady Townley, and was attempting to ſing fine ſerious Italian ſongs: though ſhe had neither ear, voice, nor knowledge of muſic, ſo that had Defeſch's ſongs been leſs dull than they uſually were, they would never have been ſung into public favour by Mrs. Clive.

DEFIANCE. See CHALLENGE.

DEFIANCE, in *Geography*, a fort in the ſtate of Ohio, ſituated on the point of land formed by the confluence of the rivers of Au Glaize, and the Miami of the lake, nearly in the midway between fort Wayne on the Miami, and lake Erie. N. lat. 41° 41'. W. long. 84° 43'.

DEFICIENT INTERVAL, in *Muſic*, is uſed for an interval leſs than the true by a comma. See INTERVAL.

DEFICIENT *Numbers*, are ſuch whoſe parts added together make leſs than the integer, whoſe parts they are. See NUMBER.

Such *e. gr.* is 8; whoſe quota parts are 1, 2, and 4; which, together, only make 7. See ABUNDANT *Number*.

DEFICIENT *Hyperbola* is a curve of that denomination, having only one aſymptote, and two hyperbolic legs running out infinitely towards the ſide of the aſymptote, but contrary ways. (See CURVE.) This name was given to the curve by Newton in his "Enumeratio Linearum tertii ordinis." Of theſe there are 6 different ſpecies, which have no diameters, expreſſed by the equation $xyy + ey = -ax^3 + bx^2 + cx + d$, the term ax^3 being negative. When the equation $ax^4 = bx^3 + cx^2 + dx + \frac{1}{4}ee$ has all its roots real and unequal, the curve has an oval joined to it. When the two middle roots are equal, the oval joins to the legs, which then cut one another in the ſhape of a nooſe. When three roots are equal, the nodus is changed into a very acute cuſp or point. When, of three roots with the ſame ſign, the two greateſt are equal, the oval vaniſhes into a point. When any two roots are imaginary, there is only a pure ſerpentine hyperbola, without any oval, decuſſation, cuſp, or conjugate point; and when the terms b and d are wanting, it is of the 6th ſpecies. There are alſo 7 different ſpecies of theſe curves, having each one diameter, expreſſed by the above equation, when the term ey is wanting, according to the various conditions of the roots of the equation $ax^3 = bx^2 + cx + d$, as to their reality, equality, their having the ſame ſigns, or two of them being imaginary.

DEFILE, in the *Military Acceptation*, is a narrow way or path, admitting only of a few perſons (ſometimes indeed only one) proceeding a-breaſt; and uſually ſerving as the road through wilderneſſes, mountainous countries, &c. The term is derived from the thread given by Ariadne to Theſeus when he entered the celebrated labyrinth of Dædalus, king of Crete, for the purpoſe of, according to the modern term, "unthreading" the paſſage by which he had entered. Hence, when an army proceeds through cloſe countries, wherein they cannot perform evolutions, and are compelled to march by files, *i. e.* with a very narrow front, not exceeding three or four abreaſt, it is ſaid to "file off," or to "defile." Defiles are very often confounded with paſſes, though there is a very obvious diſtinction; for a defile may be of any extent, even to the length of thirty or forty miles, whereas a paſs more properly ſpeaking relates to ſome particular ſpot; like the Thermopylæ, where three hundred Greeks ſufficed to arreſt the progreſs of the hoſt, hiſtory ſays near a million, with which Xerxes threatened to over-run their country. We may form a more correct idea of the nature of defiles, if we recollect, that in the early part of the French revolution, when general Moreau was hemmed in by the Auſtrians on the borders of the Black Foreſt, he retreated through that immenſe wilderneſs towards Conſtance, cutting roads and opening paſſages by manual labour for his cannon and baggage waggons; thus his army *defiled* through the Black Foreſt, to the admiration of all Europe. From this explanation it will be ſeen that *paſſes* are defences, chiefly natural, which offer more or leſs difficulty at particular localities, while ſuch mazes as render the paſſage of troops confined and difficult, by their ruggedneſs, cloſe arborage, and meandering courſe amidſt a variety of impediments, are to be conſidered as *defiles*.

DEFILEMENT, in *Fortification*, ſignifies the branching forth of various outworks in their proper directions, ſo that the one may ſerve to ſupport the other, while, at the ſame time, all the defences depending exteriorly on any face or front, of the principal, or body of the place, may be under the command and fire of the more centrical batteries, &c., in order that the more detached parts, when carried by the enemy, may not afford a ſafe lodgment, but be open to the enfilade, or to the direct fire, of the principal.

Our readers muſt be ſenſible, that in proportion as con-

centric circles become more remote from their common centre, they neceſſarily acquire a greater perimeter, or circumference; conſequently, the outworks cover a far greater meaſurement of area, than the body of the place. This extenſion admits of, and demands a greater variety of flanks, &c, than could be deſcribed, on a proper ſcale, within a more circumſcribed ſpace. But, in the formation of ſuch exterior defences, it requires no ſmall art (we ſpeak of level ground) to arrange the whole in ſuch manner as may form a perfect ſyſtem of mutual defence, without giving the enemy a ſhelter, or eventually even a battery, from which he may be enabled to annoy the garriſon. Want of care in this particular has been fatal to many fortified places.

Fortreſſes ſituated on ground interſected by heights, or commanded by elevated batteries, are leſs in danger from the want of that defilement which is indiſpenſable in ordinary inſtances; but there muſt, in every caſe, be due regard paid to the mutual ſupport of out-works, and particular care muſt be taken to conſtruct batteries in thoſe parts which may be leaſt acceſſible, and have the greateſt range; in ſuch parts the defences ought to be adapted, not only to the general defence, but to the expulſion of the enemy from ſuch works as they may chance to carry. This, in fact, is a ſpecies of defilement, though not on that ſyſtematic plan which is prevalent in all the modern ſyſtems of regular fortification.

To DEFILE, to go off file by file. See FILE.

The army began to defile on the left, and was forced to defile at each end of the field, on account of the moraſſes and the woods.

DEFINITE, in *Grammar*, is applied to an article that has a preciſe determinate ſignification.

Such are the articles *the* in Engliſh, *le* and *la* in French, &c. which fix and aſcertain the noun they belong to, to ſome particular; as *the* king, *le* roy; whereas, in the quality *of* king, *de* roy, the articles *of* and *de*, mark nothing preciſe; and are therefore called indefinite. See ARTICLE.

DEFINITION, in *Logic*, an enumeration of the chief ſimple ideas whereof a compound idea conſiſts; in order to aſcertain or explain its nature and character.

The ſchoolmen give very imperfect notions of definition. Some define it the firſt notion, or conception, that ariſes of a thing, whereby it is diſtinguiſhed from every other, and from which all the other things, that we conceive of it, are deduced; but the uſual definition of it is, *oratio explicans quid res eſt*, a diſcourſe explaining what a thing is: that is, as ſome farther explain it, a diſcourſe ſetting forth thoſe attributes which circumſcribe and determine the nature of a thing. For, to explain is only to propoſe the parts ſeparately and expreſsly, which were before propoſed conjunctly and implicitly; ſo that every explication has regard to ſome whole. Hence, according to the diverſe kinds of parts in any thing, *viz.* phyſical parts, metaphyſical parts, &c. ariſe ſo many different kinds of definitions of the ſame thing; thus, man is either defined an animal, conſiſting of ſoul and body; or, a reaſonable animal, &c.

Definitions are of two kinds; the one *nominal*, or, *of the name*: the other *real*, or, *of the thing*.

DEFINITION *of the name*, or *nominal* DEFINITION, is that which explains the ſenſe or ſignification appropriated to a word: or, as Wolfius more accurately conſiders it, it is an enumeration of certain marks, or characters ſufficient to diſtinguiſh the thing defined from any other thing; ſo as to leave it out of doubt, what the ſubject is that is intended, or denoted by the name. This is what is meant by definition in mathematics.

Such is the definition of a ſquare, when it is ſaid to be a quadrilateral, equilateral, rectangular figure.

By definition of the name, is either meant a declaration of the ideas and characters appropriated to the word in the common uſage of the language; or the peculiar ideas, &c. which the ſpeaker thinks fit to denote by that word, *i. e.* the ſpecial ſenſe wherein he propoſes to uſe it, in his future diſcourſe. For it may be obſerved that the ſignificancy of any word depends entirely on our will; and we may affix what idea we pleaſe to a ſound, which itſelf ſignifies nothing at all.

The definition of the name, therefore, in the ſecond ſenſe, is merely arbitrary, and ought never to be called in queſtion; only it is to be minded, that we keep inviolably to the ſame ſignification. Hence, a definition comes to ſtand, or to be made uſe of as an undoubted, or ſelf-evident maxim; as it frequently does, and particularly among geometricians, who, above all other people, make uſe of ſuch definitions.

Not that we mean, that after having defined a thing ſo and ſo, there is nothing in our idea affixed to the defined term, but muſt be granted to the thing itſelf; thus, if any one ſhould define heat to be a quality in certain bodies, like that which we feel upon the application of fire, or hot bodies; no man could find fault with the definition, as far as it expreſſes what he means by the word heat; but this does not hinder us from denying that there is any thing in the body that warms us, like what we feel in ourſelves.

DEFINITION *of the thing*, or *real* DEFINITION, is properly an enumeration of the principal attributes of a thing, in order to convey or explain its nature.

Thus, a circle is defined a figure, whoſe circumference is every where equidiſtant from its centre.

Wolfius defines a real definition to be a diſtinct notion, explaining the geneſis of a thing, that is, the manner wherein the thing is made or done; ſuch is that of a circle, whereby it is ſaid to be formed by the motion of a right line round a fixed point. On which footing, what was before inſtanced as a real definition of a circle, amounts to no more than a nominal one.

This notion of a real definition is very ſtrict and juſt; and affords a ſufficient diſtinction between a real and a nominal one. But though it has the advantages of analogy, diſtinctneſs, and conveniency on its ſide; yet, being only itſelf a nominal definition, *i. e.* a definition of the term real definition, we muſt conſider it in that light, that is, an idea fixed arbitrarily to that word, and which the author always denotes by that word in the courſe of his book. But, in effect, it is not the uſual ſenſe, or acceptation of the term; which is much leſs convenient and diſtinct. And it is to that uſual acceptation we are here chiefly to have regard.

Definitions are alſo divided into *accurate* and *inaccurate*; the firſt make what we ſtrictly call a definition; the ſecond, we diſtinguiſh under the name of *deſcription*.

Of the parts enumerated in a definition, ſome are common to other things beſide the thing defined; others are peculiar thereto: the firſt are called the *genus* or *kind*; and the ſecond the *difference*. Thus, in the former definition of a circle, by a figure, whoſe circumference is every where equidiſtant from its centre; the word *figure* is the *kind*, as being a name common to all other figures, as well as the circle; the reſt are the difference which ſpecify, or diſtinguiſh this figure from every other figure. And hence ariſes that rule of F. de Colonia, for the making of a definition. "Take," ſays he, "ſomething that is common to the thing *defined* with other things, and add to it ſomething that is proper, or peculiar to the thing; *i. e.* join the genus and ſpecific difference, and you will have a definition." Thus, *e. gr.* rhetoric is defined the art of ſpeaking well; for that it is an art, is common to it with ſeveral other things; but that it is the art of ſpeaking well, is peculiar to it alone.

There

There are five common rules of a good definition. 1. That it be clear, and more eaſy and obvious than the thing defined. 2. That it be univerſal, or adequate to the thing defined; that is, it muſt agree to all the ſpecies or individuals included under the ſame idea. 3. That it be proper or peculiar to the thing defined. The two ordinary defects of definitions are, not to agree either to the whole thing, or the ſole thing defined: neque omni, neque ſoli: than which nothing is more common, even among the beſt and juſteſt authors. 4. That it be ſhort. And 5. That neither the thing defined, nor a mere ſynonymous name, make any part of the definition.

Lord Bacon obſerves of Ariſtotle's definitions in the general, that they are very much like that, whereby man ſhould be defined an animal that tills the ground. Nor was his maſter Plato leſs exceptionable. The joke put upon him on that account is famous: Plato, it ſeems, had defined man, *animal bipes & implume*, a two-footed animal without feathers. Upon which, Diogenes the cynic, a great derider of the academics, threw a cock ſtripped of his feathers, and quite naked, into the middle of Plato's ſchool; crying, "Here is Plato's man."

Our definition of ſubſtances, it muſt be added, are very defective: and as for individuals, we have no definitions at all. The ideas of ſubſtances are compounded of the various ſimple ideas, jointly impreſſed when they preſent themſelves; and all we can do to define them, is only to enumerate thoſe ſeveral ſenſible ideas, as colour, denſity, malleability, weight, &c. Thus gold is defined by ſuch a peculiar colour, gravity, &c. Yet ſuch definitions may raiſe an idea clear enough of that ſubſtance in the mind of one who has ſeparately received, by his ſenſes, all the ſimple ideas that are in the compoſition of the complex idea defined; though the intimate nature and eſſence of ſubſtance are unknown, and conſequently cannot be defined.

It follows, that they are only the modes, or attributes, that can be explained by what we properly call a definition.

DEFINITION, in *Rhetoric*, is one of the common places, and is defined by Tully, a ſhort comprehenſive explanation of a thing.

The definitions of the orator, it muſt be obſerved, differ much from thoſe of the logician and philoſopher: theſe latter define a thing cloſely and drily by genus and difference, *e. g.* man is a reaſonable animal, &c.

The orators take a larger compaſs, and define things more ornamentally from the places of rhetoric, thus: man is a curious work of an Almighty Creator, framed after his own image, and endued with reaſon, and born for immortality. But this rhetorical definition, in ſtrictneſs, comes nearer to the nature of a deſcription than an accurate definition.

DEFINITIVE is applied to ſomewhat that terminates or decides a queſtion, or proceſs. Thus we ſay:

The houſe of lords have paſſed a definitive ſentence in ſuch a cauſe: the church has given a definitive judgment on ſuch an article of faith.

The word ſtands in oppoſition to proviſional, and interlocutory.

DEFINITIVE *Pronoun*, in *Grammar*. See DEMONSTRATIVE.

DEFINITIVES, denote, according to the arrangement of Mr. Harris, one of the four ſpecies of words; or ſuch as are ſignificant by relation, called by others articles. See ARTICLE.

DEFINITOR, a term uſed in ſeveral religious orders, for an aſſeſſor, or counſellor of a general, or ſuperior in certain monaſteries.

In moſt orders of religious, the definitor takes place after the ſuperior of the convent he lives in, when in the convent itſelf; but out of the convent, the definitor's place is before his own ſuperior.

Definitors are alſo ſubject in the convent where they reſide, to the immediate ſuperior of the convent, as to things relating to the monaſtic diſcipline, but in nothing elſe.

DEFLAGRATION, in *Chemiſtry*, is uſually applied to any rapid combuſtion ſpreading through any mixture accompanied with much evolution of flame and vapour. Thus nitre deflagrates when thrown on hot coals, or mixed with charcoal and fired. When accompanied with a loud noiſe it is termed *detonation*.

DEFLECTION, the turning any thing aſide from its former courſe, by ſome adventitious or external cauſe.

The word is often applied to the tendency of a ſhip from her true courſe, by reaſon of currents, &c. which divert her, and turn her out of her right way.

DEFLECTION *of light*. See INFLECTION *of light*.

DEFLECTIVE FORCES, (from *deflecto*, Latin, to bend, to turn aſide,) are thoſe forces which act upon a moving body in a direction different from that of its actual courſe, in conſequence of which the moving body is deflected from its original courſe, *viz.* is obliged to deviate from that direction in which it would move if not acted upon by any of thoſe forces. Thus a ball projecting horizontally from a cannon, would move in a ſtraight line if the force of gravity did not deflect it from that direction. See CENTRAL, or CENTRIPETAL, and CENTRIFUGAL *forces*.

DEFLORATION, or DEFLOWERING, the act of violating or taking away a woman's virginity.

Death, or marriage, are decreed by the civil law in caſe of defloration. Many anatomiſts make the hymen a real proof of virginity, perſuaded that where it is not found, the girl muſt have been deflowered. See HYMEN.

The ancients had ſo much reſpect for virgins, that they would not put them to death, till they had firſt procured them to be deflowered. On the contrary the natives of the coaſt of Malabar hold virginity in ſo little eſtimation, that they pay ſtrangers to come and deflower their brides. Among the Scots, it was a privilege of the lords of the manor, that they ſhould have the firſt night's lodging with their tenant's wives. King Malcolm III. allowed the tenants to redeem this ſervice at a certain rate, called marcheta, conſiſting of a certain number of cows. Buchanan ſays, it was redeemed with half a mark of ſilver. The ſame cuſtom had place alſo in Wales, Flanders, Frieſland, and ſome parts of Germany. See BOROUGH-ENGLISH.

By the cuſtom of Anjou and Maine, a maid, after twenty-five years of age, may ſuffer herſelf to be deflowered, without being diſinherited for it by her father.

Du-Cange quotes an arret of the nineteenth of March, 1409, obtained by the inhabitants of Abbeville, againſt the biſhop of Amiens, for taking money to diſpenſe with an injunction he had made, not to ſuffer them to conſummate their marriage the three firſt nights; the injunction being founded on a canon of the fourth council of Carthage, which decrees the ſame, out of reverence of the matrimonial benediction.

DEFLUVIUM, is uſed to expreſs a diſtemper in trees, whereby they loſe their bark; it is thought to be cauſed by a ſharp humour, that diſſolves the glue whereby the bark is faſtened to the wood, and ſometimes by too much drought.

DEFLUXION, in *Medicine*, from *defluo*, *I flow down*, a term uſed by the older writers to denote an increaſed diſcharge of fluids from any particular part, as from the noſtrils, in *coryza*, and from the trachea and bronchial paſſages in-

in *catarrh*, with which the word is ſynonymous. It was originally uſed, it would ſeem, to expreſs the collection of humours in the part, which were ſuppoſed to *flow down* to it from ſome other part. Thus Celſus conſiders the diſorders, juſt named, as occaſioned by a *defluxion* of humours from the head to the noſe, throat, and lungs reſpectively, lib. iv. cap. 4. de Medicina. Almoſt every inflamed part was conſidered as the ſeat of a defluxion of this kind; the morbid ſecretions, which were the conſequence and production of the inflammatory action of the veſſels of the part, being ſuppoſed to be the cauſe of the diſorder. See CONCOCTION and CATARRH. Hence the truth of ſome of the ancient prognoſtic aphoriſms; as when it is affirmed, that defluxions on the lungs are dangerous, theſe defluxions including peripneumony and pulmonary conſumption; and that defluxions on the eyes, that is, ophthalmia in its various forms, occaſion weakneſs of ſight and often blindneſs.

DE-FOE, DANIEL, in *Biography*, the ſon of James Foe, a butcher by trade, was born about the year 1663, and it is by no means fairly aſcertained why Daniel aſſumed the prefix De to his family name. He was educated at Newington Green, and exhibited an early taſte for literature. As an author, he publiſhed, before he had attained the age of manhood, a political pamphlet; and diſplayed his regard to the cauſe of liberty and the Proteſtant religion by joining the inſurrection of the duke of Monmouth, but by a happy addreſs he eſcaped to the metropolis unnoticed. In the way of trade, he was unſucceſsful, and became inſolvent, but to his honour, it muſt be recorded, that after he had been legally freed from his debts, by a compoſition, he paid moſt of them upon a fortunate change of circumſtances. He had the ambition of being an inventor, and publiſhed an octavo volume, entitled, "An Eſſay on Projects." In the year 1701, he publiſhed "The true-born Engliſhman," a ſatire which excited a conſiderable ſhare of attention. The object of this work was to reply to thoſe who were perpetually abuſing king William and his friends as foreigners, by ſhewing that the then exiſting race of Engliſhmen was ſo mixed and heterogeneous, as to be able to lay claim to no native purity of blood. One of his next pieces was a ſatire, entitled "Reformation of Manners," which contains, among other things, an invective againſt the ſlave trade. He is ſuppoſed to have been the writer of "A Memorial to the Houſe of Commons," uſually denominated the "Legion Letter," which is a manly and ſpirited cenſure of the conduct of that aſſembly in reference to the Kentiſh petition. In the year 1702, when the high church party was inclined to perſecute the diſſenters, De-Foe publiſhed "The ſhorteſt Way with the Diſſenters, or Propoſals for the Eſtabliſhment of the Church." For this he was tried and convicted, and was ſentenced to fine, impriſonment, and the pillory. No part of the judgment was mitigated, and ſo far from being aſhamed of his fate, he wrote "A Hymn to the Pillory." During his impriſonment he publiſhed a periodical work, entitled "The Review," which contained the news of the day, and is ſaid to have given the hint of the Tatler, and the other celebrated papers of Steele and Addiſon. He did not finiſh the period of his impriſonment in Newgate, but was liberated at the interceſſion of Harley, afterwards earl of Oxford, and the queen herſelf afforded aſſiſtance to him and his family. Soon after his liberation he publiſhed, by ſubſcription, his "Jure divino" in 12 books, the object of which was to expoſe the doctrine of the divine right of kings, and to decry tyranny. By the government he was employed in aiding the union with Scotland, and after the important meaſure was completed, he drew up and publiſhed a hiſtory of it in folio. De-Foe thought his great fort was irony, and in many inſtances it muſt be acknowledged that he was ſucceſsful; but on the acceſſion of the houſe of Hanover, he made uſe of the ſame weapon ſo very awkwardly that his publications were taken for libels in favour of the pretender, and he was tried and impriſoned on their account. About the year 1715, he commenced a new ſtyle of writing, and publiſhed "The Family Inſtructor," which has been highly regarded for its excellent moral tendency. But the moſt diſtinguiſhed of the works of Daniel De-Foe is, "The Life and Adventures of Robinſon Cruſoe," which was firſt publiſhed in 1719. This work is too well known to every Engliſh reader to ſtand in need of being characteriſed here. It has paſſed through as many editions as almoſt any book in our language of the ſame ſtanding, and muſt long continue to be the favourite book in the juvenile library. "Religious Courtſhip" is another of Mr. De-Foe's works, which is of a tendency very ſimilar to that of his "Family Inſtructor." He could unite the ſerious and the gay with admirable effect; "A Journal of the plague Year," though a fiction, was written in ſo very natural and intereſting a manner, that it was taken by Dr. Mead for real hiſtory. Beſides the works already mentioned, De-Foe was the author of many others, of which an account is given in the Biographia Britannica. He died on the 26th of April, 1731, in the pariſh of St. Giles's, Cripplegate, leaving behind him a widow and ſeveral children. De-Foe poſſeſſed much merit as a citizen, and as a writer. His proſe works are much more valuable than his poetical performances. As a political writer, he had great merit; his ſentiments appear to have been generally juſt, and he expreſſed himſelf with force and perſpicuity. His pieces on the ſubject of trade and commerce, place him in the foremoſt rank among his contemporaries. "Were we," ſays his biographer, "to compare De-Foe with Davenant, it would be found that Davenant has more detail from official documents; that De-Foe has more facts from wider inquiry. Davenant is more apt to conſider laws in their particular application; De-Foe more frequently inveſtigates commercial legiſlation in its general effects. From the publications of Davenant it is ſufficiently clear, that he was not very regardful of the means, nor very attentive to the conſequences; De-Foe is more correct in his motives, and more ſalutary in his ends." Biog. Brit.

DEFOLIATA. See DECIDUOUS and LEAF.

DEFORCEMENT, in *Law*, a withholding lands or tenements, by force, from the right owner. (Co. Litt. 277) In this extenſive ſenſe it includes an abatement, an intruſion, a diſſeiſin, or a diſcontinuance, as well as any other ſpecies of wrong, whereby he that hath a right to the freehold is kept out of poſſeſſion. But as contradiſtinguiſhed from theſe, it is only ſuch a detainer of the freehold, from him that hath the right of property, but never had any poſſeſſion under that right, as falls not under any of thoſe terms. As in caſe where a lord has ſeignory, and lands eſcheat to him *propter defectum ſanguinis*, but the ſeiſin of the lands is withheld from him; here the injury is not *abatement*, for the right veſts not in the lord as heir or deviſee; nor is it *intruſion*, for it veſts not in him who hath the remainder or reverſion; nor is it *diſſeiſin*, for the lord was never ſeized; nor does it at all bear the nature of any ſpecies of *diſcontinuance*; and it muſt, therefore, be a *deforcement*. (F. N. B. 143.) If a man marries a woman, and, during the coverture, is ſeized of lands, and alienes, and dies; is diſſeiſed and dies; or dies in poſſeſſion; and the alienee, diſſeiſor, or heir, enters on the tenements, and doth not aſſign the widow her dower; this is alſo a deforcement to the widow, by withholding lands to which ſhe hath a right. (F. N. B. 147.) In like manner, if a man

leaſe

leaſe lands to another for a term of years, or for the life of a third perſon, and the term expires by ſurrender, efflux of time, or death of the *ceſtuy que vie;* and the leſſee, or any ſtranger, who was, at the expiration of the term, in poſſeſſion, holds over, and refuſes to deliver the poſſeſſion to him in remainder or reverſion, this is likewiſe a deforcement. (Finch. L. 263. F. N. B. 201—5, 6, 7.) Deforcements may alſo ariſe upon the breach of a condition in law; as if a woman gives lands to a man by deed, to the intent that he marry her, and he will not when thereunto required, but continues to hold the lands; this is ſuch a fraud on the man's part, that the law will not allow it to diveſt the woman's right of poſſeſſion; though, his entry being lawful, it does diveſt the actual poſſeſſion, and thereby becomes a deforcement. (F. N. B. 205.) Deforcements may be alſo grounded on the diſability of the party deforced; as if an infant makes an alienation of his lands, and the alienee enters, and keeps poſſeſſion; now, as the alienation is voidable, this poſſeſſion as againſt the infant (or, in caſe of his deceaſe, as againſt his heir) is, after avoidance, wrongful, and, therefore, a deforcement. (Finch. L. 264. F. N. B. 192.) The ſame happens, when one of non-ſane memory alienes his lands or tenements, and the alienee enters and holds poſſeſſion, this may alſo be a deforcement. (Finch. L. 264. F. N. B. 202.) Another ſpecies of deforcement is, where two perſons have the ſame title to land, and one of them enters and keeps poſſeſſion againſt the other; as where the anceſtor dies poſſeſſed of an eſtate in fee-ſimple, which deſcends to two ſiſters as coparceners, and one of them enters before the other, and will not ſuffer her ſiſter to enter and enjoy her moiety; this is alſo a deforcement. (Finch. L. 293, 294. F. N. B. 197.) Deforcement may be alſo grounded on the non-performance of a covenant-real; as if a man ſeiſed of lands, covenants to convey them to another, and neglects or refuſes ſo to do, but continues poſſeſſion againſt him; this poſſeſſion, being wrongful, is a deforcement (F. N. B. 146.); whence, in levying a fine of lands, the perſon, againſt whom the fictitious action is brought upon a ſuppoſed breach of covenant, is called the deforciant. And, laſtly, by way of analogy, keeping a man by any means out of a freehold office is conſtrued to be a deforcement; though, being an incorporeal hereditament, the deforciant has no corporeal poſſeſſion. So that whatever injurious withholding the poſſeſſion of a freehold is not included under *abatement, intruſion, diſſeiſin,* or *diſcontinuance,* is compriſed under *deforcement.* Blackſt. Com. vol. iii. p. 174.

DEFORCEMENT, in the law of Scotland, is uſed for the reſiſting, or offering violence to the officers of the law, while they are actually employed in the exerciſe of their functions, by putting its order and ſentences in execution; whether they be officers of the ſupreme courts of juſtice, as heralds, purſuivants, meſſengers, macers; or of inferior courts, as mayors.

The puniſhment of this crime is confiſcation of moveables, joined with ſome arbitrary puniſhment; as fine, impriſonment, baniſhment, or corporal pains, according to the degree of violence, and other circumſtances which aggravate the crime; beſides, the party aggrieved may have an action of damages, to be highly taxed out of the firſt and readieſt of the offender's eſcheat, or other eſtate. See Bayne's Criminal Law.

Deforcing of officers of the cuſtom-houſe, is provided againſt by the ſame ſtatutes as in England.

DEFORCER, or DEFORCIANT, one that caſts out another from his lands, or tenements, by mere force. See DEFORCEMENT.

DEFORMITY is immediately oppoſed to beauty, and denotes the want of that uniformity, ſymmetry, and variety neceſſary to conſtitute beauty. Accordingly, Dr. Hutcheſon defines it by the abſence of beauty, or a deficiency in the beauty expected in any ſpecies. Deformity and beauty may be conſidered either as natural or moral. Theſe are both referred by the above-mentioned ingenious writer to an internal ſenſe, and our perceptions of them, as he ſuppoſes, ariſe from an original arbitrary ſtructure of our own minds, by which certain objects, when obſerved, are rendered the occaſions of certain ſenſations and affections.

That many objects give no pleaſure to our ſenſe, is obvious. Many are certainly void of beauty; but then, ſays this author, there is no form which ſeems neceſſarily diſagreeable of itſelf, when we dread no other evil from it, and compare it with nothing better of the kind. Many objects are naturally diſpleaſing, and diſtaſteful to our external ſenſes, as well as others pleaſing and agreeable; as ſmells, taſtes, and ſome ſeparate ſounds: but with regard to our ſenſe of beauty, no compoſition of objects which give not unpleaſant ſimple ideas, ſeems poſitively unpleaſant, or painful of itſelf, had we never obſerved any thing better of the ſame kind.

Had there been a ſpecies of the form which we now denominate ugly, or deformed, and had we never ſeen or expected greater beauty, we ſhould have received no diſguſt from it; though the pleaſure would not have been ſo great in this form as in thoſe we now admire. Our ſenſe of beauty ſeems deſigned to give us poſitive pleaſure; but not poſitive pain or diſguſt, any farther than what ariſes from diſappointment.

There are, indeed, many faces which, at firſt view, are apt to raiſe diſlike. But this is generally not from any poſitive deformity, but either from want of expected beauty, or from the carrying ſome natural indications of morally bad diſpoſitions, which we all acquire a faculty of diſcerning in countenances, airs, and geſtures. That this is not occaſioned by any form poſitively diſguſting, appears hence, that if, upon long acquaintance, we are ſure of finding ſweetneſs of temper, humanity, and cheerfulneſs, though the bodily form continues, it ſhall give us no diſguſt. There are horrors raiſed by ſome objects, which are only the effect of fear for ourſelves, or compaſſion towards others, when either reaſon, or ſome fooliſh aſſociation of ideas, makes us apprehend danger, and not the effect of any thing in the form itſelf. For we find that moſt of thoſe objects, which excite horror at firſt, when experience or reaſon has removed the fear, may become the occaſion of pleaſure.

The caſual conjunction of ideas gives us diſguſt, where there is nothing diſagreeable in the form itſelf. And this, in effect, is the cauſe of moſt of our fantaſtic averſions to the figures of diverſe animals, &c. Thus, ſerpents of all kinds, and many inſects, really beautiful enough, are beheld with averſion by many people, who have got ſome accidental ideas of miſchief aſſociated to them. A ſimilar reaſoning is applied to our perception of moral beauty and deformity. Inquiry into the Original of our Ideas of Beauty and Virtue, paſſim.

But it is more juſt to diſtinguiſh between the ſentiments of delight or diſguſt, excited in us by beautiful or deformed objects, which are effects of ſome cauſes, and the natural and real qualities of the perceived objects by which they are produced. There are objects, ſays an excellent writer, which have a natural aptitude to pleaſe or offend, or between which and the contemplating mind there is a neceſſary congruity or incongruity; and though the actual perception of the underſtanding, and conſequent feeling of the heart, in contemplating

contemplating the actions and affections of moral agents may exiſt in very different degrees, on account of the incidental obſtructions, ariſing from bodily indiſpoſition, mental prejudices and biaſſes, and the aſſociation of ideas; yet, to every rational mind properly diſpoſed, morally good actions muſt for ever be acceptable, and can never, of themſelves offend; and morally evil actions muſt for ever be diſagreeable, and can never of themſelves pleaſe. What is right in actions and characters is beautiful and amiable, and gives pleaſure; what is wrong is deformed and odious, and excites diſguſt: right and pleaſure, wrong and pain, are as diſtinct as cauſe and effect. It is no leſs abſurd to maintain, that the perception of virtue is nothing diſtinct from the reception of the pleaſure reſulting from it, than to infer, with ſome metaphyſicians, that ſolidity, extenſion, and figure, are only particular modes of ſenſation, becauſe attended whenever they are perceived with ſome ſenſations of ſight or touch. Thus does this author ſhew, that moral beauty and deformity are real qualites of certain actions; in which conſiſts their aptitude to pleaſe or diſguſt. With reſpect to natural beauty, he obſerves, that uniformity amidſt variety pleaſes, becauſe of the natures of variety and uniformity, which are ſuch, that, whenever united, they are adapted to pleaſe every free unbiaſſed mind that diſcerns them. He accounts for the pleaſure they afford, without referring them to an arbitrary, internal ſenſe, by the following circumſtances that attend them. They are more eaſily comprehended by the mind: order and ſymmetry give things their ſtability and ſtrength, and ſubſerviency to any valuable purpoſe; regularity and order evidence art and deſign. Diſorder and confuſion, whence deformity ariſes, denote only the negation of regularity and order; or any arrangement and diſpoſition of things, which are not according to a law, rule, or plan, and prove not deſign. Theſe are not poſitively diſpleaſing; except where we previouſly expected order, or where impotence or want of ſkill appear, and the contriver has either failed of his deſign, or executed it ill. See on this ſubject Dr. Price's Review of the principal Queſtions and Difficulties in Morals, ch. ii. paſſim. See an admirable Eſſay on Bodily Deformity, by Mr. Hay, in the Fugitive Pieces, vol. i. p. 93, &c. See BEAUTY.

DEFOSSION, *Defoſſio*, the puniſhment of burying alive, inflicted, among the Romans, on Veſtal virgins guilty of incontinency. It is alſo a cuſtom among the Hungarians to inflict this puniſhment on women convicted of adultery. Heretics alſo were puniſhed in this manner. See BURIAL.

DEFTARDAR, or DEFTERDAR, or *Teſterdar-eſſendi*, the treaſurer of the revenues of the Turkiſh empire, or the miniſter of the finances.

The word is compounded, firſt, of *defter*, a Turkiſh name for a book, regiſter, memoir, &c. which Meninſki derives from the Greek διφθερα, the ſkin or parchment anciently wrote on. The ſecond word, whereof deftardar is compounded, is *dar*, a Turkiſh and Perſian word, ſignifying *keeping* or *holding*, *q. d.* book-keeper of the monies received and expended.

Meninſki calls him *ſupremus theſaurarius*, high treaſurer; and *præſes cameræ*, preſident of the exchequer. Caſtellus makes him the keeper and comptroller of the books of receipts and payments.

The deftardar, or, as Vigenere calls him, dephterderi, has in his charge the rolls and accounts of the militia, and the treaſury: he receives all the grand ſignior's revenues, pays his forces, and furniſhes the expences of all public affairs: in which his office differs from that of khaſné-veliki, a black eunuch, who is charged with the general adminiſtration of the interior imperial treaſure, into which is poured the produce of the confiſcations and inheritances that ſerve for the ſupport of the ſeraglio. The preſents, the effects, the jewels which are ſent by foreign powers, thoſe acquired by conqueſt, the colonies, &c. conſtitute a part of this treaſure. This treaſurer or miniſter of the finances is alſo different from the chaznadar or khaſnadar-aga, who is one of the pages of confidence, and adminiſters the private treaſure of the ſultan, as the others do thoſe of the ſtate and of the ſeraglio. The ſultan's private treaſure, increaſed by the ſavings of the greater number of the ſultans, is ſupported by the profits of the mint, and by ſome confiſcations. The treaſure under the management of the teſterdar-eſſendi conſiſts of the produce of the ſale of the great employments, of that which ariſes from the annual renewal of the barats or firmans, obtained by the zaïms, timariots, and others, the produce of the karatch or capitation-tax on the Jews and Chriſtians, the produce of the farmed domains, that of the cuſtoms, &c. &c.

Ricaut makes a deſtardar, whom he calls teſtardar, in each beglerbeglic, or government. Vigenere aſſures us, there are but two, the one for Europe, and the other for Aſia; the firſt reſides at Conſtantinople, and has under him two general commiſſioners, or deputies, one for Hungary, Tranſylvania, Walachia, Croatia, Servia, Bulgaria, Boſnia, &c. the other for Greece and the Morea, with the iſlands of the Archipelago.

Each of theſe has under him as many ſub-commiſſioners, or agents, as there are ſangiackats in his province; which ſub-commiſſioners have as many clerks as there are aſbaſſis in their ſangiackat, to keep the account of the timariots in their diſtricts. The deſtarder of Aſia has two general deputies, the one for Anatolia; the other for Syria, Arabia, and Egypt: theſe have likewiſe their ſub-agents, clerks, &c. as thoſe of Europe.

DEGAGNAC, in *Geography*, a town of France, in the department of the Lot; $4\frac{1}{2}$ leagues N. of Cahors.

DEGENERATION, the act of failing, or declining from a more perfect, or valuable kind, ſtate, or condition, to an inferior or worſe.

M. Buffon is a ſtrenuous advocate for the degeneration of animals, and he aſcribes it to three cauſes, *viz.* the temperature of the climate, the quality of the food, and the evils produced by ſlavery. Whenever man, he ſays, began to change his climate, and to migrate from one country to another, his nature became ſubject to various alterations, which were greater or leſs in proportion to the diſtance of his removal from the ſituation which he originally occupied. During the lapſe of ages, and after he had traverſed whole continents, intermixing with thoſe who had already degenerated under the influence of different climates; after he was habituated to the ſcorching heats of the ſouth, and the frozen regions of the north; he underwent changes ſo conſiderable and ſo conſpicuous as to furniſh occaſion for ſuſpecting, that the Negro, the Laplander, and the White, were really different ſpecies, if we were not previouſly aſſured, on the one hand, that one man only was originally created, and, on the other, that the White, the Laplander, and the Negro, are capable of uniting and of propagating the great and undivided family of the human kind. Hence he concludes, that thoſe marks which diſtinguiſh men who inhabit different regions of the earth are not original, but purely ſuperficial. It is the ſame identical being, who is varniſhed with black under the torrid zone, and tawned and contracted by extreme cold under the polar circle. Man, he ſays, is the ſame in both the two great continents into which the earth is divided. The Aſiatic, the European,

and the Negro, produce equally with the American; nor can any thing, as this ingenious writer maintains, be a ſtronger proof that they belong to the ſame family than the facility with which they unite to the common ſtock. The blood is different, but the germ is the ſame. The ſkin, the hair, the features, and the ſtature, have varied, without any change in the internal ſtructure. The type is general and common; and if, by any great revolution, man was forced to abandon thoſe climates which he had invaded, and to return to his native country, he would, in the progreſs of time, reſume his original features, his primitive ſtature, and his natural colour. But this effect would be produced much ſooner by the mixture of races. A white male with a black female, or a black male with a white female, equally produce a mulatto, whoſe colour is brown, or a mixture of black and white. This mulatto, intermixing with a white, produces a ſecond mulatto leſs brown than the former; and if the ſecond mulatto unites with a white, the third will only have a ſlight ſhade of brown, which will entirely vaniſh in future generations. Hence, by this mixture, 150 or 200 years are ſufficient to bleach the ſkin of a Negro. The influence of climate produces this change by ſlow degrees, and in a ſeries of ſeveral centuries; but great as this alteration is, it is only ſuperficial. The colour of the ſkin, hair, and eyes, varies by the influence of climate alone. The other changes, ſuch as thoſe of ſtature, figure, features, and quality of the hair, ſeem to require the joint operations of climate and other cauſes. The moſt direct and general of theſe concurring cauſes is the quality of the food. It is chiefly by aliment that man receives the influence of the ſoil which he inhabits; whilſt that of the air and climate acts more ſuperficially. While the climate changes the colour of the ſkin, food acts upon the internal form by its qualities, which are always related to thoſe of the earth by which it is produced. In the ſame country we perceive ſtriking differences between thoſe who occupy the heights and thoſe who inhabit the low grounds. The inhabitants of the mountains are always better made, more lively, and more beautiful, than thoſe of the valley. Hence, in countries remote from the original climate, where the herbs, fruits, grains, and the fleſh of animals, differ both in quality and ſubſtance, the men who feed upon theſe articles muſt, in a courſe of years, undergo ſtill greater changes. But it requires ages, in the conſtant uſe of the ſame food, to change the features, the ſize of the body, and the ſubſtance of the hair, and to produce thoſe internal alterations, which, when perpetuated by generation, become general and permanent characteriſtics which diſtinguiſh the different races and nations that compoſe the aggregate of the human ſpecies.

With regard to brute animals, theſe effects are greater and more ſuddenly accompliſhed; becauſe they are more nearly allied to the earth than man; becauſe their food, more uniformly the ſame, and ſubject to no preparation, has qualities more determinate and of more powerful influence; and becauſe the animals, being unable to clothe themſelves, or to uſe the element of fire, operations which require the ſkill of man, remain perpetually expoſed to the action of the air, and all the inclemencies of the climate. Animals are more fixed in their habitation than man, and continue for a longer interval of time in ſituations that are beſt adapted to their conſtitution. But when they are forced by men, or by any revolution on the globe, to abandon their native ſoil, their nature undergoes changes ſo great, that, in order to recognize them, recourſe muſt be had to accurate examination, and even to experiment and analogy. If to theſe natural cauſes of alteration in free animals, we add that of the empire of man over thoſe which he has reduced to ſlavery, we ſhall be aſtoniſhed at the degree to which tyranny can degrade and diſfigure nature; we ſhall perceive the marks of ſlavery, and the prints of her chains; and we ſhall find, that theſe wounds are deeper and more incurable in proportion to their antiquity; and that, in the preſent condition of domeſtic animals, it is perhaps impoſſible to reſtore their primitive form, and thoſe attributes of nature of which we have deprived them.

M. Buffon examines, in detail, the operation and effect of the cauſes above-ſpecified, and, by ſo doing, exhibits a picture of nature in her preſent condition contraſted againſt what he conceives it to have been before her degradation. The firſt animal, which he contemplates in its original ſtate and in that of its degeneration, is the ſheep, compared with the mouflon, from which the modern animal derives its origin. The mouflon, ſays this author, is a large, ſwift, ſtrong animal, armed with horns and thick hoofs, covered with coarſe hair, and dreading neither the inclemency of the ſky nor the voracity of the wolf. How different from our ſheep, who ſubſiſt with difficulty in flocks, who are unable to defend themſelves by their number, who cannot endure the cold of our winters without ſhelter, and who would all periſh, if man withdrew his protection! Timidity, weakneſs, reſignation, and ſtupidity, are the only melancholy remains of their degraded nature. To obtain fine wool, ſays this ingenious writer, our rams ſhould have Barbary ewes; and to augment the ſize, our ewes ſhould be ſerved with the male mouflon. Our goats might be managed in the ſame manner. By intermixing them with the goat of Angora, their hair might be changed, and rendered equally uſeful as the fineſt wool. In our climate the ſpecies of the goat is not ſo much degenerated as that of the ſheep. It appears to be ſtill more degenerated in the warm countries of Africa and India. The ſpecies of the ox is more influenced by nouriſhment than that of any other domeſtic animal. The influence of food is in general greater, and produces more ſenſible effects upon ſuch animals as feed on herbs or fruits. Carnivorous animals, on the contrary, are leſs affected by this cauſe than by the influence of climate; becauſe fleſh is an aliment already aſſimilated to the nature of the animal by which it is devoured; but graſs is the firſt product of the ſoil, and has all the properties of it; and theſe terreſtrial qualities are immediately communicated to the animal. Accordingly the dog ſpecies, upon which food ſeems to have a very ſlight influence, is more varied than that of any other carnivorous animal. In his degradations, he ſeems to follow exactly the differences of climate. In the warmeſt climates he is naked, covered with a coarſe thick hair in the northern regions, and adorned with a fine ſilky robe in Spain and in Syria, where the mild temperature of the air converts the hair of moſt animals into a kind of ſilk. But independently of the external varieties produced by the influence of climate, the dog is ſubject to other changes, which proceed from his ſituation, his captivity, or the nature of the intercourſe he holds with man. Of all the varieties of dogs, the ſhepherd's dog ſeems to be the leaſt degenerated; and he is likewiſe the moſt uſeful for guarding our flocks, and for the preſervation of good order. His race ought, therefore, to be more multiplied than thoſe of other dogs, who miniſter only to our amuſements, and whoſe number is ſo great that, in every town and village, the proviſions conſumed by them would nouriſh many families. The domeſtic ſtate has greatly contributed to vary the colour of animals, which, in general, was originally brown or black. The dog, the ox, the goat, the ſheep, the horſe, have aſſumed all kinds of colours. The dog has changed from black to white; and pure white, without any ſpots, ſeems to mark the laſt de-

gree of degeneration, and is generally accompanied with eſſential imperfections. All quadrupeds which are abſolutely white have thoſe faults of dullneſs of hearing and red eyes, which are obſervable in the race of white men. This kind of degeneration, though more frequent among domeſtic animals, ſometimes appears among the wild ſpecies, as in thoſe of the elephant, ſtags, fallow-deer, monkeys, moles, and mice; in all which this colour is uniformly accompanied with ſmaller or greater degrees of bodily weakneſs, and bluntneſs of the ſenſes. But ſlavery ſeems to have made the deepeſt and moſt conſpicuous impreſſions on the camel. He is brought forth with bunches on his back, and calloſities on his breaſt and knees. The wild animals, not being under the immediate dominion of man, are not ſubject to ſuch great changes as the domeſtic kinds. Their nature ſeems to vary with different climates; but it is no where degraded. If they were capable of chuſing their climate and their food, the changes they undergo would be ſtill leſs: but as they have at all times been hunted and baniſhed by man, and even by the ſtrongeſt and moſt ferocious quadrupeds, moſt of them have been obliged to abandon their native country, and to occupy lands leſs friendly to their conſtitution. The aſs, though ſubjected to the preſſure of the moſt wretched ſervitude, has undergone few changes; for his nature is ſo obdurate, that it equally reſiſts bad treatment and the inconveniences of a foreign climate and of coarſe food. The elephant is the only quadruped upon which the domeſtic ſtate has had no influence; becauſe, in this ſtate, he refuſes to propagate, and, of courſe, does not tranſmit to his ſpecies the blemiſhes or defects occaſioned by his unnatural condition.

Having ſurveyed the variations peculiar to each ſpecies, M. Buffon directs his attention to the moſt important change of the ſpecies themſelves. This, he ſays, is the moſt ancient degeneration; and it ſeems to have taken place in each family, or in each genus, under which the contiguous ſpecies may be comprehended. By comparing all the quadrupeds, and ranking each under its own genus, this author concludes, that the 200 ſpecies, whoſe hiſtory he has given, may be reduced to a ſmall number of families or principal ſtems, from which all the others have probably derived their origin. All the animals common to both continents, and all thoſe which are peculiar to the Old World, are reduced, by this author, to fifteen genera, and nine ſolitary or detached ſpecies; which he enumerates. Of theſe, ſeven genera and two ſpecies, *viz.* the bear and mole, are common to both continents; and hence he infers, that there remain only eight genera and fifty detached ſpecies, which are peculiar to the Old World. By purſuing the inveſtigation, and enumerating the animals peculiar to the New World, he finds, that there are about fifteen different ſpecies, which may be reduced to ten genera, and four detached ſpecies. Theſe, though they differ from the animals of the Old Continent, have remote relations which ſeem to indicate ſomething common in their formation, and lead us to cauſes of degeneration more ancient, perhaps, than all the others. Accordingly he ſuppoſes, that all the animals of the New World are much ſmaller than thoſe of the Old. This great diminution in magnitude, whatever be the cauſe of it, is a primary kind of degeneration, which could not happen without having a conſiderable influence on the figure of all theſe animals; and in comparing them, we muſt not loſe ſight of this firſt effect. For further particulars we muſt refer to the author himſelf, and to the article CLIMATE in this dictionary.

DEGENERATION *of Plants*, in *Botany*. See PLANTS.

DEGLIGI, in *Geography*, a town of the iſland of Ceylon; 16 miles N.E. of Candy.

DEGLUTITION, in *Phyſiology*, is the act of ſwallowing; or the paſſage of the food, after its maſtication has been performed in the mouth, into the ſtomach.

Moſt animals take their food into the mouth by means of the jaws themſelves; for very few poſſeſs hands. Hence the jaws are much longer in almoſt every quadruped than in man, and are continued, in an elongated and ſlender form, beyond the reſt of the head, to admit of the mouth being opened more widely, and of the food being ſeized more conveniently. They draw in fluids by the action of the tongue, previouſly rendered concave for that purpoſe.

The hands are uſed, in the human ſubject, for introducing both ſolids and fluids into the mouth; although the latter can be taken in by means of ſuction. The harder ſubſtances, being introduced into the mouth in maſſes, which are either too large for ſwallowing, or which would be unfit for the action of the ſtomach in a ſtate of aggregation, are reduced into ſmaller portions, and into a ſofter conſiſtence, by the proceſs of chewing or maſtication. Even the fluid aliments, which do not require this reduction, have to paſs from the mouth to the throat, and require, therefore, the action of particular organs deſtined for their propulſion.

The proceſs of chewing, being a neceſſary preliminary to the act of ſwallowing, will be conſidered in the firſt place. The immediate agents in this function are the two rows of teeth, implanted in the alveolar portions of the upper and lower jaw-bones, acting on the food by means of the motions of the lower jaw; and aſſiſted in their office by the lips, cheeks, and tongue. For the deſcription of the teeth, and of the bones which form the joint of the lower jaw, the reader is referred to the article CRANIUM. Our obſervations on the remainder of the ſubject will include, 1ſt, A deſcription of the joint of the lower jaw; 2dly, An explanation of its motions; and, 3dly, A deſcription of the muſcles which move it. The *mouth*, or cavity in which the act of chewing is performed, will form the next diviſion of the article: and here we ſhall give a deſcription, 1ſt, of the mouth in general; 2dly, of the lips and cheeks, with their muſcles; 3dly, of the palate, ſoft palate, and its muſcles; 4thly, of the tongue and its muſcles, including the os hyoides and the hyoidal muſcles; 5thly, of the ſalivary glands, and other glandular apparatus of the mouth, furniſhing the fluids that ſoften and dilute the food during its maſtication; 6thly, of the paſſage from the mouth into the pharynx, and the propulſion of the food through that opening. The laſt named membranous bag, which receives the food, and drives it downwards to the ſtomach, will form the third part of the article; which will be concluded with an account of the œſophagus, that conveys the food from the pharynx into the ſtomach.

Joint of the lower Jaw.—This articulation is formed between the glenoid cavity and eminentia articularis of the temporal bone on one ſide, and the condyle of the lower jaw on the other. The oppoſed ſurfaces are furniſhed with two thin cartilaginous coverings, of which one is common to the articular eminence of the temporal bone, with that portion of the glenoid cavity which is in front of the fiſſura Glaſeri; and the other belongs to the condyle. The bones are held together by three ligaments; and the joint poſſeſſes alſo a ſynovial membrane, and an interarticular cartilage. The external ligament ariſes from the root of the zygomatic proceſs of the temporal bone, deſcends obliquely backwards, and is attached to the outer part of the neck of the condyle. It conſiſts of cloſely united parallel ſhining fibres, and adheres firmly to the capſule and interarticular cartilage. The internal ligament, which is not ſo ſtrong and diſtinct as the former, is continued obliquely downwards and forwards, from the ſpinous proceſs of the ſphenoid bone to the orifice of

of the canal of the lower jaw. The ſtylo-maxillary ligament can ſcarcely be conſidered as having any concern with the articulation. It is a thin and ſmall aponeurotic chord, extended from the ſtyloid proceſs to the angle of the lower jaw, where it is fixed between the inſertions of the maſſeter and pterygoideus internus. The ſtyloglofſus muſcle is attached to a conſiderable length of this ligament. The ſynovial membrane, or capſule of the joint, conſiſts of two parts, which cannot indeed be very clearly diſtinguiſhed from each other. The ſuperior diviſion covers the articular eminence, and the upper ſurface of the articular cartilage; and is continued from one of theſe parts to the other, at the circumference of each. The lower diviſion covers the inferior ſurface of the cartilage, and is reflected from its margin to the condyle, being continued lower down on the poſterior than on the anterior ſurface of the laſt-mentioned eminence. Thus the joint of the lower jaw conſiſts of two cloſed cavities, having no communication with each other. The ſynovial membranes, which form theſe bags, are looſe where they are reflected from the articular cartilage to the bones, particularly on the anterior and poſterior aſpects of the joints, and are covered by cellular ſubſtance. There is a ſmall ſynovial gland near the glenoid cavity. The cartilage of the lower jaw is of an oval figure, interpoſed between the maxillary condyle and the baſe of the ſkull; its two ſurfaces are adapted to thoſe parts of the bones which come in contact with it. It is concave on the front, and convex on the back part of its upper ſurface, to correſpond to the articular eminence and glenoid cavity. Below it is concave, as it is applied only to the convexity of the condyle. Its two ſurfaces are cloſely covered by the correſponding portions of ſynovial membrane; the circumference is free between the reflexions of theſe membranes, except externally, where the outer ligament has a connection, and towards the front, where a few fibres of the external pterygoid muſcle are attached. It is thicker in the circumference than towards the centre, and may nearly equal the thickneſs of half a crown in the former ſituation; it is alſo thicker behind at the glenoid cavity than towards the front, where it is interpoſed between the convexities of the articular eminence and condyle. It is ſometimes penetrated by a hole in the middle, and then the two ſynovial membranes communicate with each other. It poſſeſſes the ſame fibrous ſtructure as the other articular cartilages; the fibres, which are concentric, are moſt evident towards the circumference.

Motions of the Jaws.—The mechaniſm of the face may be conſidered under two points of view; 1ſt, as affecting the bones, which conſtitute the upper jaw; 2dly, that of the lower jaw. Reſiſtance and ſolidity ſeem to have been the objects attended to in framing the former; and facility of motion in the latter.

Mechaniſm of the upper Jaw.—Force is applied to the upper jaw in three directions; 1ſt, from below upwards, which is the moſt ordinary caſe, as it takes place in maſtication; 2dly, from before backwards; 3dly, from ſide to ſide. It is very ſeldom that any impulſe or ſhock is received from above downwards. By the elevation of the lower jaw-bone, motion is chiefly tranſmitted, and the ſtrongeſt impulſe communicated to the dental margin or the upper. Hence the points of reſiſtance, or the ſupports of the latter, correſpond to this ſituation. The palatine arch, ſeparating the mouth and noſe, and placed behind and within the above-named margin, receiving little or no impulſe towards its middle, is furniſhed with a very ſlender ſupport in that ſituation. The naſal ſeptum indeed ſeems rather deſigned to divide the cavities, from which its name is derived, than to concur in the latter object, to which its ſtrength is manifeſtly inadequate. Moreover, as it is connected above to the thin cribriform plate, any ſtrong impulſe communicated in that direction might produce an injurious effect on the brain. We muſt turn our attention, therefore, chiefly to the dental margin of the upper jaw, in examining the reſiſtance which is experienced by the lower maxillary bone. And in this ſituation its ſupports are derived; in front, from the naſal proceſſes of the upper jaw-bones; and behind, from the malar bones, which, as well as the proceſſes juſt mentioned, are again ſuſtained by the os frontis. Hence the upper jaw will reſiſt the moſt powerfully in theſe two directions; and two intervals may be noticed between theſe points, in which no ſupport is afforded; *viz.* the opening of the noſe, and the orbits. The ſituation of the teeth is accommodated to this circumſtance. The inciſors, which are formed for the purpoſe of cutting ſoft kinds of food, are placed under the ſpace left at the entrance of the noſe. The cuſpidati, adapted by their ſize and ſtrength for tearing tough and hard ſubſtances, are ſupported by the naſal apophyſes; while the molar teeth, which bruiſe and finally comminute the food, are placed in the moſt reſiſting portion of the alveoli, *viz.* that which is ſupported by the cheek-bone. The bicuſpides, although found under the orbits, are ſufficiently ſupported by the union of the naſal apophyſes with the cheek-bones. The motion then communicated to the dental margin of the upper jaw is tranſmitted to the frontal bone, at its internal and external orbitar proceſſes. The ethmoid may likewiſe tranſmit a ſmall part of the impulſe, ſince it alſo is placed between the frontal and upper jaw-bones. The os malæ, which is impelled in this way upwards, is furniſhed with a point of reſiſtance behind, in the zygomatic portion of the temporal bone; and in that circumſtance conſiſts the advantage of the mode in which the latter overlaps the former. The preceding conſiderations render it very evident that all the impulſe, tranſmitted from the lower to the upper jaw, is ultimately communicated to the cranium, and there loſt. Hence it has been inferred, that if, in caſes of fracture, a reſiſting body be held between the teeth, and thrown into vibration; or if a hard body, as a nut, be cracked between the teeth; that the impulſe thus produced would occaſion motion, and conſequently pain in the place of the injury: and the older writers have even inſiſted on theſe ſigns as affording indications under doubtful circumſtances. They appear to us more like the offſpring of the imagination, than the reſult of obſervation and experience; yet we may often feel a kind of ſhock in the ſkull, when we exert the powers of maſtication very ſtrongly. Let us make one more remark on the latter ſubject; that the upper inciſor teeth ſlip over the lower ones, like the blades of ſciſſars; and that their flattened form and their edges favour this kind of motion, by which the interpoſed ſubſtances are cut in pieces. The cuſpidati overlap a little; but the grinders, which bruiſe the ſolid parts of the food, meet together in the ſame vertical line.

Impulſe can be produced in the ſecond direction, only by external objects; as in the caſe of a blow or fall on the face. The pterygoid proceſſes and the zygomatic arches are the reſiſting points, which ſuſtain the effort in thoſe caſes; and it is tranſmitted from theſe to the cranium. Perſons have ſuppoſed that a ſhock, affecting the front of the noſe, might be tranſmitted to the brain through the ſeptum narium. But that part is too weak for ſuch an effort, which, in point of fact, does not ſeem ever to occur.

The propagation of a lateral ſhock cannot be eaſily eſtimated, ſince there is no ſupport oppoſite to the part ſtricken. But it muſt no doubt be loſt in the ſide of the head.

The upper jaw will be found to move a little when the

mouth is opened; but the motion is common to the whole of the cranium with the jaw. The back of the head deſcends, while the front is ſlightly elevated; and the motion takes place between the occipital condyles and the atlas. The quantity of this movement is very ſmall, ſo that phyſiologiſts in general have overlooked it altogether, and have agreed almoſt univerſally in ſtating that the mouth is opened by the depreſſion of the lower jaw only. Haller and others have indeed been aware that the upper jaw could be moved in the manner juſt mentioned (Elementa Phyſiol. tom. vi. p. 10.); but they do not ſeem to know that ſuch a motion takes place in ordinary caſes. For the author laſt quoted expreſſes himſelf thus: "motum, quo os aperitur, *maxillâ inferiori non motâ*, ſed capite retrorſum ducto, per biventrem." Any individual may ſatisfy himſelf, that his upper jaw does aſcend, when the mouth is opened, if he will ſtand oppoſite to a looking-glaſs, holding the point of a knife juſt againſt the lower edge of the upper teeth, and then open his mouth.

Mechaniſm of the lower Jaw.—This may be depreſſed, elevated, moved backwards, forwards, and to either ſide. In the depreſſion, which is the principal means of opening the mouth, the condyle firſt turns a little on its own axis in the glenoid cavity, ſo that the upper part becomes rather anterior; the angles of the bone move backwards, and the coronoid proceſſes deſcend. When the depreſſion is ſlight, no further effect is produced; but if a more conſiderable opening of the mouth be needed, the condyle is carried ſuddenly forwards under the articular eminence of the temporal bone. This motion can be felt by placing the finger on the outer end of the condyle in the living ſubject; and it can be demonſtrated by moving the jaw, with the articulation diſſected, in the dead body. The cartilage is carried forwards with the condyle; the rotation of which going on at the ſame time, its poſterior portion is brought into contact with the articular eminence. The angle is carried farther and farther backwards, ſo that it moves juſt in an oppoſite direction to the condyle; the external ligament is rather tenſe, as well as the poſterior part of the upper ſynovial membrane; and the ſtylo-maxillary ligament is relaxed. If the depreſſion be carried to a very great extent, and be combined at the ſame time with a motion forwards, the condyle may become diſplaced, by ſlipping in front of the articular eminence.

The elevation of the jaw is effected by a motion of the bone in an inverſe direction to that which has been juſt deſcribed. The condyle placed under the articular eminence performs a rotatory movement, by which that part, which was before turned forwards, is directed upwards; and then the whole eminence returns into the glenoid cavity. When arrived in that part, it ſtill continues to turn upon itſelf, until the motion is arreſted by the lower teeth meeting the upper ones. If the depreſſion has been inconſiderable, the elevation is effected by that part only of the motion, which takes place in the glenoid cavity. The meeting of the teeth prevents the lower jaw from being ever elevated ſufficiently to produce a luxation backwards; which indeed is ſtill further prevented by the meatus auditorius and proceſſus vaginalis. In this motion the external ligament is relaxed; the ſtylo-maxillary becomes rather tenſe; and the poſterior part of the upper ſynovial membrane, which is naturally very looſe, becomes folded on itſelf in the cellular ſpace behind the fiſſura Glaſeri.

The jaw is moved forwards without any thing like that revolution, which we have deſcribed in the depreſſion. The whole bone is moved horizontally; and all the ligaments become equally tenſe. The ſuperior ſynovial membrane is ſtretched at its back part; while the inferior remains in its natural ſtate, ſince it accompanies the condyle in its motion forwards. For the pterygoideus externus, by which that motion is performed, attaching itſelf to both parts, carries them forwards together. This common inſertion is eſſential for the purpoſe of preſerving the condyle and cartilage in their proper relative poſitions. If the motion forwards were continued to a great extent, the coronoid proceſs would ſtrike againſt the anterior part of the temporal foſſa, and prevent any luxation; for which it is neceſſary that that apophyſis ſhould be depreſſed below the zygoma. The motion of the jaw forwards requires a ſlight previous depreſſion of the condyle, in order to bring its convexity to a level with the articular eminence, under which it is to be carried. But as the cartilage fills up much of the glenoid cavity, this depreſſion is very ſlight.

In the motion backwards, the whole jaw moves horizontally through the ſame ſpace in which it had paſſed forwards; and by a movement preciſely the inverſe of that which we have juſt deſcribed.

The lateral motion of the jaw is not of an horizontal nature. Indeed, if one condyle could be moved horizontally outwards, the other muſt be carried proportionally inwards; but the ſpine of the ſphenoid bone and the proceſſus vaginalis are the obſtacles to ſuch a motion; ſo that a luxation inwards or outwards is manifeſtly impoſſible. If the chin move towards the right, the following is the condition in which the lower jaw-bone is placed. The left condyle remains in the glenoid cavity, and is even more deeply fixed in that depreſſion, ſo as to form a pivot, on which the reſt of the bone turns. The other condyle, which is the part moſt remote from the centre of motion, exhibits that motion the moſt clearly. It quits the glenoid cavity, moves forwards under the articular eminence, and may even be luxated ſeparately, if the effort be very conſiderable. The ſtate of the left joint is then nearly the ſame as in the depreſſed condition of the jaw. The reader will of courſe underſtand that the chin is carried towards the left by a ſpecies of movement the inverſe of that now deſcribed.

Muſcles moving the lower Jaw.—The temporal muſcle, (temporalis, crotaphites, temporo-maxillien,) which is ſmaller in ſize in the human ſubject than in any of the mammalia, ariſes from an extenſive ſurface at the ſide of the cranium. Its origin commences by thin fleſhy fibres from the ſemicircular bony ridge, which, beginning juſt behind the orbit, paſſes backwards in an arched courſe over the middle of the parietal bone, and then turns forwards and downwards, ſo as to become continuous with the bony ridge which ſeparates the ſquamous and maſtoid portions of the temporal bone. (For a particular deſcription of this ridge, and of the ſpace included within it, ſee CRANIUM.) A ſtrong and denſe aponeuroſis ariſes from the whole extent of the temporal ridge, and, covering the muſcle, is implanted firmly in the ſuperior edge of the zygoma, and in the outer edge of the orbit. By means of this, a complete cavity is prepared for holding the muſcle; having its inner ſurface formed of the cranium, and the outer ſurface of this temporal faſcia; and opening below by the ſpace left between the zygoma and the ſurface of the ſkull. The muſcle ariſes then in a fleſhy form; 1ſt, from the whole bony ſurface included within the temporal ridge, and conſtituting the temporal foſſa (conſiſting of a greater or ſmaller portion of the four following bones, *viz.* os frontis, temporis, ſphenoides, and malæ); 2dly, from the inner ſurface of the zygoma; and 3dly, from the whole inner ſurface of the temporal faſcia. From theſe parts two layers of fleſhy fibres are produced, an internal and external; and theſe are implanted in a middle

radiated tendon, which is lodged for the greateſt part in the body of the muſcle, but comes out below to be attached to the coronoid proceſs of the lower jaw-bone. It deſcends between the zygoma and the ſide of the ſkull, and is implanted into the apex, the outer and inner margin, and the anterior edge of the coronoid proceſs.

The muſcle is thin above, and grows gradually thicker downwards; it is nearly flat on its two ſurfaces. The fibres have a radiated arrangement, as they paſs from an extenſive ſurface of origin to a ſingle point of inſertion. The anterior fibres paſs rather backwards; the next to theſe deſcend in a ſtraight courſe; and a very conſiderable portion comes obliquely forwards, filling up the ſpace left between the zygoma and the ſquamous portion of the temporal bone, and playing over the root of the zygomatic proceſs.

The temporal muſcle and its faſcia are covered by the aponeuroſis of the fronto-occipitalis; by the anterior and ſuperior muſcles of the ear; by the ſuperficial temporal veſſels and nerves; the zygomatic arch and the maſſeter muſcle.

It elevates the lower jaw, particularly when acting in conjunction with the maſſeter. If the bone has been carried forwards, it is again reſtored to its place, chiefly by means of the poſterior fibres. The anterior portion, which goes obliquely backwards, may concur with the pterygoideus externus in carrying the jaw forwards.

The *maſſeter* (jugo-maxillien) is a ſtrong and thick muſcle, compoſed of an intermixture of tendinous and muſcular fibres, quadrilateral but rather elongated in its figure, and covering the ramus of the lower jaw. It ariſes, 1ſt, from two thirds of the anterior and outer part of the lower edge of the zygoma, by a very ſtrong ſheet of tendon, which, covering a conſiderable part of the muſcle, detaches ſeveral plates from its inner ſurface into the ſubſtance of the part; 2dly, from the poſterior part of the ſame edge by a mixture of tendon and muſcle; 3dly, from the inner ſurface of the zygoma by ſhort tendinous fibres. The firſt portion conſtitutes the chief bulk of the muſcle, and, paſſing obliquely downwards and backwards, is implanted into the angle and neighbouring portion of the ramus of the lower jaw. The fibres of the ſecond claſs, deſcending vertically, are mixed with the former at their inſertion. The laſt diviſion paſſes obliquely forwards, and are inſerted high up in the ramus of the jaw, and near the coronoid proceſs.

This muſcle is covered externally by the platyſma myoides, the parotid gland and its excretory duct, the facial nerve, tranſverſalis faciei artery, zygomaticus and orbicularis palpebrarum muſcles. It covers the ramus of the lower jaw, which is rendered irregular on its ſurface by the attachment of the fibres, and a part of the tendon of the temporal muſcle. Its front edge is ſeparated from the buccinator by adipous ſubſtance.

It elevates the lower jaw, and is particularly employed on thoſe occaſions in which a conſiderable force is exerted; as in maſticating hard ſubſtances, whence its name ſeems to have been derived. In thoſe elevations of the part, which do not require ſo great an exertion, as in ſpeaking, the temporal muſcle is made uſe of. The outer and larger part may contribute ſlightly to move the jaw forwards, while the fibres which ſlope forwards may aſſiſt in reſtoring it. Is this muſcle, or the temporal, or the pterygoideus internus, exerted in depreſſing the head, ſuppoſing the lower jaw to be carried downwards, and to be held in that ſituation? This and the other elevators of the lower jaw are particularly affected by the ſpaſmodic trembling, produced by the action of cold on the ſkin; and are peculiarly ſubject to the attacks of tetanus. Paralyſis, on the contrary, is ſlow in affecting them; and they will be found often to act equally well on both ſides, when the whole face is diſtorted from hemiplegia.

Pterygoideus internus (ſpheno-maxillien) is placed on the inſide of the ramus of the jaw, oppoſite to the maſſeter, to which in figure and ſtructure it has a conſiderable analogy, although it is rather ſmaller in ſize. The aſcending part of the lower jaw-bone is indeed included between the fibres of this muſcle and the maſſeter; although the latter embraces it more cloſely on the outſide, than the pterygoid does internally. Its diſtinguiſhing epithet of *internus* denotes merely that it ariſes from a more internal part of the pterygoid proceſs than the *externus*, and not that it is ſituated more deeply. It ariſes from the whole of the pterygoid foſſa; conſequently from the inner ſurface of the external, and from the outer ſurface of the internal plate, and from the pterygoid proceſs of the os palati. Its fibres, conſiſting, like thoſe of the maſſeter, of an intimate mixture of tendon and muſcle, deſcend and paſs at the ſame time outwards, and ſlightly backwards, to be attached to the angle, and to the inner ſurface of the ramus of the inferior maxillary bone; and are ſometimes mixed, under the edge of the bone, with thoſe of the maſſeter.

The inner ſurface of this muſcle correſponds to the circumflexus palati, to the ſpace ſeparating that muſcle from the conſtrictor pharyngis ſuperior, and lodging ſeveral nerves, veſſels, &c., and to the ſub-maxillary gland. Externally it is ſeparated from the jaw above by the dental and lingual nerves, and by the dental veſſels.

It concurs with the two former muſcles in elevating the lower jaw; and it aſſiſts in moving the bone towards the right or left, when it acts ſeparately.

The three pairs of muſcles now deſcribed unite in producing the elevation of the lower jaw; which is termed biting, when any ſubſtance is intercepted between the upper and lower teeth. Their ſtrength is very conſiderable, as the nature of their office obviouſly requires, and its extent is evinced by various inſtances of exertion. Veſalius mentions a man who could throw behind him an iron bar of twenty-five pounds weight held in the mouth, ſo as to fix it in a beam at the diſtance of thirty-nine feet; and inſtances are not uncommon of perſons balancing on the chin a plank or ladder ſo heavy that they can barely lift it. Haller has collected ſeveral examples, as the elevation of a maſt, and placing it on the ſhoulder; of a table ſix feet broad, with a weight of 60 pounds, hanging to the oppoſite ſide; and of 300 pounds weight, &c. We muſt recollect alſo that theſe exertions require much greater force than the weights would ſeem to indicate; ſince the muſcles are all inſerted near the centre of motion, and the force acts at a conſiderable diſtance from the lever; hence it has been calculated that the whole power would be equal to 1000 or 1800 pounds. Man, therefore, is admirably provided with inſtruments for triturating the food, more powerful indeed than ſeems neceſſary for the reduction of aliments, prepared by the various arts of cookery. Yet theſe are trivial compared to the ſtrength of the correſponding muſcles in predacious animals, where the jaws conſtitute moſt terrible inſtruments of attack and defence, and are able to comminute the bones, which are ſwallowed with the reſt of the prey.

Pterygoideus externus (ſpheni-maxillien) is a thick muſcle, placed obliquely between the pterygoid proceſs and the condyle of the lower jaw. It ariſes from the outer ſurface of the external pterygoid plate, from the neighbouring part of the os palati, and from the ſphenoid bone towards the temporal foſſa. Its fibres paſs obliquely backwards and outwards, and are inſerted into the foſſicula of the front of the condyle,

dyle, and into the articular cartilage of the jaw. It is covered externally by the temporal muſcle, and internal maxillary artery; internally by the pterygoideus internus, and the inferior maxillary nerve, and above by the zygomatic foſſa. The right and left muſcles acting in conjunction will carry the two condyles directly forwards under the articular eminence. If the right ſhould act ſeparately, it will carry forwards the condyle of its own ſide, and thereby move the chin towards the oppoſite ſide, and *vice verſâ*. It always acts upon the cartilage, as well as upon the condyle.

Digaſtricus or *biventer maxillæ inferioris* (maſto-maxillien) is placed at the ſide of the upper part of the neck; poſſeſſes an elongated form; and conſiſts, as its names imply, of two portions of muſcle joined by a middle tendon. It ariſes by a mixture of tendinous and fleſhy fibres from the groove within the maſtoid proceſs, and deſcends obliquely forwards and inwards. This, which is called the poſterior belly of the muſcle, grows at firſt gradually thicker from its origin; then again decreaſes, and is contracted into a roundiſh tendinous chord, which paſſes through the fibres of the ſtylo-hyoideus, or behind that muſcle, and running about half an inch above the os hyoides, is connected to that bone by a thin aponeurotic expanſion. Afterwards it is reflected upwards and forwards at an obtuſe angle, and ſpreads out into the anterior fleſhy belly, which is about an inch in length, advances to the lower edge of the front of the jaw, approximating to the oppoſite muſcle, and is inſerted into the ſuperficial foſſa at the ſide of the ſymphyſis.

The trachelo-maſtoideus, ſplenius, and ſterno-cleido-maſtoideus muſcles cover the poſterior fleſhy portion of the digaſtric, which again in its turn covers the muſcles of the ſtyloid proceſs, the internal jugular vein, and internal carotid artery; ſome branches of the external carotid artery, and the nerves of the ninth pair. The anterior part is placed between the mylohyoideus and latiſſimus colli. The ſubmaxillary gland, placed between the two diviſions of the muſcle, is bounded below by the middle tendon.

The contraction of this muſcle opens the mouth by drawing the front of the lower jaw towards the maſtoid proceſs; and the ſwelling both of its anterior and poſterior portions can be plainly perceived by the finger, when we open the mouth. The office of the digaſtricus does not ſeem to be much connected with the motions of the os hyoides, ſince its tendon paſſes above that bone, to which it is only connected by a ſlender aponeuroſis, and conſequently the curve deſcribed by the courſe of the muſcle is ſlight; now it is only in proportion to the degree of that curvature that the digaſtricus taken altogether can have the power of elevating the os hyoides. The anterior portion draws the os hyoides to the jaw, or *vice verſâ*, if the fixed points be changed; the poſterior carries the former bone backwards and upwards. Both will elevate the os hyoides when it is depreſſed. If the lower jaw be rendered a fixed point, the digaſtric may depreſs the back of the head upon the ſpine, and thereby open the mouth by elevating the upper jaw. That this part does more, when the lower maxillary bone is prevented from deſcending, is very obvious; and Soemmerring ſtates that the circumſtance may be obſerved particularly in infants when ſucking.—(De Corp. Hum. Fabr. t. 3. p. 105.)

Latiſſimus colli (platiſma myoides, thoraco-facien).—This muſcle conſiſts of a very thin layer of muſcular fibres, ſituated under the ſkin of the neck, the whole ſide of which is covered by it, and extending over a conſiderable part both of the face and cheſt. The weakneſs of its fibres is compenſated by its great breadth. Its ſituation is under the ſkin and adipous membrane. It ariſes by ſcattered and ſeparate portions among the cellular membranes at the upper part of the cheſt, at one or two inches below the clavicle. Theſe origins cover a part of the pectoralis major, deltoid and trapezius muſcles. Its ſeparate origins uniting into a broad and thin continuous ſtratum, extend upwards, forwards, and inwards, covering the muſcles, veſſels, and nerves, of the neck. The two muſcles decuſſate each other at the upper part of their inner edge, where they are attached to the lower jaw: they are not quite in contact below. The poſterior edge repreſents an oblique line deſcending from the angle of the jaw towards the middle of the ſhoulder. When the fibres have arrived at the baſis of the lower jaw, they terminate in two ways. The inner portion is fixed to the ſymphyſis of the bone, and to its lower edge, juſt under the origin of the depreſſor anguli oris; a few fibres however paſs over the bone to the integuments of the chin. The outer diviſion aſcends over the jaw, and turns, when it has arrived on the face, by a gentle ſweep, inwards and forwards, to the corner of the mouth. Here its fibres partly terminate in the cellular membrane of the face, and are partly connected with the orbicularis at the corner of the mouth, and with the depreſſor anguli oris throughout its whole external edge. The external ſurface of this muſcle is everywhere connected to the ſkin by an adipous membrane, not much charged with fat. On the oppoſite aſpect, it is in contact, on the cheſt, with the pectoralis major, deltoid, and clavicle. On the neck, it covers the greateſt part of the ſterno-cleido-maſtoideus, a part of the omo-hyoideus, the ſterno-hyoideus, digaſtricus, and mylo-hyoideus; the external jugular vein; the carotid and ſuperior thyroideal arteries; the ſub-maxillary, and a part of the parotid glands. In the face it lies upon the maſſeter, buccinator, and depreſſor anguli oris muſcles, and the external maxillary artery and facial vein, &c.

It draws down the ſkin of the lateral and lower part of the face, and particularly aſſiſts in depreſſing the lower lip, and corner of the mouth. It muſt conſequently be concerned in expreſſing the ſorrowful and indignant paſſions. It alſo acts very principally in depreſſing the lower jaw. In all its contractions the integuments muſt be thrown more or leſs into tranſverſe wrinkles, and this effect reſembles that produced by the panniculus carnoſus of animals; but we cannot regard this corrugation as the primary uſe of the muſcle.

Other muſcles aſſiſt in depreſſing the lower jaw, as thoſe which paſs from that bone to the os hyoides, alſo the depreſſors of the os hyoides, all which will be deſcribed in a ſubſequent part of the preſent article. The powers, which we have juſt conſidered as being concerned in opening the mouth, by carrying the lower jaw towards the cheſt, appear exceedingly weak when contraſted with their antagoniſts the maſſeters, temporal and pterygoid muſcles. The diſproportion will be leſſened by the circumſtance of the depreſſors being all inſerted at a diſtance from the centre of motion, and conſequently acting with a very conſiderable mechanical advantage. We muſt conſider alſo that the office of the laſt-mentioned muſcles requires no great exertion; that when the elevators are relaxed, the weight of the jaw itſelf aſſiſts in the depreſſion; and conſequently that the depreſſors of the jaw hold the ſame relation to the elevators, as the extenſors do to the flexors in the trunk and limbs; where all the great efforts are made in the direction of flexion, and extenſor muſcles are required only for the purpoſe of reſtoring the parts.

The cavity of the mouth is the ſpace included between the lips and cheeks on the front and ſides; the palatine arch and the ſoft palate above and behind; the tongue and membrane of the mouth below. It opens to the front by a tranſverſe aperture placed between the two lips, and differing in ſize and figure, according to the motions of thoſe parts; behind it

communicates with the bag of the pharynx. The general direction of the cavity, in the erect poſition of the body, is horizontal; with the former opening placed directly forwards, and the latter backwards.

The circumference of the palate is terminated on its anterior and lateral aſpects by the alveolar portion of the upper jaw, containing the upper ſeries of teeth. The correſponding part of the inferior maxillary bone, with the lower teeth, projects into the mouth below. When the cavity is ſhut, the two rows of teeth meet together, and divide it into two parts having no communication with each other; *viz.* an outer or front diviſion, ſituated between the lips and cheeks, on one ſide, and the outer ſurface of the teeth and their ſockets on the other; and an inner or back part, including the ſpace left within the arches deſcribed by the teeth. In the open ſtate of the mouth theſe two diviſions communicate by the wide aperture left between the two rows of the teeth.

The extent of the cavity of the mouth differs in its different directions. When it is ſhut, the ſuperior ſurface of the tongue is in contact with the palate, and the lips and cheeks are applied againſt the teeth; ſo that there is no cavity or empty ſpace at all in this condition of the organs. When the proceſs of maſtication is going on, the tongue and jaw deſcend, and the lips and cheeks are diſtended with the food; thus the cavity is increaſed in all its dimenſions. The perpendicular diameter, which in the quieſcent ſtate of parts was reduced to nothing, becomes more and more conſiderable in proportion to the depreſſion of the lower jaw. The meaſure from ſide to ſide, in the firſt-mentioned ſtate, is the diſtance between the outer edges of the teeth on each ſide; and that from before backwards is nearly the ſame as the laſt. Both theſe diameters will be affected conſiderably by the motions of the lips and cheeks, and will be greater or ſmaller, according to the diſtenſion of thoſe organs.

The cavity of the mouth is lined by a ſoft and vaſcular membrane, continuous at the front aperture with the common integuments of the face; extended behind into the pharynx; and differently organized in different parts of its courſe. From the looſe and tumid edges of the two lips, it is produced over their inner ſurface, and that of the cheeks; beſtowing a ſoft lining on both of theſe parts. It then covers the outer alveolar plate of the two jaws; and, in its reflection from the lips, it produces, both above and below, a ſmall fold, which confines theſe parts more cloſely juſt at the middle and front part of each maxillary bone. Theſe duplicatures are named the fræna of the lips. Aſcending over the outer alveolar plate, it approaches the necks of the teeth, aſſumes a greater firmneſs of texture, and forms the gums. On the alveolar edges of the maxillary bones, and, conſequently, in the middle of that part which forms the gum, the membrane is perforated by a number of holes equal to that of the teeth; and it adheres cloſely to the necks of the teeth at the margins of theſe perforations, where it is alſo connected with the periоſteum that lines the alveoli. It is then continued over the internal alveolar lamina of both jaws; affords a covering above to the bony palate; and is prolonged over the under ſurface of the ſoft palate, at the poſterior or looſe edge of which it becomes continuous with the pituitary membrane of the noſe. From the cheek it goes over the ramus of the jaw, and is continued with the membranous fold that paſſes from the ſoft palate to the tongue. After covering the inner alveolar plate of the lower jaw, it paſſes to the under ſurface and ſides, and then to the upper part of the tongue. Oppoſite to the ſymphyſis of the bone, and juſt over the attachment of the genioglоſſi, it makes a fold, called the frænum, which limits the motions of the tongue. In other ſituations the membrane is produced looſely from the bone to the tongue; and it covers on each ſide towards the front a ſmall oblong eminence, formed by the projection of the ſublingual ſalivary gland. From the back of the tongue the membrane is extended over the epiglottis, and forms three folds, connecting that organ to the ſurrounding parts.

The moveable and nearly hemiſpherical covering, conſiſting of common integuments on the outſide, of a ſoft vaſcular membrane internally, and having a conſiderable number of muſcles, together with more or leſs fat, and numerous glandular bodies interpoſed between theſe;—extended from the cheek-bone, upper jaw, and front of the noſe, ſo as to cover the two rows of the teeth, and attached below to the whole length of the alveolar portion of the lower jaw; and poſſeſſing a middle tranſverſe fiſſure, parallel to the teeth, and correſponding to the interval of the two rows, but much ſhorter than that interval;—conſtitutes the *lips* and *cheeks*.

The *lips* are the two moveable portions of the above-deſcribed production, placed before the front teeth, bounding the mouth at its anterior part, and forming, by their red and ſoftly-ſwelling edges, the margins of the opening of the mouth. The *upper lip* includes the part placed between that opening and the noſe: the *lower* is the portion between the ſame orifice and the lower jaw. Theſe organs are very important, from the influence which they exert on the general expreſſion of the countenance, not to mention their ſhare in articulation, maſtication, &c. They are united at the two corners of the mouth by acute angles, named their commiſſures. Theſe are entirely muſcular; ſo that they admit of conſiderable extenſion and retraction. Their looſe edge, which is their thickeſt part, and is marked by ſeveral lines croſſing between the two margins, is the point of continuity between the mucous membrane of the mouth, and the common integuments.

The external ſtratum of the lips conſiſts of ſkin remarkable for its thinneſs, as well as for the hairs which grow in it, and form the beard, one of the great characteriſtic differences between the male and female ſubject. This is ſucceeded by a layer of muſcular fibres, united to the former by a cloſe cellular texture, in which there is very little fat. This layer is compoſed principally of the orbicularis oris; to which are added the elevators of the upper lip, and of the corner of the mouth above, the buccinator zygomaticus and depreſſor anguli oris at the commiſſure, and the depreſſors of the lower lip below. The muſcular layer is followed by a conſiderable number of large, rounded, mucous glands (*glandulæ labiales*), arranged in an uniform ſtratum, covered towards the mouth by the mucus membrane, in which they often cauſe conſpicuous prominences, and poſſeſſing excretory ducts, which perforate that membrane. The mucous lining of the lip reſembles that of the mouth in general: it is very vaſcular, and becomes of a general and deep red from minute injections; its ſurface is moiſtened by the mucous ſecretion of the glandulæ labiales. The red ſwelling part, which forms the very opening of the mouth, is diſtinguiſhed from the common ſkin, externally, by a clearly defined line, and from the mucous membrane on the inſide. It is this part which forms, by its clear tranſparent redneſs, ſo beautiful a contraſt with the pearly whiteneſs of the teeth. It poſſeſſes cuticles, which often ſeparate in dry and ragged portions, particularly in cold weather. The cutis at this part is furniſhed with numerous villi, indicating a high degree of organization; and the pleaſurable phyſical ſenſation, experienced in kiſſing, correſponds with this ſtructure. The entire want of fat, or the very ſmall quantity which does exiſt in the lips, occaſions theſe parts to retain almoſt conſtantly the ſame thickneſs: which is not more favourable

to

to their functions than if they had changed according to the embonpoint, or thinneſs of the body in general.

The external opening of the mouth is the ſpace left between the two lips. Its direction in the quieſcent ſtate is tranſverſe; and it does not then exiſt as an opening, ſince the two lips are in contact. The free power of motion, which the ſides of the aperture poſſeſs in every direction, renders it ſuſceptible of very numerous varieties, both of ſize and figure. In the moſt contracted ſtate, it forms a ſmall tranſverſe groove with corrugated edges. It may be extended laterally by the ſeparation of both corners, until thoſe parts are brought oppoſite to the laſt bicuſpis, or firſt molar tooth. In the perpendicular direction, it is affected chiefly by the depreſſion of the lower jaw; but it may alſo be changed by the motions of the lips merely, which can be ſeparated to a conſiderable diſtance, their edges being at the ſame time turned out, and a larger ſurface of the red part being expoſed.

The *cheeks*, forming the lateral boundaries of the mouth, are parts of ſimilar organization to the lips, with which, indeed, they are entirely continuous, ſo that there is no natural diſtinction between them. Externally, their extent is not defined by any preciſe limits; but thoſe uſually aſſigned are the cheek-bone above, the baſe of the lower jaw below, the commiſſure of the lips in front, and the projection of the maſſeter behind. Towards the mouth on the contrary, they are bounded preciſely, both above and below, by the reflexions of the mucous membrane from their ſurface to the jaw-bones; behind by the folds of membrane deſcending from the velum palati, and in front by the commiſſure of the lips. Their thickneſs depends on the quantity of fat which they contain, which is ſubject to conſiderable variety. The external ſtratum of the cheek conſiſts of a thin and delicately organized ſkin, from which there are but few hairs growing, particularly towards the middle. In this part it is particularly diſtinguiſhed by its capillary ſyſtem, through which a large quantity of blood is conſtantly circulating in young and healthy perſons. This being liable to ſudden and accidental changes, either of increaſe or diminution, becomes an involuntary index of the affections of the mind; whether, as in the pleaſurable motions, and likewiſe in anger, indignation, its momentary diſtenſion gives riſe to that vivid redneſs of the cheek, which extends, in a diminiſhed degree, to other parts of the face; or, as in the depreſſing and ſorrowful paſſions, the ſame parts become overſpread with a more or leſs ſudden paleneſs. The capillary ſyſtem of the cheeks is alſo variouſly affected in diſeaſe, where it is ſometimes emptied of its blood, and in other caſes diſtended with an unuſual quantity. It alſo admits coloured injections very readily in the dead ſubject. Under the integuments of the cheek, we have the zygomaticus muſcle, covering a conſiderable quantity of ſoft fat, contained in a looſe cellular texture. This facilitates the motions of the buccinator and neighbouring muſcles, and augments conſiderably the tranſverſe diameter of the face. It is abſorbed very rapidly in various diſeaſes, and ſoon replaced in a ſtate of convaleſcence; ſo that the figure of the cheeks becomes an index of the general health. Under this fat the whole ſurface of the cheek is covered by the buccinator muſcle; which is lined *internally by the mucous membrane of the mouth*, ſeveral round mucous glands (*glandulæ buccales*) being interpoſed between it and the muſcle.

Muſcles of the Lips and Cheeks.

Naſalis labii ſuperioris.—This, which is deſcribed by Albinus as a diſtinct muſcle, is undoubtedly a part of the orbicularis. It ariſes in a pointed form from the tip of the noſe, and from the ſeptum narium, and, growing thicker as it deſcends, turns outwards, and terminates in the orbicularis. It will approximate the corners of the mouth, and depreſs the apex and ſeptum of the noſe. It will alſo elevate and turn outwards the upper lip, ſo as to apply it againſt the openings of the noſtrils.

Levator labii ſuperioris et alæ naſi, (pyramidal and lateral dunez).—This is very commonly deſcribed as forming two ſeparate muſcles, a proper elevator of the upper lip, and a common elevator of it and the ala naſi: we do not conſider the diſtinction ſufficiently marked, and therefore deſcribe them together. It ariſes in a pointed manner, from the naſal proceſs of the upper jaw, where it is confuſed with the frontal muſcle; it deſcends along the ſide of the noſe from this origin, and has a ſecond very broad attachment, diviſible into two or more portions, to the ſuperior maxillary bone, along the front edge of the orbit, and above the infra-orbitar foramen. This ſecond portion of its fibres paſſes obliquely downwards and inwards to join the former; and on its outer edge it is ſometimes continued by irregular fibres to the zygomaticus. Its inſertions are, 1ſt, into the alæ naſi, where it is united with the compreſſor narium, and depreſſor alæ naſi; 2dly, into the upper lip, as far as the corner of the mouth, by an union of its fibres with thoſe of the orbicularis oris, and levator anguli.

It is covered on the noſe partly by the integuments, and by the orbicularis palpebrarum and facial vein; lower down by the two former parts. It covers the os naſi, the naſal proceſs of the ſuperior maxillary bone, the depreſſor alæ naſi, levator anguli oris, and infra-orbitar veſſels and nerves. It elevates the upper lip, and the alæ of the noſe; and as both theſe effects are produced by the ſame muſcle, it is difficult to raiſe the lip without, at the ſame time, moving the noſe. Its action cauſes a ſwelling of the integuments between the lip and the eye. As it is attached towards the front of the lip, it turns that part outwards and upwards: and, in conſequence of the oblique courſe of a great part of its fibres, it extends the lip horizontally at the ſame time that it produces the elevation. It acts in the ſmile of deriſion, and is exerted in all the angry and ſcornful affections of the mind.

Zygomaticus major, or diſtortor anguli oris.—This is a rather elongated and ſlender muſcle, produced in an oblique direction from the convexity of the os malæ to the corner of the mouth, and terminating by a continuation of its fibres with thoſe of the orbicularis and other muſcles of the lips. It is covered externally by the ſkin of the cheek, and it lies upon the os malæ, the facial vein, and the buccinator muſcle. It draws the corner of the mouth towards the temple, and thereby cauſes a ſwelling of the cheek. The right and left muſcles acting together enlarge the mouth horizontally, and draw the corners upwards, as in laughing. There is ſometimes, but not conſtantly, a *zygomaticus minor*, placed in front of the preceding muſcle, and conſiſting of a thin faſciculus of fibres, which have a ſimilar origin, direction, inſertion, and uſe, as the greater zygomaticus.

Levator anguli oris, or *labiorum communis* (le canin).—It has a thin and flat origin from the hollow of the upper jaw-bone, juſt under the infra-orbitar foramen. Its fibres paſs obliquely downwards and outwards to the corner of the mouth, where it mingles with thoſe of the orbicularis and depreſſor anguli. On its anterior ſurface lie the levator labii ſup. et alæ naſi, with the infra-orbitar veſſels and nerves. Behind it are placed the ſurface of the jaw-bone, the membrane of the cheek, and the buccinator. It elevates the corner of the mouth, and thereby reſtores the parts which have been depreſſed in the ſorrowful emotions.

Depreſſor

Depreſſor anguli oris (triangularis), is a muſcle of a flattened and triangular figure, extended from the ſide of the chin to the corner of the mouth. It has a broad origin from the anterior part of the baſis of the lower jaw, grows narrower as it aſcends, has its fibres ſlightly arched towards the chin, and terminates at the corner of the mouth by uniting with the zygomaticus, levator anguli, and orbicularis. Its outer edge is a point of inſertion to numerous fibres of the platyſma myoides. Covered by the ſkin externally, it lies upon the depreſſor labii inferioris, and buccinator. It depreſſes the corner of the mouth, and is a very important muſcle, in a phyſiognomical point of view, as it acts in all the ſorrowful emotions. Its effects can be well ſeen in crying.

Depreſſor labii inferioris proprius (quadratus.)—It ariſes from about one inch of the anterior and lateral part of the jaw, covered at its origin by the former muſcle. Its fibres paſs obliquely upwards and inwards, and mingle with thoſe of the oppoſite muſcle. It terminates by a broad inſertion into the lower lip, confounding its fibres with thoſe of the orbicularis. The preceding muſcle, the levator menti, and the latiſſimus colli are alſo connected with it; and there is much fat mixed with its fibres. The depreſſor anguli and ſkin (to which it is ſtrongly united) cover this muſcle externally; and it covers on the other ſide the levator menti, the mental veſſels and nerves, and the orbicularis. It draws the lower lip down to the chin.

Levator menti (elevator proprius lab. infer.; inciſif inferieur).—This ariſes from the lower jaw-bone, about the ſocket of the cuſpidatus, by firm fleſhy fibres, which deſcend inwards, and join thoſe of the oppoſite ſide, being ſtrongly united with thoſe of the depreſſor lab. infer. It terminates in the cellular ſubſtance and ſkin of the projecting part of the chin. It elevates and corrugates the chin; it reſtores the lower lip, when that has been depreſſed. By drawing up the chin, it will evert the lower lip, as we ſee occaſionally in ſcorn and deriſion.

The *buccinator* is the largeſt muſcle of the lips. It is thin, but very broad; flattened on its ſurfaces, nearly quadrilateral, occupying the ſpace between the two jaws, and ſpread immediately over the membrane of the cheek. It ariſes from the tubercle of the upper jaw, from the pterygoid proceſs, ſide of the pharynx, and ſpace between the laſt grinder, and coronoid proceſs of the lower jaw. Its fibres purſue a tranſverſe courſe to the lips, and are parallel to each other. They terminate under the elevator and depreſſor muſcles juſt deſcribed, by uniting their fibres with thoſe of the orbicularis oris. It is perforated by the duct of the parotid gland. The buccinator muſcle is ſeparated from the coronoid proceſs, and maſſeter, which lie over it behind, and from the zygomaticus major, facial artery and vein, and latiſſimus colli, which cover it towards the front, by a conſiderable quantity of fat. Its inner ſurface covers the mucous membrane of the mouth. It draws the whole of the mouth backwards, and thereby corrugates the cheek. It admits of mechanical diſtenſion by air or food contained in the mouth, and acts on thoſe in various ways. It expels the air in perſons who are blowing wind inſtruments; it puſhes the food under the teeth in maſtication, or towards the back of the tongue previouſly to deglutition.

Orbicularis oris (le labial; ſemiorbiculaire ſuperieur and inferieur).—This muſcle, which ſurrounds the opening of the mouth, conſiſts of concentric fibres forming an elongated oval, with its long axis placed horizontally. It is flattened on its anterior ſurface. The fibres compoſing it may be divided into the common and the proper. The firſt of theſe conſtitute the exterior portion of the muſcles, and conſiſt of the union and intermixture of the various muſcles belonging to the lips: *viz.* the levator labii ſuperioris et alæ naſi, zygomaticus minor, and naſalis labii ſuperioris above; the depreſſor labii inferioris and levator menti below; and the zygomaticus major, levator anguli oris, buccinator and depreſſor anguli oris at the commiſſure. Theſe are all ſo mingled together, that we cannot deſcribe any particular courſe of fibres in that portion of the orbicularis which is formed by their union. The proper fibres of the orbicularis are placed within the former, being continuous with them, and correſponding to the looſe edge of lips. This muſcle is cloſely covered by the ſkin externally, by the red part of the lips on its inner circumference, and by the glandulæ labiales and mucous membrane towards the mouth. The orbicularis oris is the antagoniſt of all the other muſcles that move the lips, and reſtores theſe parts, when they have been moved out of their natural ſituation in any direction. It brings them into contact with each other in an horizontal line, ſo as to cloſe the mouth. When it is neceſſary to contract the mouth beyond this degree, as in blowing ſeveral wind inſtruments, the orbicularis is employed, and cauſes a corrugated ſtate of the lips. It brings theſe parts in cloſe contact with any body round which they may be applied in the act of ſuction. The action of their exterior fibres tends to evert the edges of the lips, ſo as to bring the red part more completely into view.

There are ſometimes connected with the muſcles above deſcribed ſome irregular fibres, which do not exiſt conſtantly. There is frequently a portion of muſcles croſſing tranſverſely between the right and left platyſma, juſt at the chin; the *tranſverſus menti* of Santorini. Some fibres ariſing in the cellular ſubſtance over the maſſeter, or from the platyſma myoides, and paſſing to the corner of the mouth, have been deſcribed under the name of *riſorius*. Soemmerring has deſcribed by the epithet of *anomalus maxillæ ſuperioris*, ſome irregular fibres, ſituated under the levator of the upper lip, and inſerted by both extremities into the upper jaw-bone.

The palate, compoſing the upper ſurface of the mouth, is nearly of a parabolic figure, extending rather more in length than in breadth. Its poſition is nearly horizontal in the ordinary erect attitude; and as its bony ſtructure renders it completely motionleſs of itſelf, it offers a fixed point of reſiſtance to the tongue in the motions of articulation and deglutition. It conſiſts of a vaulted bony ſurface, covered by a thick and compact membrane. We muſt diſtinguiſh in the bone the alveolar portion, and the proper palatine arch. The former conſtitutes a parabolical projection, which limits the palate at its anterior and lateral aſpects, and contains on its inferior ſurface the openings of the alveoli. This belongs entirely to the ſuperior maxillary bones, and ſurmounts the upper row of teeth which borders the palate. The proper palatine arch is made up of the horizontal portions of the ſuperior maxillary and palatine bones.

The palate, when conſidered in its perfect ſtate, preſents a very conſiderable concavity towards the mouth. In the child, which has not yet cut its teeth, and where conſequently the alveolar proceſs is not yet formed; and in the old ſubject, where theſe organs, together with the bone in which they were implanted, have been loſt, this part of the mouth preſents a very different appearance from that which it has in the intervening periods. It exhibits a nearly level ſurface, inſtead of a conſiderable concavity. The lower jaw-bone undergoes a ſimilar change in advanced age; hence the cavity that holds the tongue becomes very conſiderably diminiſhed, and the motions of that organ in articulation and chewing are proportionally impaired.

The membrane of the palate preſents a very different ar-

rangement on the alveolar and palatine portions of the bone. In the former ſituation, it conſtitutes in the fœtus a thick, denſe, firm, and whitiſh layer, covering the alveoli and rudiments of the teeth, and forming a reſiſting ſurface capable of the efforts required in that ſpecies of maſtication which is then exerciſed. This is pierced by the teeth when they appear in the mouth; and its ſides, adhering round the neck of the tooth, conſtitute the gum. When the teeth and alveoli are loſt, the perforations of the gum are deſtroyed by the cloſing of their ſides, and a ſimilar hard white ſubſtance to that of the fœtus again occupies the alveolar edges of the jaws, and affords conſiderable aſſiſtance in old age in the act of maſtication.

The membrane covering the palate is thick, and cloſe in its texture. It is divided by a middle line into two halves, more perceptibly in the fœtus than in the adult. Its ſurface is irregular, and marked towards the front by tranſverſe lines: between it and the bone are ſeveral mucous glands, *(glandulæ palatinæ,)* with excretory ducts, opening conſpicuouſly on the ſurface, which become more numerous towards the velum palati, with the anterior ſurface of which the palatine membrane is continuous.

The poſterior boundary of the mouth is formed by a fleſhy and moveable curtain, extended from the back of the palatine arch into the pharynx, and called the *ſoft palate*, or *velum palati*. Thus it is placed above the opening, which leads from the mouth into the pharynx, and is ſeparated by that aperture from the baſe of the tongue. Its figure is nearly quadrangular; and it poſſeſſes two ſurfaces, of which one is anterior, and the other poſterior; and four margins, of which two are lateral, one ſuperior, and the other inferior. The anterior ſurface, which is turned towards the tongue, and faces downwards and forwards, is ſmooth and uniform, and gently concave, preſenting ſeveral ſmall openings of the mucous ducts; the poſterior, which is directed upwards and backwards, has a conſiderable elevation on each ſide, ariſing from the courſe of the levator palati muſcle, and a ſmaller one in the middle from the azygus uvulæ. The ſuperior margin is fixed to the back edge of the palatine bones, and this is the thickeſt part of the velum. The inferior border hangs looſely into the pharynx, and is divided into two parts by a conically ſhaped body, projecting exactly from the middle of the velum, and named the *uvula*. The broader part of this organ is rather flattened, and is placed upwards; the ſmaller portion is more cylindrical in its figure, and is directed downwards, terminating in an obtuſe extremity. It varies in length in different individuals, and in the ſame perſon, according to the ſtate of its elevator muſcle. It ſometimes hangs down ſo as to touch the tongue; and when it is thus permanently relaxed, it cauſes a very diſagreeable irritation. In its natural ſtate it points nearly to the foramen cœcum of the tongue, and is therefore conſiderably in front of the epiglottis. It is peculiar to the human ſubject, and to animals of the monkey kind; in other inſtances, the lower edge of the ſoft palate is nearly ſtraight. The preſence of the uvula cauſes the correſponding part in man to form a double arch.

The lateral edges of the ſoft palate are continued with the tongue and pharynx by two membranous and muſcular folds. Theſe are united at their origin, which takes place at the outer corner of the lower edge of the palate; but they ſeparate from each other as they deſcend. The anterior *(gloſſo-palatine)* terminates on the ſide of the baſe of the tongue; the poſterior *(pharyngo-palatine)* is loſt on the ſide of the pharynx. A triangular ſpace, formed by their ſeparation, contains the tonſil.

The contracted opening, by which the mouth communicates with the pharynx *(iſthmus faucium)* is chiefly formed by the parts now deſcribed. If we take a front view of it, as when we look into the throat of a living perſon, we find it bounded below by the root of the tongue; above by the lower edge of the ſoft palate, divided into two arches by the uvula; and at the ſides by the gloſſo-palatine folds of membrane continued from the palate to the tongue. Juſt behind theſe the convex ſurface of the tonſils is diſcernible. In the back view of the ſame aperture, from the bag of the pharynx, we ſee, as from the front, the tongue below, and the double arch of the palate with the uvula above. But the ſides are here formed by the pharyngo-palatine folds, produced from the velum in a perpendicular direction to the ſides of the pharynx. The convexity of the tonſil is conſpicuous alſo in this view.

The ſoft palate has two membranous ſurfaces, of which the anterior is continuous with that of the palate, and the poſterior with the pituitary membrane. Theſe are continued into each other at the looſe edge of the curtain. The palatine portion of the membrane covers a thick layer of granular bodies, which pour out a copious mucous ſecretion from numerous pores eaſily diſtinguiſhable by the naked eye. The uvula contains a conſiderable maſs of ſimilar glands. The muſcles of the palate contribute alſo to its ſubſtance. The azygus uvulæ occupies the centre, and the levator and circumflexus palati are expanded in the lateral portions of the velum. The folds produced from the palate to the tongue and pharynx contain alſo muſcular fibres.

The remarks which we have to make reſpecting the motions of the ſoft palate, and the effect which theſe produce on the iſthmus faucium, will be given in the deſcription of the pharynx.

Muſcles of the Palate. Levator palati mollis (ſalpingo-ſtaphylinus; periſtaphylinus internus).—This muſcle conſiſts of a conſiderable collection of fibres; it is rounded above, and flattened below, and ſituated at the ſide of the poſterior opening of the noſe. Ariſing from the under ſurface of the petrous portion of the temporal bone, in front of the carotid canal, and from the cartilage of the Euſtachian tube, it paſſes obliquely downwards and inwards, and expands in the middle of the ſoft palate. The circumflexus palati and ſuperior conſtrictor of the pharynx cover it externally, and the membrane of the pharynx on the inſide. It will draw the ſoft palate upwards, and apply it againſt the poſterior openings of the noſe.

Circumflexus palati (ſpheno-ſalpingo-ſtaphylinus; periſtaphylinus externus).—This muſcle is flattened and elongated in its figure, and lies along the pterygoid proceſs of the ſphenoid bone. It ariſes from the cartilage of the Euſtachian tube, and from a ſuperficial foſſa of the internal pterygoid plate, to which it is attached as far as the commencement of the hook-like proceſs. It then forms an aponeuroſis, which turns round the hook, being furniſhed with a burſa mucoſa; turns horizontally inwards, and expands in the middle of the palate, uniting with the muſcle of the oppoſite ſide. It is ſituated between the external pterygoid muſcle and the internal pterygoid plate, and ſuperior conſtrictor of the pharynx.

Its action will be the ſame as if it had ariſen from the pterygoid hamulus. It will draw down the velum from the noſe, and will expand it laterally.

Azygus uvulæ (palato-ſtaphylinus; ſtaphylinus; epiſtaphylinus).—It is a ſmall muſcle, ſometimes double, of an elongated form, ariſing from the pointed projection at the back edge of the os palati, and running along the middle of the velum and uvula, in which latter it terminates. It is covered on its poſterior ſurface by the membrane of the palate, and

in

in front by the expanded inſertion of the levator palati. It elevates the uvula, and ſhortens it; when we look into the throat of a living perſon, its action may be ſeen in the motions of the uvula.

Palato-pharyngeus (pharyngo-palatinus; pharyngo-ſtaphylinus).—The membranous folds continued from the ſoft palate to the tongue and pharynx contain muſcular fibres, and the poſterior ones are deſcribed under the above names. It has a broad origin in the ſubſtance of the palate from the aponeurotic expanſion ariſing from the union of the tendons of the circumflexi; paſſes firſt outwards, and then turns in an arched courſe downwards and backwards, conſiſting of a thin ſtratum of muſcular fibres. Here it follows the courſe of the pharyngo-palatine fold, the membrane of which covers it towards the pharynx. It expands into the ſide of the bag, and has its fibres mixed with the middle conſtrictor and ſtylopharyngeus, and ſlightly connected to the thyroid cartilage. In the palate it is ſituated in front of the levator palati; and below, between the membrane of the pharyngo-palatine fold, and the conſtrictores pharyngis. As both its inſertions are moveable, it may influence them both by its contraction. The ſuperior muſt be conſidered as the moſt capable of motion; it will therefore depreſs the ſoft palate, carry it away from the noſe, and bring it againſt the root of the tongue. It may, at the ſame time, contribute to elevate and dilate the pharynx. If the larynx were held in its depreſſed ſtate, it would act merely on the palate, and would bring that part in contact with the tongue; as, on the contrary, if the palate were fixed by its elevating powers, it would draw up the pharynx.

Palato-gloſſus (gloſſo-palatinus; gloſſo ſtaphylinus; conſtrictor iſthmi faucium).—This is the muſcle ſituated in the anterior or gloſſo-palatine fold of membrane, and it poſſeſſes an arched form like the preceding one. It deſcends from the palate along the anterior part and ſide of the iſthmus faucium, conſiſting of a few but eaſily diſcernible fibres, covered only by the thin membrane. It is attached to the root of the tongue. The effect of its action is very ſimilar to that of the former, the approximation of the palate to the root of the tongue.

The *tonſils* are glandular bodies occupying the ſpace left between the gloſſo-palatine, and pharyngo-palatine folds of membrane, extending above to the point at which theſe folds are united, and below to the baſe of the tongue. The palato-gloſſus muſcle lies in front of the gland, and the palato-pharyngeus behind. The two muſcles juſt mentioned preſs the tonſils between them in the act of deglutition, and ſqueeze out the ſecreted fluid from their excretory ducts. When they are inflamed, as in the various affections of theſe parts denominated ſore throat, &c. this preſſure gives riſe to the difficulty and pain experienced at that time in the act of ſwallowing. The form of the tonſil, which is ſubject to much variety, approaches moſt nearly to the oval figure, with the long axis placed perpendicularly; and the ſize is tolerably well expreſſed by the common compariſon to an almond, from which the name of *amygdalæ* has been given to theſe glands. They are often divided into lobes more or leſs diſtinct from each other. Their colour is rather grey, and their texture ſoft. The convex portion of the glands, which projects between the two folds of membrane, has ſeveral openings on its ſurface, leading into ſmall cells hollowed out in the ſubſtance of the tonſil, and lined by continuations of the membrane of the mouth. The mucus ſecreted by the veſſels of the part is depoſited in theſe cells by the excretory tubes, from which it may be preſſed out in the dead ſubject. This fluid, which is tranſparent in the healthy ſtate, becomes white and opaque in certain inflammatory affections, and then lodging in the ſuperficial cells, gives the deceptive appearance of a ſmall ulcer or ſlough in the part.

Smaller glandular maſſes of a ſimilar ſtructure and office exiſt, as we have already mentioned, in conſiderable numbers, in the ſubſtance of the velum palati and uvula. The back of the tongue is furniſhed likewiſe with ſeveral ſmall roundiſh flattened prominences, which give it an irregular and tuberculated appearance in this ſituation; there are alſo mucous glands, called *linguales;* and they diſcharge their fluids by an opening which is conſpicuous in the centre of each tubercle. The uſe of this mucous apparatus, exiſting in ſuch abundance in every part of the iſthmus or contracted aperture, which forms the communication between the mouth and pharynx, ſeems very obvious; that of furniſhing a lubricating fluid, to facilitate the paſſage of the food, particularly when it is of a dry nature.

The *tongue* conſtitutes the organ of taſte; but it is by no means confined to that office; we conſider it here as forming a part of the mouth, and as concurring by its motions in the proceſſes of maſtication and deglutition. It is alſo moſt immediately and eſſentially concerned in the production of articulated ſounds. Beſides the offices now enumerated, it performs a moſt important part in the earlier periods of our exiſtence, as an indiſpenſible agent in the act of ſuction; as the means therefore by which we derive our firſt nouriſhment.

Two parts are to be conſidered in treating of this organ: the bone ſituated under it, and affording it a firm ſupport, as well as a point of origin for the various muſcles which move it; and the ſoft muſcular body forming the tongue properly ſo called.

The *os hyoides*, or *linguale*, is ſituated between the baſe of the tongue and the larynx: the former part is cloſely connected with it above, and the latter is no leſs firmly attached below. It receives the inſertions of the muſcles of both theſe organs, and therefore is a part of the firſt importance in the ſubject of the preſent article.

It has received the name of hyoides from its reſemblance to the Greek *υ*, to which indeed it may be very well compared. It is placed in the neck, with its convexity forwards, and the two extremities backwards; and is divided into a baſis, which is the middle part, and two cornua, which form the ſides. Theſe are joined together by ſynchondroſes. The *baſis*, which is the thickeſt portion, is rather flattened in its form, and preſents an oblique ſurface to the front, marked with a more or leſs regular crucial projection, and giving attachment to the following muſcles in a ſeries from before backwards; *viz.* digaſtrici, ſtylo-hyoidei, mylo-hyoidei, genio-hyoidei, and hyagloſſi. Behind it is rather concave, and gives attachment to a membranous ligament tying it to the thyroid cartilage. The ſuperior margin has the hyogloſſus fixed to it, and the inferior receives the inſertions of the ſterno-hyoidei, omo-hyoidei, and thyro-hyoidei. It terminates at each end by a ſmooth ſurface, united to a correſponding one of the cornu, by means of cartilage; and the two parts are ſeldom anchyloſed together. The two *cornua* are much longer and thinner than the baſe, and are alſo flattened in their form. They are broader before than behind, and ſlightly bent inwards towards each other. The hyo-gloſſus and middle conſtrictor of the pharynx are inſerted into them above; the thyro-hyoideal membrane and a part of the thyro-hyoideus below. Internally they are covered by the membrane of the pharynx. The anterior and broadeſt extremities of the cornua are ſurmounted by two ſmall bits of bone, named the *cornicula* of the os hyoides. Their ſize and figure are very much like thoſe of a grain of wheat, and their poſition is inclined; one extremity pointing

downwards and forwards, the other upwards and backwards. By the former of theſe it is united to the ſynchondroſis, which connects the baſis and cornu of the os hyoides, but is moveable in its ſituation. Some fibres of the hyogloſſus are fixed to it; and its upper extremity receives the inſertion of the ſtylo-hyoideal ligament. The poſterior extremity of the cornu of the os hyoides terminates in a ſomewhat rounded tubercle, to which the hyo-thyroideal ligament is fixed. The baſis of this bone contains much of the cancellous texture; but that is leſs abundant in the cornua. Its oſſification commences by five points; one for the baſis, one for each of the cornua, and one for each corniculum. Theſe bony pieces are ſeparated at firſt by much cartilage, which is gradually oſſified, except at the points of junction, where a lamina of cartilage remains through life.

Independently of the numerous muſcles which fix the os hyoides in its place, it is attached by various ligamentous connexions. Below, the thyro-hyoideal membrane and ligaments tye it to the larynx in ſuch a way that this part follows all its motions. Thus being interpoſed between the larynx and tongue, it is a common centre neceſſary to the motions of both thoſe parts. Properly ſpeaking, it has no functions of its own; its motions are not relative to itſelf, but are deſigned merely to produce motion of the tongue or larynx. It is only connected to the tongue by means of muſcular fibres; but it is fixed to the baſis cranii by a ligament which we proceed to deſcribe.

The *ſtylo hyoideal ligament* ariſes from the ſtyloid proceſs of the temporal bone, deſcends obliquely forwards and inwards, and is fixed to the leſſer cornua of the os hyoides. It is of different thickneſs in different individuals; and often contains ſmall granulated portions of cartilage or bone. Indeed it is ſometimes converted into bone in almoſt its whole extent, and it appears then as a continuation of the ſtyloid proceſs. It prevents the depreſſion of the larynx from proceeding beyond a certain point. That cavity cannot deſcend without carrying with it the os hyoides, which is not at all reſtrained by the tongue, ſince that alſo is moveable.

Muſcles moving the os hyoides.—The digaſtricus or biventer maxillæ, which we have already deſcribed, muſt be enumerated with theſe; ſee its deſcription in a preceding part of the article.

Tranſverſus mandibulæ (mylohyoideus).—This is a very broad and rather thin muſcle; flattened on its ſurfaces, and extending tranſverſely acroſs the ſpace left between the two ſides of the lower jaw-bone. It has a tendinous origin, from an oblique ridge of the inner ſurface of the jaw, which commences juſt under the laſt molar tooth, and then extends obliquely downwards and forwards to the ſymphyſis. Its fibres are continued to the ſame point on the oppoſite ſide in an arched direction, the muſcle being concave on its ſuperior, and convex on its inferior aſpect.

In the middle of the muſcle, in a ſtraight line from the ſymphyſis of the jaw to the baſe of the os hyoides, there is a portion of tendon, broader towards the lower part, and then growing gradually narrower. All the fibres, derived from the lateral portions of the jaw-bone on either ſide, form right angles with this middle line. It muſt be immediately obvious, from the preceding deſcription, that the fibres of the muſcle differ much in length; the poſterior ones are the longeſt, and are inſerted into the upper edge of the baſe of the os hyoides, juſt behind the digaſtricus; the ſucceeding fibres become progreſſively ſhorter and ſhorter to the anterior edge of the muſcle, where their length is very inſignificant. The external ſurface of this muſcle is in contact on either ſide with the anterior portion of the digaſtricus, with the ſubmaxillary gland and latiſſimus colli. Internally it covers the genio-hyoideus, genio-gloſſus, hyogloſſus, ſublingual gland, Whartonian duct, and nerve of the ninth pair.

It elevates the os hyoides, and at the ſame time raiſes all the parts in front of that bone, which are contained in the concavity of its fibres. Hence it muſt preſs the tongue againſt the palate, and compreſs the ſublingual glands. When the os hyoides is fixed, it may depreſs the lower jaw.

Genio-hyoideus.—This muſcle, which is placed immediately behind the middle tendinous line of the tranſverſus mandibulæ, is of a rounded form, and extends from the inferior tubercle of the inner ſurface of the chin, obliquely downwards and backwards, to the middle of the baſis of the os hyoides. It lies very cloſe to its fellow of the oppoſite ſide, to which it is connected by fine and ſhort cellular threads, ſo that on a ſuperficial inſpection they would appear to form one muſcle. It is covered on its anterior and inferior aſpect by the tranſverſus mandibulæ, and lies in contact, by its oppoſite or poſterior ſuperior edge, with the genio-gloſſus.

It elevates and carries forwards the os hyoides; and of courſe it draws up the larynx at the ſame time. It aſſiſts in protruding the tongue from the mouth. When the os hyoides is fixed by the powers that depreſs it, it will draw down the lower jaw.

Stylo-hyoideus.—This is a ſlender elongated muſcle, having a tendinous origin from the ſtyloid proceſs, deſcending obliquely forwards and inwards, rather increaſing in breadth as it deſcends, and inſerted into the baſis or the front end of the cornu of the os hyoides. It is generally, but not always, furniſhed with a ſlit, through which the tendon of the digaſtricus paſſes. It is covered externally by the digaſtric, and on the inſide has the ſame relations as that muſcle. It draws the os hyoides upwards and backwards and towards its own ſide; and therefore contributes to reſtore the tongue when it has been protruded from the mouth; both muſcles acting together, muſt elevate it nearly in a ſtraight direction. If it is employed in concert with the genio-hyoideus and tranſverſus mandibulæ, the larynx will be elevated directly, as the oppoſition of the powers tending to carry it forwards and backwards prevents it from moving in either of theſe ways.

Omo-hyoideus (coraco-hyoideus, coſto-hyoideus, omoplato-hyoideus).—It ariſes by tendon from the ſuperior coſta of the ſcapula, juſt behind the notch at the root of the coracoid proceſs, and ſometimes from the ligament ſtretched over that notch. Forming a thin, flat, and narrow muſcle, it aſcends along the neck obliquely forwards and inwards, connected, as it paſſes behind the clavicle, to the back of that bone, by an aponeuroſis. It goes between the ſterno-cleido-maſtoideus, and the veſſels of the neck, and is contracted at that part into a thin and narrow tendon. Afterwards it aſſumes again the ſame fleſhy form which it poſſeſſed before, and emerging from under the ſterno-cleido-maſtoideus, aſcends more directly in the front of the neck, and contracting in its breadth is inſerted tendinous into the lower margin of the baſis of the os hyoides. It is the longeſt and thinneſt of the muſcles of the neck. It poſſeſſes in the embryo a nearly equal breadth throughout, without any middle tendinous portion. It is covered by the latiſſimus colli, ſterno-cleido-maſtoideus, clavicle, and trapezius; and lies upon the ſcaleni, the cervical nerves, carotid artery, and internal jugular vein, ſuperior thyroideal veſſels, and hyothyroideus muſcle. The ſterno-hyoideus lies along the front edge of its upper portion. It ſometimes ariſes from the clavicle. It will draw the os hyoides obliquely backwards and downwards towards its own ſide; or directly downwards, if it

acts

acts in conjunction with the oppoſite muſcle. By depreſſing the os hyoides, and fixing it in its depreſſed ſituation, it will aſſiſt, as well as the three ſucceeding muſcles, in carrying down the lower jaw. For the os hyoides is then a fixed point, from which the muſcles extending from its upper part to the jaw may act.

Sterno-hyoideus.—This is a broad, thin, and flat muſcle, ſituated on the front of the neck, juſt under the platyſma myoides, and extending from the top of the cheſt to the front of the larynx. It has a broad tendinous origin from the outer part of the poſterior ſurface of the firſt bone of the ſternum, from the contiguous cartilage of the firſt rib, from the joint of the clavicle and ſternum, and from the clavicle itſelf. It grows rather narrower as it aſcends, covers the ſurface of the trachea, and approximates to the muſcle of the oppoſite ſide. The two together completely cover the front of the larynx, and are inſerted into the middle of the lower edge of the baſis of the os hyoides, in the ſpace left between the attachments of the two omo-hyoidei. It is covered by the platyſma myoides, and ſterno-cleido-maſtoideus; and lies upon the ſterno-thyroideus, hyo-thyroideus, crico-thyroideus, thyroid gland, and ſuperior thyroid veſſels. It draws down the os hyoides and parts connected to it, as the tongue, larynx, lower jaw, &c. It may even, through the connexions of the os hyoides, bend the head forwards.

The *ſterno-thyroideus* is a muſcle of ſimilar ſhape and ſituation to the former, behind which it lies. Its origin is by a broad tendon from the poſterior ſurface of the firſt bone of the ſternum, from which part it aſcends in front of the trachea, and thyroid gland, and is ſoon marked by a tranſverſe tendinous line. Its edge at firſt touches that of the oppoſite muſcle in front of the trachea; it grows narrower as it paſſes upwards, and at the ſame time ſeparates from the other: it terminates by a tendinous inſertion into the oblique ridge of the ala of the thyroid cartilage. Its ſurface is every where covered by the ſterno-hyoideus; and it lies upon the ſubclavian, and internal jugular veins, the carotid artery, the trachea, the thyroid gland and its veſſels, and the crico-thyroideus. It depreſſes the thyroid cartilage, and at the ſame time the whole larynx, os hyoides, and parts connected with it. It concurs therefore in producing the ſame effect with the preceding muſcles, for which reaſon we deſcribe it here, although it is not attached to the os hyoides.

The *hyo-thyroideus* is a muſcle of a flattened form, ariſing from the oblique ridge of the thyroid ala, and aſcending in a ſtraight direction to the under edge of the cornua of the os hyoides, in which it is inſerted. It is covered by the ſterno-hyoideus, and omo-hyoideus externally, and it lies on the thyroid cartilage. It will mutually approximate the os hyoides and larynx; elevating the latter, or depreſſing the former, according as the fixed and moveable points may be changed. It is obvious that the muſcles, which we have juſt deſcribed, muſt be regarded in reference to the effects which they produce on parts connected to the os hyoides. The aſcent and deſcent of that bone cannot take place without correſponding motions of the larynx, and theſe are one of the means by which the tone of the voice is altered in ſpeaking or ſinging. Again, the pharynx is ſo intimately connected with the larynx, that it follows every motion of the latter; and its aſcent and deſcent in the neck, in the proceſs of deglutition, are effected through the action of the hyoideal muſcles. We ſee that the os linguale is a very moveable part; that its connexions in the neck leave it a free power of motion, and that it poſſeſſes numerous muſcles, capable of moving it in every direction.

The *tongue* occupies the lower part of the mouth; is bounded in front and at the ſides by the teeth and alveolar portions of the two jaws, behind by the epiglottis, above by the palate, and below by the os hyoides and its muſcles. Its bulk and form are ſubject to much variety, as it admits of elongation and retraction by the action of its various muſcles. It is ſmaller in ſize, and looſe towards the front; here it terminates by a rounded end, rather flattened on its upper and lower aſpects, and named the apex. At the back part it becomes broader, thicker, and more convex, and is cloſely attached below to the ſurrounding parts: this is called the baſis or root of the tongue. The ſuperior ſurface, which is perfectly looſe and unconnected in its ſituation, preſents a ſlight and general convexity, divided however by a ſuperficial groove running along its middle from before backwards, into two equal halves. Theſe are loſt towards the ſides in the two edges of the tongue, which correſpond with the interval of the two rows of teeth, and like the ſuperior ſurface are free from all kinds of attachment. The lateral portions of the organ, which are in contact with the inner ſurface of the lateral teeth, and the inner alveolar plate of the lower jaw, are flattened in their form, and are unconnected in their ſituation. The inferior ſurface of the tongue cannot be very clearly defined, as we cannot exactly point out the boundaries between the tongue itſelf and its muſcles. It is connected below, throughout at leaſt two thirds of its under ſurface, in the ſpace left between the two lateral diviſions of the lower jawbone, with ſeveral muſcles, ariſing from the jaw, ſtyloid proceſs and os hyoides, and continued into the ſubſtance of the organ, which they have the power of moving in every direction, in the cavity of the mouth. It is the intermixture of theſe muſcles with the lingual nerves and veſſels, and with a large maſs of a very peculiar muſcular fibre, called the lingualis muſcle, that forms the ſubſtance of the tongue. Towards the front of the organ the inferior ſurface is looſe and unconnected, except towards its middle, where it is tied by the frænum to the lower jaw at the poſterior ſurface of its ſymphyſis. The back edge of the tongue is connected to the epiglottis by three folds of membrane.

The membrane of the mouth, after covering the inner alveolar plate of the lower jaw, is produced over the projecting portion of the ſublingual gland, and then arrives at the inferior ſurface and ſides of the tongue; from which it is continued to the upper convex part of the organ. In the former ſituation it is ſmooth like the lining of the cheeks; but in the latter it forms a moſt rough ſurface, preſenting innumerable prominences named papillæ, and conſidered to be the immediate organs of the ſenſe of taſte; for a deſcription of which, ſee TONGUE.

Muſcles of the Tongue.—The *ſtyloglooſſus* is a ſlender elongated muſcle, having a very thin tendinous origin from the ſtyloid proceſs; it deſcends growing gradually broader, and becomes connected to the poſterior and lateral part of the tongue, along the ſide of which it runs as far as the very apex of the organ, mixed with the fibres of the hyo-gloſſus. The parts in contact with it are the digaſtricus, ſubmaxillary gland, and nerve of the ninth pair externally; the ſuperior conſtrictor of the pharynx and the lingualis internally.

Hyo-gloſſus, (baſio-gloſſus, cerato-gloſſus, and chondro-gloſſus of Albinus).—This is a broad and thin muſcle, ariſing extenſively from the os hyoides, to the baſis, cornu, and corniculum of which it is attached, aſcending in a ſtraight direction, and terminating in the ſide of the tongue. The parts in contact with it are, externally, the digaſtricus, ſtylo-hyoideus, mylo-hyoideus, nerve of the ninth pair. and ſublingual gland; internally, the lingual artery, gloſſopharyngeal nerve, and genio-gloſſus muſcle.

Genio-

Genio-gloſſus.—This is a very large, ſtrong, and broad muſcle, flattened in its front, and paſſing from the poſterior ſurface of the chin to the ſubſtance of the tongue. It has a ſmall but ſtrong tendinous origin from the higheſt of the eminences placed behind the anterior part of the lower jaw-bone. From this point its fibres extend in a radiated form; the lower ones paſs obliquely downwards and backwards, and are inſerted into the baſis of the os hyoides; and the others are continued in various directions towards the ſuperior ſurface of the tongue, according as they paſs towards the baſis, the middle, or the apex of the organ. Its fibres are moſt intimately blended with thoſe of the lingualis, as well as with the hyo gloſſus. With the external ſurface of this muſcle the following parts are in contact, *viz.* ſublingual gland, hyo-gloſſus and ſtylo-gloſſus. The oppoſite muſcle is connected by a fatty ſubſtance to its inner ſurface; and the genio-hyoideus lies along its lower and front edge.

The *lingualis* is uſually deſcribed as a ſmall elongated faſciculus of fibres placed below and at the ſide of the tongue, between the hyo-gloſſus and ſtylo-gloſſus externally, and the genio-gloſſus on the inſide, and running from the baſis to the apex of the organ. This, however, is only a ſmall part of the fibres of the tongue, the whole ſtructure of which is muſcular. It is very difficult to follow the courſe of the fibres lying under the ſuperior mucous ſurface; ſeveral are tranſverſe, ſome oblique, and others longitudinal. Their union with each other, and with thoſe of the genio, hyo, and ſtylo-gloſſi above deſcribed, conſtitutes an inextricable mixture, and all the fibres not belonging to either of thoſe muſcles muſt be ſet down to the lingualis. It is this union of muſcular fibre, together with more or leſs of a ſoft fatty matter, covered by the mucous membrane of the mouth, that conſtitutes the tongue.

Motions of the Tongue.—Theſe may be conſidered in two points of view: 1ſt, as far as they are produced by the fibres of the tongue itſelf, which form the lingualis; and 2d, thoſe which ariſe from the action of the exterior muſcles. In the firſt claſs we may enumerate 1ſt, a retraction of the tongue in the mouth, by the action of the longitudinal fibres of the lingualis; 2dly, an elongation, ſhort of the paſſage of the apex between the teeth, from the relaxation of thoſe fibres; 3dly, a curvature in the tranſverſe direction, bringing the point againſt the ſurface of the cheek, by means of the lateral longitudinal fibres; 4thly, a curvature of the apex by the inferior fibres, ſo as to bring it towards the frænum; or by the ſuperior ones, ſo as to expoſe the under ſurface of the tongue when the mouth is opened, to bring the point againſt the palate, and even to direct it towards the iſthmus faucium. It has been ſuppoſed, that the apex may be carried backwards in this direction, ſo as to produce ſuffocation. It is rather difficult to conceive this, even ſuppoſing a very peculiar natural conformation to obtain, as a remarkable looſeneſs of the frænum. But it is altogether out of the queſtion to admit it as a circumſtance generally practicable, and capable of being produced at pleaſure. The motions now deſcribed take place chiefly towards the front of the tongue, which being entirely unattached, has a great power of motion.

The following motions take place in the tongue from the action of the external muſcles. It is carried forwards, ſo that the apex paſſes between the teeth and the anterior looſe portion is protruded from the mouth, by the inferior fibres of the genio-gloſſi: the os hyoides accompanies the tongue in this motion to ſome extent, being ſlightly elevated and carried forwards. The anterior fibres of the genio-gloſſus, and the ſtylo-gloſſus reſtore the tongue to its former poſition. The depreſſion of the tongue, conſidered as affecting the whole organ, is effected by the whole of the genio-gloſſi, with the hyo-gloſſi. The elevation of the tongue, as far as the apex is concerned, is chiefly effected, as we have already ſtated, by the lingualis: the baſis is drawn upwards by the ſtylo-gloſſus. The whole organ together will be raiſed in the mouth, and preſſed againſt the palate by the tranſverſus mandibulæ. By the varied and combined actions of the muſcles, which are ſituated towards the ſides and middle of the organ, it may be rendered concave or convex in its ſuperior ſurface. It is not however to theſe ſimple motions that the tongue is confined: theſe may be modified and combined in a variety of ways which it would be difficult to deſcribe with preciſion, and which we ſhall beſt underſtand by adverting to the functions of the part as an organ of maſtication and articulation.

Maſtication.—By the parts now deſcribed the food is taken into the mouth, and retained there for the purpoſe of maſtication. There is ſome muſcular exertion at its entrance into the mouth: the lips are ſeparated, and ſlightly everted, exerting ſometimes a kind of prehenſile power, the lower jaw gently carried downwards. Liquids are taken in by the united agencies of the lips and tongue, which are obſerved to exert themſelves in two ways. The firſt method is that of ſuction, and is almoſt peculiar to the child. The nipple of the mother is embraced by the lips, which contract cloſely round it from the action of the orbicularis. The tongue formed into a longitudinal channel, by the action of the genio-gloſſi, is applied in front to the nipple, receives the fluid which comes from that part, and tranſmits it to the pharynx. When the lips and tongue are thus placed, the enlargement of the cheſt forms a vacuum in the mouth, and the preſſure of the external air on the ſurface of the breaſt forces out the milk. We can alſo drink by immerſing the lips in a fluid; and the mechaniſm is the ſame, in this inſtance, as in the preceding. This is the way in which the horſe drinks. The other method is by applying the lips to a veſſel containing the fluid, in which caſe alſo the tongue forms a channel. Here the fluid paſſes into the mouth chiefly by its own weight, as we in a manner pour it in from the containing veſſel. There is a third poſſible method of taking liquids; but it is very ſeldom employed; *viz.* by opening the mouth widely, throwing back the head, and pouring them into the throat. The food, whether ſolid or fluid, is retained in the mouth by cloſing the aperture, and applying the lips and cheeks againſt the teeth. It is propelled into the back part of the mouth by means of the lips or cheeks preſſing on it; and is moved about into every part of each diviſion of the cavity by the wonderfully quick and varied motions of the tongue, which by the elevation of its ſides is formed into a ſort of cup for that purpoſe. Or its point is paſſed between the teeth to clear the food from the corners and ſides of the cavity. At the ſame time the teeth are either brought together perpendicularly, ſo as to divide the food by the act of biting; or the inferior molares, by the lateral motions of the lower jaw, grind the alimentary ſubſtance againſt the ſuperior ones, which remain immoveable. The different portions are collected, and repeatedly ſubjected to this action by the motions of the tongue and cheeks; and when ſufficiently reduced, it is placed in a maſs on the ſuperior ſurface of the tongue, previouſly to ſwallowing.

This mechanical trituration is of the greateſt importance in preparing the food for the action of the digeſtive organs. For there is no force applied to the aliment in the ſtomach, or inteſtines, that can be at all conſidered as equivalent to the effect of maſtication. It is well-known that even the ſkin of a grape is not broken in its paſſage through the whole alimentary canal. Imperfect maſtication muſt

therefore much injure digeſtion; and hence old perſons digeſt badly, unleſs they cut their food minutely ſo as to reſemble the effect of chewing. "I can eaſily believe," ſays a great phyſiologiſt, "that a much ſmaller quantity of food would afford a ſufficient proportion of nouriſhment, if it were more completely chewed. Hence nature has attached a great pleaſure and enjoyment to the performance of this proceſs: and I have found the drieſt bread become ſweet and grateful to the palate, when long and thoroughly chewed." Haller Elem. Phyſ. t. 6. p. 40.

Salivary Glands.—The proceſs of maſtication, if it were performed on the food alone, would reduce it to a dry, or at leaſt a very tenacious maſs. that could not be moved about in the mouth for the purpoſe of complete trituration, without clogging the teeth very much, and adhering very unpleaſantly to the ſurface of the parts; and that could not certainly be ſwallowed without extreme difficulty. Theſe ſources of inconvenience are obviated by the ſalivary and other glandular apparatus placed in the neighbourhood of the mouth, and furniſhing large quantities of fluid for the purpoſe of moiſtening the food to the requiſite degree. The utility of the liquor, poured into the mouth from theſe glands, may be eſtimated from the inconvenience experienced when it is too ſmall in quantity. When we are eating very dry food, as mealy potatoes, they abſorb the ſaliva very rapidly, and require ſo much dilution, that the fluid is not ſupplied in ſufficient abundance: a difficulty is then experienced in chewing; and the morſel, which has not been duly moiſtened, often ſtops in the fauces, producing a ſenſe of ſuffocation, and paſſing down to the ſtomach very ſlowly.

The proper ſalivary glands are three in number; and they reſemble each other in their general ſtructure, although differing in ſituation, form, &c.

The ſalivary glands are ſymmetrical; that is, they are exactly alike on the right and left ſides of the body. They are all ſituated in the neighbourhood of very moveable parts, and are conſequently ſubjected by their ſituation, to compreſſion from the motions of ſuch parts. The preſſure which they thus experience from the ſurrounding bones and muſcles contributes to evacuate the contents of their excretory tubes, and to excite a farther ſecretion. As the parts, by which the glands are compreſſed, are the organs employed in maſtication, the ſecreted fluid is prepared in large quantity and poured into the mouth at the particular period when its preſence in that cavity is eſpecially neceſſary. They receive their blood veſſels in numerous ramifications, but theſe are generally produced from a large arterial trunk; and ſeveral branches of nerves from the brain are diſtributed in them. They are of a reddiſh grey colour, and tolerably firm texture. They are made up of ſeveral very diſtinct lobes, united by a cellular texture; theſe are formed by the conglomeration of many ſmaller lobules, in which we can again diſcern numerous diviſions into ſtill ſmaller particles. A thin layer of cellular ſubſtance, continuous with that which unites the different lobes, covers the ſurface of the gland; and this is again incloſed in a diſtinct and tolerably denſe capſule, connected by cellular texture of a looſe kind to the ſurrounding parts. Each of the minute particles, of which the gland conſiſts, furniſhes an excretory tube; and thoſe of the neighbouring lobuli unite together, forming larger and larger trunks, which open ultimately into the mouth, and poſſeſs an internal lining continuous with the mucous membrane of that cavity.

The Parotid Gland.—This largeſt of the ſalivary glands derives its name from being ſituated near the ear. On removing the integuments and adipous membrane from the ſide of the face, a large and flattened glandular maſs, of an irregularly oval figure, is diſcovered lying between the maſſeter muſcle and external ear before and behind, and the zygoma and angle of the jaw above and below. The gland however is much more conſiderable in its bulk than this ſuperficial view would indicate: for its ſubſtance extends conſiderably in an internal direction, in the deep hollow behind the ramus of the lower jaw. There is no diſtinction between theſe two parts, although we deſcribe them ſeparately.

The external broad portion of the gland extends more or leſs towards the face. Its outer ſurface is ſlightly convex, and partly covered by the latiſſimus colli, partly by the integuments. It covers a conſiderable portion of the maſſeter, from which it is ſeparated by the chief ramifications of the facial nerve: above it extends to the under edge of the zygoma, and lies on the joint of the lower jaw, in ſome inſtances; below it is not continued further than the ramus of the jaw, and behind it lies againſt the cartilage of the ear. The front edge is thin and irregular, and the parotid duct uſually comes off from it about a finger's breadth below the zygoma. A ſmall appendix of the gland generally accompanies the duct juſt where it emerges. The more internal portion of the gland, which is buried behind the ramus of the lower jaw, is bounded above by the joint of the jaw; in front by the inner ſurface of the ramus, and the edge of the pterygoideus internus; behind by the meatus auditorius, maſtoid proceſs and ſuperior extremity of the ſterno-cleido-maſtoideus, internally by the ſtyloid proceſs and its muſcles, the internal jugular vein and internal carotid artery. The external carotid artery paſſes through the ſubſtance of the gland, towards its poſterior part; and divides in its ſubſtance into the three branches by which it terminates; *viz.* the ſuperficial temporal, the tranſverſalis faciei, and the internal maxillary. Hence thoſe veſſels ſeem to emerge from the gland. The facial nerve paſſes alſo through the parotid, and divides in its courſe into thoſe numerous branches which form the pes anſerinus. The nutrient arteries and the nerves of this gland are derived from the trunks of both kinds which traverſe its ſubſtance. Its weight, as given by Wharton, is four drams and a half.

The *Parotid* or *Stenonian Duct*, coming out of the gland in the ſituation already deſcribed, paſſes in an horizontal direction upon the tendon of the maſſeter, and turns inwards at the front edge of that muſcle. Penetrating the fat of the cheek it goes through a diviſion in the fibres of the buccinator and opens in the mouth by a very ſmall round orifice oppoſite to the firſt molar tooth of the upper jaw. It is accompanied by ſeveral vaſcular and nervous ramifications; and ſituated ſuperficially while it is croſſing the maſſeter. In front of that muſcle it is ſurrounded by much adipous ſubſtance, and partly covered by the zygomaticus major. Its coats are very thick, and compoſed of a white, denſe, and firm ſubſtance: the calibre of the veſſel is of courſe ſmall in compariſon with its bulk. After leaving the parotid gland, it receives the excretory duct of that acceſſory portion, which is placed above it.

Sub-maxillary Gland.—This is of a roundiſh ſhape, much ſmaller than the parotid, and weighing about four drams and a half. It conſiſts of larger lobes than that gland, and is uſually ſurrounded by ſeveral lymphatic glands. It occupies the ſpace left between the inner ſurface of the ſide of the jaw, the mylo-hyoideus, and the digaſtricus. Behind it is continued nearly to the angle of the jaw, and has been ſometimes connected with the lower end of the parotid in that ſituation: towards the front it is bounded by the anterior portion of the digaſtric and the genio-hyoideus. It is covered externally partly by the baſis of the jaw, and partly by

by the latiſſimus colli; internally it lies on the lingual nerve, the ſtylogloſſus, hyogloſſus, and facial artery. A portion of this gland, continued behind the back edge of the mylo-hyoideus, joins the ſublingual, ſo that theſe two are compoſed of one continuous ſubſtance.

The arteries of the ſub-maxillary gland are derived from the facial, which is imbedded in the gland, and the lingual. The nerves are from the lingual branch of the inferior maxillary.

The excretory tube of this gland is generally called the *Whartonian Duct*. It is of large ſize, and thin in its coats. It comes off from the gland near the appendix above-mentioned, accompanies it behind the mylo-hyoideus, then goes along the inner ſurface of the ſublingual gland to perforate the membrane of the mouth juſt at the ſide of the frænum of the tongue. The aperture is much ſmaller than the diameter of the duct, and it is formed in a projecting and extenſile papilla of the membrane. It is placed, in the firſt part of its courſe, between the mylo-hyoideus and hyogloſſus: and afterwards between the ſublingual gland and genio-gloſſus. It is accompanied by the lingual branch of the inferior maxillary nerve.

The *ſub-lingual*, or ſmalleſt of the three ſalivary glands, is flattened in its figure, and very narrow from ſide to ſide, but deep from above downwards. It lies, as the name imports, under the tongue, and has the two flat ſurfaces looking right and left. It is placed between the mylo-hyoideus, and the genio-gloſſus: the two glands are parallel, and are ſeparated by the genio-gloſſi muſcles. The mylo-hyoideus covers its outer flat ſurface, and ſeparates it from the ſub-maxillary gland: the inner is in contact with the genio-gloſſus. The front edge touches the ſymphyſis of the jaw, while the poſterior reaches to the hyo-gloſſus. The ſuperior margin forms a projection in the mouth, covered only by the mucous membrane, and extending from the frænum of the tongue backwards, between the under ſurface of that organ, and the ſide of the lower jaw. The arteries come from the lingual, and the nerves from the lingual branch of the inferior maxillary. Haller has given us a minute account of the excretory ducts of this gland in the 6th volume of his great work, ſect. 2. § 7. When the ſub-maxillary and ſub-lingual glands are not connected by the appendix which we have deſcribed, and even ſometimes when they are, there is a duct ſimilar to that of Wharton, accompanying it, and opening cloſe to it. More frequently the Whartonian duct receives a large branch from the ſub-lingual gland, juſt before it opens near the frænum; and often one or two more ſub-lingual ducts open into the Whartonian. Other ſmaller ducts penetrate the membrane of the mouth on the ſurface of that longitudinal eminence, which lies by the ſide of the tongue; and Haller has ſometimes found theſe amounting in number to twenty. Small portions of a doubtful nature are ſometimes found near the ſub-lingual, and theſe too have openings into the mouth.

The fluid ſecreted by theſe glands is a pure and limpid water, as we may aſcertain in caſes of ſalivary fiſtulæ, where it may be obſerved free from any foreign admixture. But the ſaliva, as it appears when ſpit out of the mouth, is a mucous fluid, and ſo viſcid in its nature, that it entangles air in conſiderable quantity, and acquires thereby the well-known frothy appearance of ſpittle. This mucous portion of the fluid is furniſhed by very numerous ſmall glandular maſſes diſpoſed in various ſituations of the external ſurface of the membrane of the mouth, and already noticed, in preceding parts of the preſent article, under the epithets of labial, buccal, palatine, and lingual glands, and tonſils. The fluid formed in theſe glands, deſtined to moiſten and lubricate the ſurface of the mouth, is mixed with the water of the proper ſalivary glands.

Theſe mucous glands are of a roundiſh form, ſomewhat grey colour, and firm texture. They are very numerous in the lips and palate; and have ſhort ducts penetrating the membrane, and leaving conſpicuous openings on its ſurfaces; one or two of a larger ſize are occaſionally obſerved between buccinator and maſſeter, and have been deſcribed under the name of molares.

Chemical Compoſition of the Saliva.—We have already deſcribed this fluid as being made up of two different component parts, produced by very differeut organs. Dr. Thomſon gives the following account of it in the third edition of his Syſtem of Chemiſtry, vol. v. book 5. ſect. 12. "Saliva is a limpid fluid like water, but much more viſcid: it has neither ſmell nor taſte. It has a great affinity for oxygen, which it abſorbs readily from the air. Beſides water, which conſtitutes at leaſt four-fifths of its bulk, it contains the following ingredients: mucilage, albumen, muriate of ſoda, phoſphate of ſoda, phoſphate of lime, and phoſphate of ammonia. The ſaliva ſecreted in the glands above deſcribed, muſt be conveyed into the mouth by means of a contractile power reſiding in the coats of their excretory ducts. Its ſeparation is going on conſtantly, in a greater or leſs degree, ſo as to keep the mouth moiſtened, and the ſuperfluous part is uſually ſwallowed. But it is during maſtication that theſe organs are moſt actively employed, and the ſecretion which they then afford is far greater in quantity than what they furniſh in the quieſcent ſtate of the organs. The compreſſion which the glands experience from the motions of the jaw, and from the ſurrounding muſcles, is one cauſe of this increaſed quantity. For the mere motions of the jaws will increaſe the fluid of the mouth, even when no food is contained in that cavity. Another explanation has aſſigned a ſpecies of irritation in the glands produced by the preſence of the food, and aſſiſted perhaps by the mind, as in the inſtance of the taſtes. This muſt be allowed to exert an influence, as well as the mechanical preſſure. It is known familiarly to every one, that the mere ſight or ſmell of food will excite the ſalivary glands of a hungry perſon; and hence the common phraſe of one's mouth watering. Various accidental circumſtances will alſo increaſe the ſalivary ſecretion, as any ſharp or irritating ſubſtances taken into the mouth; and the effect of mercury in the ſame way is well known. The quantity of the ſalivary ſecretion in a healthy perſon can hardly be determined with any degree of accuracy. Nuck calculated from ſome experiments that twelve ounces were furniſhed in twenty-four hours; and others have ſtated it at a pint and a half. In various inſtances of ſalivary fiſtulæ, large quantities of ſaliva have been diſcharged from one gland in a ſhort time, as five or ſix ounces during ſupper time; and it is often poured out very copiouſly in perſons affected by mercury.

Paſſage of the Food into the Pharynx.—The maſticated maſs is ſuppoſed to be placed on the dorſum of the tongue, which is extended laterally, and has its margins drawn up by the ſtylogloſſi, for the purpoſe of holding it more conveniently. The muſcles of the lips and cheeks cloſe the mouth in every direction; and the lower jaw is alſo elevated, to afford a fixed point to thoſe muſcles which draw up the os hyoides. The food cannot, therefore, eſcape in any direction. The apex of the tongue is applied againſt the palate, ſo that the whole tongue repreſents an inclined plane, facing backwards and upwards; the reſt of the organ is brought ſucceſſively in contact with the roof of the mouth from before backwards, and the food is thereby forced through the iſthmus faucium into the pharynx. Theſe motions are performed

formed by the lingualis and ſtylogloſſus. The latter muſcle, together with the ſtylohyoideus and poſterior portion of the digaſtricus, carries the whole tongue backwards, ſo that it forces the portion of food into the pharynx, and oppoſes any attempt at a return. The part which the tongue has to perform is not ſo great in the act of drinking: the power of ſuction there aids the paſſage of the fluid, which runs along a channel formed in the dorſum of the tongue; that organ is, however, carried backwards in a certain degree, to convey the liquor into the pharynx. The further progreſs of the aliment in the pharynx, and the action which it undergoes in that cavity, cannot be underſtood until the parts have been deſcribed.

The *pharynx* is a large membranous receptacle, placed at the back of the noſe, mouth, and larynx, and communicating freely with thoſe organs. Thus it ſerves as a medium for the paſſage of the atmoſpheric air to and from the lungs, in the proceſs of reſpiration; for the reception of the food, which has undergone trituration in the mouth, and for its propulſion towards the ſtomach. It is adapted to the latter purpoſe by an external covering of muſcular fibres, arranged in ſtrata ſlightly diſtinguiſhed from each other, and deſcribed under the name of conſtrictores pharyngis muſcles. This bag, which is of an elongated form, extends from the baſis of the ſkull above to the point at which the larynx terminates in the trachea below. It is bounded at the ſkull by the baſilar proceſs of the occiput, below by the œſophagus, which is a cylindrical muſcular tube continued from it to the ſtomach; in front by the cavities of the noſe, mouth, and larynx; behind by the cervical vertebræ. Its breadth at the upper part is equal to the ſpace left between the pterygoid proceſſes; it is ſomewhat enlarged towards the middle, oppoſite to the os hyoides and thyroid cartilage, the cornua of which cauſe conſpicuous riſings in the membrane of the pharynx, when the bag is laid open. It diminiſhes gradually in breadth below, ſo as to become ſomewhat funnel-ſhaped: and its moſt contracted portion forms the beginning of the œſophagus. It cannot be regarded as a complete cavity, ſince it is deficient on the anterior part. When its back ſurface is laid open by a perpendicular cut, we ſee nothing in front but the openings of the naſal and laryngeal cavities and mouth. The pharynx is therefore an imperfect bag, common in the greateſt part of its extent to the air and food; and interpoſed between the external openings, which give admiſſion to thoſe, and the reſpiratory and digeſtive organs, which are the points of their ultimate deſtination.

It is firmly attached above to the baſilar proceſs of the occiput, and the body of the ſphenoid, by a ſtrong and denſe aponeurotic ſubſtance, which is gradually loſt on the mucous membrane. It is continued below into the œſophagus, oppoſite the firſt cartilaginous rings of the trachea; and a ſudden contraction at this part, viſible externally, indicates the point of continuity between the two organs. The lateral boundaries are the parts giving origin to the conſtrictor muſcles; *viz.* the pterygoid proceſſes, cornua of the os hyoides, and the ſides of the thyroid and cricoid cartilages.

In taking an internal view of its lateral connections, we find it attached, in a ſeries from above downwards, to the following parts; *viz.* the poſterior openings of the noſe, ſoft palate, back of the mouth, root of the tongue, and larynx. On the front are ſeen the wide openings of the noſe and mouth, towards the upper part; but below the bag poſſeſſes an anterior portion, which is cloſely connected to the root of the tongue, and which lies againſt the back of the larynx.

The external ſurface of the bag is connected to the bodies of the vertebræ behind by a looſe cellular ſubſtance: and along its ſides we notice the courſe of the carotid arteries and jugular veins.

The ſides of the pharynx are compoſed of muſcular fibres externally, and of membrane on the inſide. The latter is a continuation of the general mucous membrane, which belongs to the digeſtive and reſpiratory organs. This is expanded in an uniform manner over the poſterior ſurface of the bag, and by its anterior prolongations on either ſide becomes continuous with various parts. Above it is continued at the choanæ narium with the pituitary membrane, and the lining of the Euſtachian tube: lower down it is connected with the pharyngo-palatine arches, and through them with the lining of the mouth; lower ſtill it paſſes over the front of the larynx, and covers the projection which the back of that organ makes into the front of the pharynx. At the opening of the glottis it becomes continuous with the membrane that lines the organ of the voice. At the top of the pharynx it is extended along the under ſurface of the body of the ſphenoid bone, and thus becomes continuous with the pituitary membrane at the upper margin of the choanæ narium. At the bottom it is prolonged by a circular continuation into the œſophagus. It is ſmooth on its ſurface, and poſſeſſes conſiderable vaſcularity: it contains many mucous glands, affording a ſecretion which moiſtens the part, and facilitates the paſſage of the food through its cavity.

Muſcles of the Pharynx.—Theſe are four in number, according to the arrangement of the moderns; but much more numerous in the deſcriptions of ſome older writers. It follows neceſſarily, from the preceding deſcription, that they muſt be ſituated at the back of the pharynx; and they may be moſt conveniently brought into view by removing the head at the firſt vertebra, and leaving the pharynx and larynx connected to the baſis of the ſkull. We ſhall then diſcover three broad, thin, and flattened muſcles, named *conſtrictores pharyngis*, expanded like an uniform muſcular coat at the back and ſides of the bag; diſtinct from each other only at their origin, but intimately united on the pharynx, where they overlap each other ſucceſſively. The fibres from the right and left ſides meet together in the middle, and there is a white longitudinal line marking the junction: the reader will therefore underſtand, that each conſtrictor has the ſame attachments on both ſides of the body.

Conſtrictor pharyngis inferior (thyreo-pharyngeus and crico-pharyngeus).—This ariſes from the ſide of the cricoid cartilage, from the inferior cornu, and back of the ala of the thyroid; its fibres all proceed backwards, to expand over the lower part of the pharynx. The ſuperior portion aſcends obliquely towards the middle of the bag, where, together with thoſe of the oppoſite ſide, they terminate in a pointed form; the middle fibres are tranſverſe, and the inferior deſcend ſlightly, and ſurrounding the commencement of the œſophagus, are cloſely united to the muſcular covering of that organ. Hence its figure approaches on the whole to the lozenge. It is in contact, by its poſterior ſurface, with the muſcles on the front of the vertebræ; and entirely with the middle conſtrictor, ſtylo-pharyngeus, palato-pharyngeus, and membrane of the pharynx. It is covered a little at the ſide by the thyroid gland.

Conſtrictor pharyngis medius (hyo-pharyngeus).—This muſcle is exactly of the lozenge figure. Its origin is from the cornu of the os hyoides, and its fibres purſue very different directions in their expanſion over the middle of the bag. The lower ones deſcend very obliquely, and form a pointed end, covered for a conſiderable extent by the preceding muſcle; the middle ones purſue a tranſverſe courſe, and the ſuperior aſcend to terminate by a ſharp extremity fixed above into

into the baſilar proceſs of the occiput. The external ſurface of this muſcle is covered, juſt at its origin, by the hyogloſſus: in the reſt of its extent it is covered by the inferior conſtrictor, or is in contact with the front of the vertebræ. On its anterior ſurface it is in contact with the ſuperior conſtrictor, with the ſtylo-pharyngeus, palato-pharyngeus, and membrane of the pharynx.

Conſtrictor pharyngis ſupremus (pterygo-pharyngeus, mylo-pharyngeus, and gloſſo-pharyngeus).—Its fibres are tranſverſe and parallel to each other, and cover the top of the bag. Its origins are the inferior half of the internal pterygoid plate, the attachment of the buccinator to both jaws, and the ſides of the baſe of the tongue. Some of the upper fibres aſcend a little to be fixed to the baſilar part of the occiput. Covered behind chiefly by the preceding muſcle, it is contact in front with the circumflexus palati, palato-pharyngeus, and membrane of the pharynx.

The action of theſe three muſcles conſiſts in contracting the pharynx, and propelling the food through it towards the ſtomach.

Stylo-pharyngeus.—This is a thin elongated muſcle, placed at the ſide and back part of the pharynx, ariſing from the root of the ſtyloid proceſs, deſcending downwards and inwards, and paſſing under the middle conſtrictor to expand its fibres over the bag, and unite with the ſurrounding muſcles. It has an attachment alſo to the thyroid cartilage: it elevates and expands the pharynx.

Cavity of the Pharynx.—When we have laid open the pharynx by a longitudinal inciſion extending along the whole length of its poſterior ſurface, we ſee the ſoft palate hanging down into the middle anterior portion of the cavity, and ſeparating the poſterior openings of the noſe from that of the mouth. Above the ſoft palate are two large and ſomewhat oval apertures, the poſterior openings of the noſe (choanæ narium), for a deſcription of which ſee the article Nose. Through theſe the atmoſpheric air is conſtantly paſſing into and out of the pharynx, in its progreſs to and from the lungs in the alternate proceſſes of inſpiration and expiration. Through theſe openings alſo polypous tumours deſcend from the noſe into the pharynx, and are then viſible from the throat. In the ſame way the mucous ſecretion of the noſe is drawn into the pharynx; from which it is expelled by the mouth in the act of ſpitting.

The Euſtachian tube, or canal, which conveys the external air to the cavity of the tympanum, commences from the throat juſt oppoſite to the middle meatus narium. Its broad or trumpet-ſhaped opening is placed in the point of communication between the noſe and pharynx, and is kept permanently open by the cartilaginous nature of its ſtructure. Juſt behind the aperture a conſiderable ſwelling is obſerved, cauſed by a piece of the cartilage. For a more particular account of this tube, ſee Ear.

The contracted opening of the mouth into the pharynx (*iſthmus faucium*) is placed juſt under the ſoft palate. The mode in which this communication is formed has been already deſcribed in the preſent article. The ſize of this aperture, and the ſituation of the velum palati, are ſubject to much variation at different times. The ſoft palate may be drawn down againſt the tongue, and its two ſurfaces will then be anterior and poſterior. It may be elevated ſo as to ſhut the choanæ narium, and then the ſurfaces, which before were anterior and poſterior, become exactly reverſed. In the mid ſtate between the two juſt mentioned, the velum will be parallel to the horizon, and the poſterior ſurface is then ſuperior, and the anterior is inferior. The choanæ narium are cloſed by the velum palati during the act of vomiting; when the contents of the ſtomach are thrown forcibly up the œſophagus and pharynx, and would enter the noſtrils, if they were not cloſed by the elevation of the velum. Some of the ejected matter does actually paſs in this direction, which we cannot be ſurprized at, when we conſider the violence with which it is driven into the pharynx. The ſoft palate is alſo drawn up in the ſame way, when the proceſs of reſpiration is carried on through the mouth only. Haller mentions an inſtance, in which fluids injected from one noſtril returned through the other, which can only be explained by the elevation of the ſoft palate.

The larynx projects into the lower part of the front of the pharynx. In the middle and upper part of this projection there is a large opening, named the glottis, which is the entrance of the larynx. This is ſituated juſt at the root of the tongue, ſo that all the food neceſſarily paſſes over it in the act of deglutition; yet the membrane of the larynx is ſo exquiſitely ſenſible, that it cannot bear the contact of a foreign body. When by accident any extraneous ſubſtance touches this delicately organized part, a convulſive cough is excited to expel the cauſe of irritation. A drop of pure water is ſufficient to produce this effect; and if the offending matter be not immediately diſlodged, a ſenſe of ſuffocation and the moſt diſtreſſing and painful feelings enſue. If we reflect on the fatal conſequences that are almoſt immediately attendant on the interruption of reſpiration, we ſhall conſider this acute ſenſibility of the lining of the trachea and larynx as a wiſe proviſion againſt ſuffocation; by which we receive the alarm on the moſt diſtant approach of danger. Since then all the aliment muſt paſs over the glottis, and the entrance of any particle into the cavity muſt be moſt carefully guarded againſt, we have a moveable valve, called the epiglottis, cloſely connected with the root of the tongue. For a more particular deſcription of the glottis and epiglottis, ſee the article Larynx.

Progreſs of the Food in Deglutition.—At the time that the elevation and retraction of the tongue urges the morſel of aliment into the pharynx, the velum palati is drawn up againſt the choanæ narium. Hence when the ſoft palate is either partially deſtroyed by ulceration, or ſo diſeaſed as to have its motions impaired, ſubſtances which we ſwallow get into the back opening of the noſe.

The elevation and dilatation of the pharynx are accompanied by a ſimilar motion of the larynx, which cloſes the glottis, and therefore prevents the food from entering that cavity. The powers producing that elevation are the ſtylogloſſi, ſtylo-hyoidei, ſtylo-pharyngei, mylo-hyoidei, genio-hyoidei, digaſtrici, and hyo-thyroidei. Now when the larynx is raiſed, it is rather inclined forwards, ſo that the glottis is brought under the epiglottis, which amply covers it. The cloſing of the mouth, and approximation of the jaws, which take place when we ſwallow, favour the elevation of the larynx, by affording a fixed point for the action of its muſcles. This indeed is not eſſential, as we can ſwallow (fluids in particular) with the mouth open; but the act of deglutition is then inconvenient and dangerous.

The elevation and retraction of the tongue, by which the food is thruſt into the pharynx, contribute alſo to the application of the epiglottis over the opening of the larynx. For by ſuch motion of the tongue, the valve is turned backwards and downwards, and thereby meets the aſcending larynx. Yet this is not neceſſary; for we can prove on the dead ſubject, that the mere elevation of the larynx will cloſe the glottis, while the tongue is not moved at all; and indeed, if we advert to the connexions of the genio-hyoidei and genio-gloſſi, we muſt ſuppoſe that the tongue often does not contribute to the effect in queſtion. Hence we ſhall find that deglutition is practicable with the tongue held firmly to

the palate. Some phyſiologiſts have ſtated, that the food, by its preſſure on the epiglottis, depreſſes that organ more completely, and applies it more cloſely over the opening; and this appears probable enough reſpecting the more ſolid maſſes: but if we conſider that a drop of fluid, totally inadequate to produce any effect on the epiglottis, is ſwallowed juſt as well as the heavier portions of aliment, we ſhall not aſcribe much influence to this cauſe.

It is obvious, from the preceding account, that reſpiration muſt experience a temporary interruption, while the food is paſſing over the epiglottis. Hence if a perſon imprudently laugh, or attempt to ſpeak, while he is ſwallowing, the eſcape of air from the lungs, which is neceſſary in both caſes, lifts up the epiglottis, and gives admiſſion to the food, which is then not inaptly ſtated in common language to go the wrong way. No ſooner has the food paſſed into the pharynx, than the tongue aſcends, and the larynx is reſtored to its former poſition; the glottis becomes again open for reſpiration, which had ſuffered a merely momentary interruption. We cannot conclude this part of the ſubject without making one obſervation, which will naturally ſuggeſt itſelf to the reflecting mind, on the conſideration of the parts whoſe functions we are now deſcribing. We ſee that nature has deſtined the ſame organ to the performance of two important proceſſes: that the lungs derive their ſupply of air through the pharynx, and that the ſame tube conveys our food to the ſtomach; alſo, that the courſe of the aliment is eſtabliſhed directly over the opening that admits the air. We know, at the ſame time, that ſo cloſe a connexion ſubſiſts between life and reſpiration; that the interruption of this function, even for a very ſhort time, produces inevitable death. Now we can ſee very clearly, that if the glottis were left open when we ſwallow, ſuffocation would be a probable conſequence of the firſt meal, from the entrance of the food into the trachea. Hence the cloſure of the glottis has not been entruſted to the agency of any of thoſe means, which depend on the exertions of the will, which are always irregular and uncertain, and influenced by numerous circumſtances liable to change, from alterations in the bodily or mental ſtate of individuals; but it follows as a neceſſary and mechanical conſequence from certain motions of the organs, and will take place in the dead as well as in the living ſubject. Further, the very ſame condition of parts, which produces the danger, brings with it the proviſion againſt that danger. The riſk obtains only in the act of ſwallowing; and the elevation of the larynx, which is an eſſential part of the proceſs of deglutition, cloſes the glottis, and thereby obviates the riſk.

From the connexion ſubſiſting between the larynx and pharynx, as we have already explained, the latter part is elevated together with the former. It is at the ſame time dilated by the ſtylo-pharyngei; and, as the larynx is rather carried forwards, a greater ſpace is left between it and the vertebræ for the diſtenſion of the pharynx.

The ſoft palate, which at firſt was drawn up againſt the back openings of the noſtrils, is again depreſſed, as ſoon as the food has paſſed the iſthmus; and its depreſſion aſſiſts in promoting the deſcent of the food into the pharynx. This motion is performed by the palato-gloſſus and palato-pharyngeus, which bring the velum palati in contact with the back of the tongue, and thereby cut off the return of the food into the mouth, at the ſame time that its deſcent is aſſiſted. This part of the proceſs is performed with difficulty when the tonſils are ſwelled and inflamed; and the palate is not completely depreſſed at that time. No ſooner has the food entered the pharynx than that bag contracts, and then the ſpace between the tongue and vertebræ is deſtroyed by the approximation of the poſterior part of the pharynx to the tongue. This motion ſeems to ariſe from the irritation produced by the preſence of the food; for we cannot avoid ſwallowing whatever has entered the fauces. The action of the ſuperior conſtrictor muſcle draws the upper part of the pharynx againſt the ſoft palate, and thereby prevents the food, when preſſed by the muſcular powers below, from riſing towards the noſe; while the approximation of the palate itſelf to the root of the tongue prevents it from aſcending again into that cavity. The ſucceſſive contractions of the middle and lower conſtrictors now urge the food through the pharynx into the œſophagus; the arytenoidei probably cloſing the rima glottidis while the food paſſes behind that part. The larynx is now reſtored to its natural poſition by the ſterno-hyoidei, ſterno-thyroidei, and omo-hyoidei; the epiglottis riſes by its own elaſticity; and the levator palati and azygus would bring back the palate and uvula to their uſual condition.

We ſee, therefore, that the buſineſs of deglutition requires the concurrence of numerous parts, and the co-operation of ſeveral motions, and becomes conſequently a complicated and difficult ſtudy. We can underſtand how eaſily the proceſs may be deranged and impaired by the effects of accident or diſeaſe; as by wounds or diſeaſe of the tongue, by ulcers of the palate and tonſils, or fiſſures either in the bony or ſoft palates, by deſtruction of the epiglottis, or by diſeaſe affecting its motions, &c. We obſerve, alſo, that although the paſſage from the mouth to the ſtomach is placed perpendicularly, the aliment by no means deſcends from its own weight, but is urged through the whole courſe by muſcular contraction. Hence we may ſwallow with the trunk inverted; and in ſeveral animals the food paſſes upwards to the ſtomach. Hence deglutition is deſtroyed altogether by paralytic affections of the muſcles concerned in it. The ſwallowing of fluids can no more be effected by their own weight than that of ſolids: the contact of the ſides of the pharynx and œſophagus preſents an obſtacle which a mouthful of fluid is not capable of overcoming, and which requires a contraction of the muſcles. Between the oppoſing ſides of the tube, and the contracting fibres of the organ, fluids are collected into a globular form, like the more ſolid ſpecies of food; as we may obſerve in a horſe when drinking, where the paſſage of the fluid in the manner juſt deſcribed is very obvious.

The *œſophagus* is a cylindrical muſculo-membranous tube, extending from the pharynx to the ſtomach, and deſigned to convey the food from the former to the latter of theſe organs.

It deſcends through the lower part of the neck, between the trachea and the vertebræ; being not exactly behind, but rather to the left of that tube. In enters the cheſt in company with the trachea, between the two bags of the pleura; paſſes behind the left branches, and to the right of the arch of the aorta; then, turning over the deſcending aorta, goes behind the left muſcle, and deſcends through the poſterior mediaſtinum, juſt in front of that part of the aorta which lies againſt the vertebræ of the back. At its lower part it advances ſlightly forwards from the vertebral column, paſſes through the cardiac aperture of the diaphragm, and terminates in the ſtomach.

The connexions of the œſophagus to the ſurrounding parts are formed by a looſe cellular texture; on the front it is covered, in the neck, by the trachea, by a part of the thyroid gland, the left inferior thyroid veſſels, and the ſterno-thyroideus of the ſame ſide; in the cheſt, by the end of the trachea, and left bronchus, the back of the pericardium, and baſe of the heart. It correſponds behind, in the

neck, to the column of vertebræ, where it is covered by the longus colli; in the back to the thoracic duct above, and to the whole of the deſcending aorta.

The internal jugular veins and carotid arteries are on its lateral aſpects in the neck; the recurrent nerve is alſo near it on the left: in the upper part of the cheſt, the arch of the aorta lies on its left, and lower down the two pleuræ cover its ſides. At its very termination it is connected in its whole circumference to the cardiac orifice of the diaphragm. It is ſurrounded, in the lower part of its courſe, by the plexus formed by the nerves of the eighth pair.

This canal, in its empty ſtate, collapſes, and is then flat on its anterior and poſterior aſpects: when diſtended, it is cylindrical, and may have a diameter of three quarters of an inch, or more. It is uſually rather contracted, where it paſſes the diaphragm. It is, on the whole, the narroweſt portion of the alimentary canal. It extends in length from the fifth cervical to the ninth dorſal vertebra.

It is made up of two parts, very different in their ſtructure, connected by cellular ſubſtance. The external ſurface is compoſed of a muſcular expanſion, called ſometimes tunica muſcularis œſophagi, and poſſeſſing ſuch thickneſs, that the œſophagus may be deemed the moſt muſcular part of the alimentary tube. It is made up of fibres following two oppoſite directions. The external ſtratum is the ſtrongeſt, and has a longitudinal direction; they radiate below over the ſtomach; the internal are tranſverſe, and deſcribe right angles with the former.

The internal covering of the œſophagus (*tunica interna, vaſculoſa*, or *nervea*) is a white ſmooth membrane, continued from the mucous lining of the pharynx. Its ſurface is denſe and firm. It forms numerous longitudinal folds, and conſequently admits very eaſily of dilatation. It is connected by ſuch a looſe cellular ſubſtance to the muſcular covering, and poſſeſſes ſo much leſs elaſticity, that when the tube is cut tranſverſely, the latter retracts, and leaves a portion of the membranous lining protruding from the cut edge in a flaccid form. Hence a divided œſophagus ſeems to conſiſt of two tubes placed one within the other; an external thicker, red, and fleſhy; an internal thinner, white, and membranous. Small openings are ſeen on its ſurface, which are the orifices of mucous excretory ducts, ariſing from ſmall glands ſituated between the two coverings of the œſophagus. It contains a large network of veſſels, and becomes quite red from minute injections. It is continuous above with the lining of the pharynx, and below with that of the ſtomach; from which, however, it is manifeſtly diſtinguiſhed by a diſtinct and abrupt line of ſeparation, which marks the commencement of the villous ſurface.

This tube receives the food from the lower part of the pharynx, and urges it forwards into the ſtomach by the ſucceſſive action of its tranſverſe fibres: the longitudinal fibres ſeem to have the effect of ſhortening the tube, and dilating it for the reception of the food. The diaphragm preſſes on it in its contraction, ſo as to prevent the paſſage of food, and even ſo as to impede the egreſs of air from the ſtomach.

Deglutition, *Difficulty of.* See Dysphagia.

DEGNECHAM, or Dennecham, in *Geography*, a town of Holland in Overyſſel, ſeated on the Dinckel; 10 miles N.W. of Bentheim.

DEGNEZO, a town of Tranſylvania; 10 miles N.W. of Biſtricz.

DEGNIZLU, or Denizstey, a town of Aſiatic Turkey, in the province of Natolia, near the ruins of the ancient Laodicea, deſtroyed by an earthquake, which ſwallowed up many of the inhabitants: excellent grapes grow in the environs; to the eaſt and ſouth are mountains covered with ſnow; 108 miles E.S.E. of Smyrna. N. lat. 37° 51′. E. long. 29° 14′.

DEGO, a ſmall town of France, in the department of the Tanaro, chief place of a canton, in the diſtrict of Acqui, with a population of 1627 individuals. The canton contains 3 communes, and 6619 inhabitants.

Dego is ſituated near the river Bermida, and is remarkable for a victory gained in its neighbourhood over the Auſtrians, by the French under Bonaparte, in 1796.

DEGOMBAH, a Mahometan kingdom of Africa, ſituated immediately to the eaſt of Kong, or Gonjah, (the Conche of D'Anville,) and oppoſite to the Gold coaſt. Its capital is Degomba, N. lat. 12° 50′. W. long. 0° 30′. This country has on the W. Gonjah, to the N. Kaffaba, to the E. Kambah, and to the S. between it and the Gold coaſt Tonouwah. It abounds with gold, with which it ſupplies the merchants of Fezzan; and its inhabitants are diſtinguiſhed by the cuſtom of taming the elephant, and by that of ſelling for ſlaves the priſoners they take from ſuch of the bordering nations as motives of religion or avarice prompt them to invade. Afric. Aſſoc. p. 176.

DEGRADATION, in *Geology*, is a term which Mr. Kirwan has uſed (Geol. Eſſ. 437.) for the lowering or diſintegration of mountains, in ſome theories which endeavour to account for the formation of what are called alluvial or ſecondary ſtrata. See Secondary and Flætz Strata.

Degradation, in our *Law-Books*, called diſgradation, and depoſition, the act of depriving, or ſtripping a perſon for ever of a dignity, or degree of honour; and taking away the title, badge, and privileges thereof.

The degradations of a peer, a prieſt, a knight, a gentleman, an officer, &c. are performed with divers ceremonies. That which anciently obtained in degrading a perſon from his nobility, is very curious. It was practiſed in the time of Francis I. upon captain Fangel, who had in a cowardly manner given up Fontarabia, whereof he was governor.

On this occaſion, twenty or thirty cavaliers, without blemiſh or reproach, were aſſembled; before whom the gentleman was accuſed of treaſon, and breach of faith, by a king at arms. Two ſcaffolds were erected; the one for the judges, heralds, and purſuivants; and the other for the guilty cavalier, who was armed at all points, and his ſhield placed on a ſtake before him, reverſed with the point upwards. On one ſide aſſiſted twelve prieſts, in ſurplices, who ſung the vigils of the dead. At the cloſe of each pſalm they made a pauſe, during which the officers of arms ſtripped the condemned of ſome piece of his armour, beginning with the helmet, and proceeding thus, till he was quite diſarmed; which done, they broke his ſhield in three pieces with a hammer. Then the king at arms emptied a baſon of hot water on the criminal's head; and the judges, putting on mourning habits, went to the church. This done, the degraded was drawn from off the ſcaffold, with a rope tied under his arm-pits, laid on a bier, and covered with mortuary cloths; the prieſt ſinging ſome of the prayers for the dead, and then he was delivered to the civil judge, and the executioner of juſtice.

For a more domeſtic inſtance: ſir Andrew Harcla, earl of Carliſle, being attainted and convicted of treaſon, 18 Edw. II. *coram rege;* after judgment was pronounced on him, his ſword was broken over his head, and his ſpurs hewn off his heels; ſir Anthony Lucy, the judge, ſaying to him, "Andrew, now thou art no knight, but a knave." By ſtat. 13 Car. II. William lord Monſon, ſir Henry Mildmay, and others, were degraded from all titles of honour, dignities, and pre-eminences, and prohibited to bear, or uſe, the title

of lord, knight, eſquire, or gentleman, or any coat of arms, for ever afterwards.

It has been maintained that the king may degrade a peer; but it appears from later authorities, that he cannot be degraded but by act of parliament.

As to eccleſiaſtics, we have an inſtance of degradation before condemnation to death, in the eighth century, at Conſtantinople. It is in the perſon of the patriarch Conſtantine, whom Conſtantine Copronymus cauſed to be executed. He was made to aſcend the ambo; and the patriarch Nicetas ſent ſome of his biſhops to ſtrip him of the pallium, and anathematized him: then they made him go out of the church backwards.

But we have a much later inſtance in our own hiſtory: when Cranmer, archbiſhop of Canterbury, was degraded, by order of queen Mary, they dreſſed him in epiſcopal robes, made only of canvas, put the mitre on his head, and the paſtoral ſtaff in his hand; and in this attire ſhewed him to the people. Which done they ſtripped him again piece by piece.

At preſent they do not ſtand ſo much on the ceremony of degradation, in order to the putting of a prieſt to death; by reaſon of the delays and difficulties that it would occaſion. Pope Boniface pronounced, that ſix biſhops were required to degrade a prieſt; but the difficulty of aſſembling ſo many biſhops, rendered the puniſhment frequently impracticable.

With us, a prieſt, after having been delivered to his ordinary, if he cannot purge himſelf of the crime laid at his door, has his gown, and other robes, ſtripped over his ears by the common hangman; by which he is declared diveſted of his orders.

It is decided, however, that degradation does not efface the prieſtly character.

Degradation only ſeems to differ from depoſition in a few ignominious ceremonies; which cuſtom has added thereto. Accordingly in the buſineſs of Arnoul, archbiſhop of Rheims, ſentenced in the council of Orleans, in 991, it was deliberated, what form they ſhould follow in the depoſition; whether that of the canons, that is, ſimple depoſition; or that of cuſtom, *viz.* degradation. And it was declared, that he ſhould ſurrender the ring, paſtoral ſtaff, and pallium; but that his robes ſhould not be torn off.

In effect, the canons preſcribe no more than a mere reading of the ſentence. It is the reſt, therefore, added thereto by cuſtom, *viz.* the ſtripping off the ornaments, and the tearing the pontifical veſtments, that properly conſtitutes degradation.

Degradation, in *Painting*, expreſſes the leſſening and rendering dim and confuſed the appearance of diſtant objects in a landſcape, ſo that they ſhall appear there, as they would do to an eye placed at that diſtance from them. See Perspective.

DEGRADED, in *Heraldry*. A croſs degraded, is a croſs marked, or divided into ſteps at each end, diminiſhing as they aſcend towards the middle, or centre; by the French called *perronnée*. See Cross.

DEGREE, in *Algebra*, denotes the higheſt power of the unknown quantity in an equation, *viz.* the equation is ſaid to be ſimple or of the firſt degree, when it contains only the unknown quantity in its ſimpleſt ſtate; it is ſaid to be of the ſecond degree, when the ſquare of the unknown quantity is the higheſt power of that quantity contained in it; when that higheſt power is the cube of the unknown quantity, the equation is ſaid to be of the third order, and ſo forth.

Degrees, in *General*, are parts of a quantity, which is arbitrarily divided into a certain number of thoſe parts. Geometrical extenſion is in itſelf deſtitute of diviſions; the augmentation, and the decreaſe of natural powers, or forces, are (as far as we can perceive) progreſſive and uninterrupted accumulations, or diminutions of ſuch powers, wherein no natural ſteps or diviſions can be diſcerned. Thus the ſcale of heat riſes progreſſively; the ſcale of moiſture in the air, which is indicated by the hygrometer, varies uninterruptedly from the loweſt to the higheſt ſtate of ſaturation; and ſo forth. Yet, notwithſtanding the cloſe continuation of thoſe progreſſions, we have degrees of a circle, degrees of heat, degrees of moiſture, &c. Theſe degrees then only denote ſmall accumulations of thoſe powers, or certain aliquot parts of a given extenſion, which have been agreed upon by various perſons, and have been adopted for the purpoſe of underſtanding each other; or for expreſſing, without circumlocution, certain quantities of thoſe powers, or certain parts of a given circular extent.

The weight of bodies, the intenſity of light, the quantity of rectilineal geometrical extenſion, &c. are, by common conſent, likewiſe divided into parts; but thoſe parts are not always called degrees. Thus the weights of bodies are denoted by pounds, ounces, grains, &c.; rectilineal extenſion is expreſſed by miles, feet, inches, and ſo on. In geometry and in trigonometry, the appellation of degrees has been applied to angular magnitude, which is meaſured by the portion of the circumference of a circle, whoſe centre coincides with the vertex of the angle, and part of whoſe circumference is contained between the ſides or legs of the ſame angle. The magnitude or quantity of angles is reckoned in degrees; becauſe the curvature of the circle being uniform in all its parts, equal angles at the centre are ſubtended by equal arcs, and by ſimilar arcs in peripheries of different diameters. This denomination of degrees is alſo applied to denote the intenſity of heat, the quantity of aerial moiſture, and occaſionally, or leſs frequently, to ſome other natural powers.

The circumference of a circle, whatever the ſize of it may be, is ſuppoſed to be divided into 360 equal parts, called *degrees*; hence, inſtead of ſaying that a certain angle comprehends the tenth part of the circumference of a circle, we call it *an angle of* 36 *degrees*; 36 being exactly the tenth part of 360. Alſo an angle, which comprehends the 360th part of the circumference of a circle, is called an angle of one degree, and ſo of the reſt. But as the angle might not coincide with any of the degrees, therefore each degree was ſuppoſed to be divided into 60 equal parts, called *minutes*; alſo each minute was ſuppoſed to be divided into 60 equal parts, called *ſeconds*; each ſecond into 60 equal parts, called *thirds*, and ſo on. Then if an angle does not coincide with any of the degrees, it may coincide with one of the minutes, or of the ſeconds, &c.; it may, for inſtance, be equal to 11 degrees, 15 minutes, 3 ſeconds, and 45 thirds. For the ſake of brevity, inſtead of the words, the number of degrees is marked by a little ° ſet over the figure, a little on the right hand ſide of it; the number of minutes is marked with a little comma in the ſame place, the number of ſeconds with two ſuch commas, the third with three, &c. Therefore the proper or cuſtomary mode of writing the above-mentioned angle is thus, $11^\circ\ 15'\ 3''\ 45'''$. But ſince the inſtruments made for the purpoſe of meaſuring angles are not calculated to ſhew diviſions ſmaller than ſeconds, therefore the preſent more uſual way of expreſſing angles, is by writing degrees, minutes, ſeconds, and decimals of a ſecond, as, for inſtance, $82^\circ\ 13'\ 42''.347$..

It may be naturally inquired how the circle came to be divided into 360 degrees, in preference to any other number of parts? but in anſwer to this we can only offer a conjecture,

jecture, that the Egyptians, to whom this diviſion is attributed, choſe the number 360 on account of its admitting many diviſors; and perhaps alſo on account of its nearly equalling the number of days in the year, in which the ſun performs its annual revolution in the zodiac. But notwithſtanding the long eſtabliſhed uſe of this diviſion, there have not been wanting perſons, who at various times have endeavoured to recommend and to introduce a decimal or a centeſimal diviſion, inſtead of the above-mentioned one. Stevinus, Oughtred, Wallis, Briggs, Gellibrand, Newton, and lately Hutton, beſides ſeveral others, have been of this opinion. Stevinus aſſerts, that this diviſion of the circle obtained in the wiſe age, "in ſæculo ſapiente," (Stev. Coſmog. l. i. def. 6.) Hutton propoſed to divide the quadrant into equal decimal parts of the radius; by which means the degrees or diviſions of the arc would be the real lengths of the arcs in parts of the radius. See his paper in the Phil. Tranſ. for 1783. Tables of ſines, chords, &c. have even been calculated and publiſhed upon thoſe plans; and lately, in France, the decimal diviſion of the circle was actually adopted; but it appears that this new mode is attended with very little advantage in practical calculation, at the ſame time that it proves very difficult in the practice of dividing inſtruments, and liable to occaſion perplexity and confuſion in the compariſon of the new ſtatements with thoſe which fill all the innumerable and well-eſtabliſhed aſtronomical, trigonometrical, and other books. See DIVISION *of Inſtruments*.

The inſtruments generally uſed for the purpoſe of meaſuring or of laying off degrees, minutes, &c. in aſtronomy, navigation, ſurveying, and other branches of mixed mathematics, are quadrants, circles, ſextants, ſectors, theodolites, micrometers, protractors, and others. See the nature and the uſe of thoſe inſtruments under the articles of their various names.

The denomination of degrees has likewiſe been applied to a variety of other inſtruments; but principally to thermometers and hygrometers. Their meaning in thoſe inſtruments is various. In the thermometer and the hygrometer, the degrees are only parts of the diſtance run through between two fixed points. Thus in the thermometer the length of tube through which the rarefied mercury runs between the point of melting ice, and that of boiling water, is divided into a number of equal parts, which are called the degrees of the thermometer; and the ſame kind of diviſions, or of degrees, is carried on below and above the ſaid fixed points. But that very ſame length of tube, which lies between the above-mentioned two fixed points, is divided differently by different philoſophers. In Fahrenheit's thermometer, it is divided into 180 degrees; in Reaumur's, it is divided into 80 degrees; in Deliſle's, it is divided into 150 degrees; in the centigrade thermometer, it is divided into 100 degrees, &c. Hence, in order to know what part of the ſcale of heat a degree, or a given number of degrees, means, we muſt firſt know whether the thermometer is divided according to Fahrenheit, or to Reaumur, or other perſon. See THERMOMETER.

The degrees of the thermometer are marked with a little ° above and towards the right-hand ſide of the figure or figures, as 43°, 12°, &c.; but they are not ſubdivided into minutes and ſeconds. Their parts are only expreſſed by means of vulgar or decimal fractions; thus 14 degrees and three quarters of a degree, are expreſſed by $14^{\circ}\frac{3}{4}$, or by $14^{\circ}.75$.

The authors who originally propoſed and adopted the above-mentioned various diviſions of the thermometer, were undoubtedly induced to adopt their peculiar modes by various conſiderations, which at preſent are imperfectly known; nor indeed do they deſerve any particular inquiry. It is, however, curious to obſerve, that Reaumur's degrees are thouſandths of the bulk of his diluted alcohol, with which he filled his thermometers; Deliſle's degrees are thouſandths of the bulk of the mercury, neglecting the expanſion of the glaſs; and Fahrenheit's degrees are nearly thouſandths parts of the bulk of the mercury, without the laſt-mentioned inaccuracy.

It has been ſaid above, that the degrees of the thermometer are equal parts of the ſpace run through by the mercury between the points of melting ice and boiling water. This, however, is only the caſe with the mercurial thermometer, in which the degrees indicate nearly equal increments of heat; but in the ſpirit-thermometer, when properly conſtructed, the degrees are not equal, becauſe, with equal increments of heat, the bulk of ſpirit of wine increaſes unequally; hence the ſpirit-thermometer is divided with unequal degrees; but ſo as to anſwer to the equal degrees of the mercurial thermometer, *viz.* ſo as to indicate nearly equal increments of heat. See EXPANSION and THERMOMETER.

In the beſt hygrometers, the degrees are equal parts of the expanſion of the hygrometrical ſubſtance between the points of extreme dryneſs, and complete moiſture; and that ſpace is divided into 100 equal parts or degrees, which are likewiſe marked with a little ° over the figure. But in a great variety of common hygrometers, the degrees are merely arbitrary diviſions, the meaning of which cannot properly be underſtood; as moſt of thoſe hygrometers have no fixed points, and of courſe they cannot be compared with one another.

A ſimilar uſe of the word degrees muſt be underſtood with reſpect to other graduated inſtruments, which need not be particularly ſpecified.

The denominations of minutes and ſeconds, beſides their denoting the parts of a degree of a circle, are likewiſe uſed to denote the parts of an hour in the menſuration of time; an hour being divided into 60 minutes, and a minute into 60 ſeconds. But, when uſed for the menſuration of time, the minutes are more commonly (though not always) marked with a little ^{m}, and the ſeconds with a little ^{s}, inſtead of the comma or commas. Thus $13^{\circ}\ 41'\ 12''$ means 13 degrees, 41 minutes, and 12 ſeconds of a circle; and $13^{h}\ 41^{m}\ 12^{s}$, means 13 hours, 41 minutes, and 12 ſeconds of time.

It is alſo uſual to ſay, that ſuch a ſtar is elevated ſo many degrees above the horizon, meaſured in a vertical circle, or declines ſo many degrees from the equator; and that ſuch a town is ſituated in ſo many degrees of latitude and longitude; and, moreover, that a ſign of the zodiac includes 30 degrees.

DEGREE, in *Aſtronomy* and *Geography*. All circles being ſuppoſed to be divided into degrees, as explained above; we ſay degree of latitude, of longitude, of right aſcenſion and declination, to expreſs a 360th part of the circle on which thoſe quantities are meaſured. See LATITUDE, LONGITUDE, &c. &c.

If the earth were a ſphere, all the degrees on the ſame circle would be equal; but, on the ſuppoſition of its being a ſpheroid, or any irregular figure, we do not define a degree to be exactly the 360th part of the whole of a given circle, but ſuch a part of it as correſponds with a degree in the heavens. The terreſtrial degrees, therefore, are unequal, and vary according to the nature of the curve to which they belong. Thus, the degrees of the meridian are parts of an ellipſe; and the degree perpendicular to the meridian will be part of a curve of double curvature; for

for the prime vertical in the heavens is ſuppoſed to be formed by a circle paſſing through the zenith of the ſpectator at right angles to the meridian. The line paſſing through all the points on the ſurface of the earth, that have their zeniths in this circle, is the perpendicular to the meridian, and is on the ſpheroid a curve of double curvature, except at the equator and the poles. At the equator it is the equator itſelf, and at the poles a meridian. For let A (*Plate* VI. *Aſtronomy*, *fig.* 47.) be a place ſituated between the pole and the equator, and A B B be the perpendicular to the meridian P A. The firſt element, or ſide of this line, will be in the plane A M B, determined by the vertical A M, and the ſide A B. For the ſame reaſon, the ſecond ſide B B′ will be in the plane B M B′, B N B′ being the vertical of the point B. From the nature of the ſpheroid, C M is always greater than C N; the vertical B N will be, therefore, inclined to the plane A M B, as will likewiſe the line B B′, which repreſents the prolongation of the line A B, bent in the direction of a ſtraight line parallel to B N. It can be equally proved, that B B″ ſeparates from the plane B N B′; conſequently, the four points A, B′, B″, B‴, are not in the ſame plane. Thus, finally, the perpendicular to the meridian is, in general, a curve of double curvature.

The degrees of latitude which, on a ſphere, would be equal, increaſe as they approach the pole on an oblate ſpheroid. The degrees of longitude are always equal on the ſame circle, both on the ſphere and regular ſpheroid.

On the ſphere they decreaſe as they recede from the equator, in the proportion of radius to the coſine of the latitude. On a ſpheroid, the degree of longitude is equal to a degree of a great circle perpendicular to the meridian, multiplied by the coſine of the latitude, as will be demonſtrated hereafter.

Meaſurement of a Degree.

It is by the meaſurement of different degrees on the ſurface of the earth, that we acquire our knowledge of its magnitude and figure; and as this problem has engaged the attention of mathematicians and aſtronomers in all ages, and is, beſides, one of the moſt important and intereſting in practical geometry, we ſhall enter into all the details relating to it at conſiderable length, and endeavour to trace its hiſtory from the earlieſt times to the preſent day.

There is every reaſon to believe that the ſolution of this problem was attempted at a very remote period of antiquity. And if it be allowed to ſupply the ſilence of hiſtory by conjecture, we may preſume that an attentive conſideration of the ſame phenomena that firſt indicated the ſpherical figure of the earth, ſuggeſted the idea that its whole magnitude might be aſcertained by the meaſure of a ſmall portion of its ſurface.

The firſt attempts to accompliſh this purpoſe were, doubtleſs, very rude and inaccurate; but it is evident, that a great and unexpected ſtep was made in the progreſs of human knowledge, the moment a juſt conception of this theory was obtained.

It is in vain that we now inquire at what period this diſcovery was made; we know with what myſterious ſecrecy the learned in thoſe early ages veiled their knowledge from the vulgar, either becauſe their opinions were too much at variance with the prejudices of the ignorant to have been communicated with ſafety, or, what is equally probable, the temporal advantages they derived from this reſerve were too conſiderable to be hazarded by an indiſcreet diſcloſure of their ſecrets, which would have reduced them nearer to the level of ordinary men.

To what accuracy the ancients really did attain in their endeavours to meaſure the magnitude of the earth, is a diſputed queſtion among the learned to this day.

Bailly, indulging in his favourite theory, ſtrives to perſuade us that traditionary meaſures muſt have been tranſmitted from the antediluvian world, which were thoſe of the aſtronomers of the early ages; and that theſe being very preciſe aliquot parts of a degree, were neceſſarily founded on an accurate meaſure of a portion of the earth's circumference. It is not our deſign to enter into this controverſy, or to treat with diſreſpect the opinions of a man whoſe talents were ſo deſervedly celebrated, and whoſe fate is ſo juſtly deplored. We ſhall content ourſelves with obſerving, that we can meet with nothing on this ſubject ſufficiently authentic to merit the attention of the reader, previouſly to the eſtabliſhment of the Alexandrian ſchool, about 300 years before the Chriſtian era.

The firſt meaſurement we find upon record, to which tradition has affixed the name of an individual, is that of Eratoſthenes of Alexandria, the ſucceſſor of Ariſtarchus. We regret that a more detailed account of this celebrated operation has not been tranſmitted to us.

It appears that Eratoſthenes determined the difference of latitude between Syene and Alexandria in Egypt to be 7° 12′; and this diſtance having been previouſly meaſured (as is ſaid) by the royal ſurveyors of Alexandria to be 5000 ſtadia, he concluded the circumference of the earth to be 250,000 ſtadia.

The length of this ſtadium is not exactly known. Some of the learned men who accompanied the French expedition into Egypt, have, by means of an ancient nilometer found in the ruins of Elephantis, eſtabliſhed with great preciſion the relation which the ancient Egyptian cubit bears to our modern meaſures; and they have endeavoured, with great ingenuity, to deduce the exact dimenſion of the ſtadium from the ſame data. If they are correct, we ſhould infer, that the degree meaſured by Eratoſthenes did not differ from the truth above one thouſandth part of the whole. We believe that every perſon, who has any practical knowledge of the difficulties attending an operation of this kind, will require very little argument to be convinced, that if ſuch a remarkable coincidence does really exiſt, it muſt be attributed to the effect of accident alone. For the latitude of Syene was only determined by obſerving, that a deep well received the vertical rays of the ſun on the day of the ſummer ſolſtice, without any perceptible ſhadow. The latitude of Alexandria might, perhaps, be determined ſomewhat more correctly. But the amplitude of the whole arc could ſcarcely be eſtimated to within 10′ of the truth; ſuch an error alone would produce a correſponding one of above 1000 toiſes in the value of the degree.

Of the trigonometrical meaſurement we know ſtill leſs. It would certainly be a very favourable ſuppoſition, to admit it true to the one-hundredth part of the whole; and to this, likewiſe, muſt be added the uncertainty in determining the direction of one place, relative to the meridian of the other. All theſe circumſtances conſidered, we muſt allow, that if the reſult did not differ from the truth more than one-fiftieth of the whole, it muſt have been by a very fortunate compenſation of errors.

Poſſidonius is the next aſtronomer whoſe name we find connected with this ſubject. He was a native of Apamea, in Syria, from whence he removed to Rome. He is ſaid to have determined an arc of the meridian, and to have eſtimated the circumference of the earth at 240,000 ſtadia. The ſilence of cotemporary writers relative to the details

neceſſary

neceſſary to an operation of this kind, renders it probable that the determination of Poſſidonius was only founded on an inveſtigation of the labours of others. His data were neceſſarily extremely vague, ſuch as the diſtances of different places computed by navigators, and their latitudes probably determined in a moſt inaccurate manner; ſo that the obſervation we made on the degree of Eratoſthenes applies, with equal propriety, to that of Poſſidonius: and really theſe meaſures would ſcarcely deſerve the notice of men of ſcience, but for the importance which ſome learned men have attached to them.

Ptolemy, who lived near 300 years after Eratoſthenes, conſiders the circumference of the earth as equal to 180,000 ſtadia. It has been conjectured, that this meaſure is identical with that of Poſſidonius of 240,000, a different ſtadium being referred to by each of them. This opinion is the more admiſſible, as we know that the Egyptian cubit has been divided at different times into 32 and 24 digits. It is poſſible, therefore, that the ſtadium ſuppoſed to be derived from the cubit, might, likewiſe, be liable to the ſame proportional variation.

During a long dark period of nearly 1400 years, but one ſolitary inſtance occurs of any attempt either to verify or improve theſe ancient meaſures. About the year 814 the caliph Almamon, the ſon of Haroun al Raſchid, aſſembled his aſtronomers on the plains of Meſopotamia, and ordered one party to travel north and the other ſouth, till they had changed the ſituation of their zenith one degree from the place of their departure. We neither know how they determined their latitude, nor how they meaſured their diſtance.

The degree reſulting from this meaſurement is reported to have been eſtimated at 56 miles and a half; but ſo great is the uncertainty relative to the ſtandard employed, that this meaſurement, like many others, may be conſidered as loſt to poſterity.

In the year 1528, Fernel undertook to meaſure the length of a degree, and aſcertained the diſtance between Paris and Amiens by counting the revolutions of the wheel of a carriage. He eſtimated the degree at about 68,096 geometric paces. Here is, likewiſe, ſome uncertainty as to the value of theſe geometric paces.

Picard eſtimates Fernel's degree at 57,070 toiſes, Riccioli at 62,706.

Thus, the labour of this meaſurement is likewiſe loſt, from the circumſtance of ſeveral meaſures exiſting in the ſame country of one denomination. We have not much to regret, perhaps, in this particular caſe, but had the operation been ever ſo exact, we ſhould equally have been deprived of the advantage of it. Nevertheleſs, M. de la Lande thinks Fernel's meaſure pretty well known, and conſiders it as accurate, which muſt have been accidental, conſidering the imperfect nature of this method. He determined the latitude of his extreme ſtations by taking the altitude of the ſun with parallactic rules ſimilar to thoſe of Ptolemy of eight feet radius.

Snellius, in the year 1617, meaſured a portion of the meridian between Alknaar and Bergenopzoom: his method was in its principle perfectly correct. He meaſured a baſe, and deduced the diſtance of two extreme ſtations by a ſeries of triangles, obſerving the latitude of each of them. He failed in computing the degree very exactly, which, in ſome meaſure, aroſe from his having taken too ſhort a baſe, only 631 toiſes; and, likewiſe, from not being provided with inſtruments ſufficiently accurate for the purpoſe.

Norwood, a native of this country, in the year 1635, meaſured the arc of the meridian, contained between London and York, with conſiderable care.

He determined the altitude of the ſun on the day of the ſolſtice, in two different years, at each place, and found the difference of latitude 2° 28′; he meaſured the diſtances by chains, ſometimes by paces, eſtimating, as well as he could, the various windings in the direction of the road, and found the degree to contain 367,196 Engliſh feet, or 57,300 toiſes. This meaſurement of Norwood ſeems entitled to more reſpect than it obtained: it had at leaſt the merit of being more exact than any that preceded it.

We ought not in this place to omit the meaſurement of Riccioli, founded on a method firſt ſuggeſted by Kepler, which conſiſts in obſerving the depreſſion of two diſtant objects below the horizon. It may be inferred, from the property of the ſphere, that the ſum of the depreſſion of two diſtant objects is equal to the arc intercepted between them. This may be eaſily underſtood by referring to *Plate* VI. *fig.* 48. A and B are two ſtations, ſufficiently elevated for either to be viſible to a ſpectator placed at the other: A *c*, B *c*, the reſpective horizons. In the trapezium A *c* B C, A and B being right angles, the angles C and *c* are together equal to two right angles. Therefore, the angle *c* A B, and *c* B A, or the ſum of the depreſſions, is equal to the angle C. Riccioli meaſured the angle A B C on the mountain of Paterno, near Bologna, formed by the perpendicular B C, and the tower of Modena. He then obſerved the angle C A B at the tower of Modena, which the perpendicular A C made with a ſignal on the tower of Paterno to be 90° 15′ 7″. The ſum of theſe two angles, 179° 41′ 20″, being taken from 180°, leaves 18′ 40″ for the angle A C B.

He then meaſured the included diſtance, and found it equal to 20,016 paces of Bologna: from theſe data the value of a degree might be calculated by a ſimple proportion. Riccioli appears to have taken a great deal of pains with this method, which, however, is very defective in practice, both from the uncertainty of the terreſtrial refractions, and likewiſe from the ſmallneſs of the included arc. And, therefore, it is not ſurpriſing that the reſult was inaccurate: he made the degree 63,000 toiſes, which is not within one-tenth of the truth.

Such was the ſtate of uncertainty, relative to this intereſting problem, till the eſtabliſhment of the academy of ſciences in France. One of the firſt operations of that learned body was the determination of the magnitude of the earth; and Picard was entruſted with the execution of the project. But, to enable the reader to underſtand the different operations that ſucceeded theſe imperfect eſſays, it may be proper to ſtate the nature of the problem a little more diſtinctly, and to give a general outline of the principle on which its ſolution is founded.

Fig. 49. Let A and B be two places nearly north and ſouth of each other. M N, a meridian paſſing through A. B *x*, a perpendicular from the ſtation B, falling on the meridian M N. The object is to determine the difference of latitude between A and *x*; to aſcertain the diſtance between them in terms of ſome known ſtandard meaſure; and then, by a ſimple proportion, to find the value of a degree. Thus, if the difference of latitude between A and *x* ſhould be found to be 40′, and its meaſured diſtance 40,000 fathoms, we ſhould ſay, 40′ : 40,000 fath. :: 60′ or 1° : 60,000 fath. = the meaſure of a degree.

For this purpoſe, the moſt uſual method is to meaſure a baſe line, as *a b*, with all imaginable care: a number of intermediate ſtations are then to be ſelected. as conveniently ſituated for the purpoſe as poſſible. Theſe conſiſt of ſuch ſteeples, towers, or other conſpicuous objects as are to be met

met with; and when theſe are wanting, ſignals erected to ſupply their place. By means of theſe ſtations, a ſeries of triangles are formed, by which A and B are connected with each other, and with the baſe line *a b*, as in *fig.* 49. The reſpective angles of theſe triangles are then accurately meaſured with a theodolite, and as the baſe line forms one ſide of one triangle, all the others may be found by a trigonometrical calculation. When the baſe line is ſituated near one extremity of the arc, it is not unuſual to meaſure a baſe of verification near the other extremity, and to compare its length by actual meaſurement with that deduced by computation by means of the intervening triangles. This is an excellent teſt of the accuracy of the trigonometrical proceſs.

The baſe being meaſured, and the ſides and angles of the triangles determined, two more operations, entirely aſtronomical, are requiſite to complete the proceſs. The difference of latitude of the extreme ſtations muſt be determined with the greateſt preciſion, and likewiſe the direction which one of the ſides of the firſt triangle makes with the meridian M N. Sufficient data are now obtained for finding the perpendicular diſtance of each ſtation from the meridian M N; as *p p'*, *q q'*, *r r'*, and B *x*; and alſo the diſtance of each perpendicular from A, as A *p'*, A *q'*, A *r'*, and A *x*. A *x* and B *x* being thus obtained, the diſtance and bearing of B may be found by the rules of plane trigonometry. The latitude of the other point *x*, which is uſed in finding the amplitude of the arc A *x*, is deduced from the obſerved latitude of B. It is true, that this can only be done rigorouſly by a ſpherical calculation, the ſmall arc B *x*, found in toiſes or feet, being converted into minutes and ſeconds of a degree. To do this, we muſt ſuppoſe known the very thing we are in ſearch of, that is, the relation the degree bears to our ſtandard meaſures. But as the arc B *x* is always taken very ſmall, compared with A *x*, no practical inconvenience is found to ariſe from this approximation.

It appears then, that the whole proceſs conſiſts of four diſtinct operations; the meaſurement of a baſe; the determination of the angles of a ſeries of triangles, ſo conſtructed, as to connect the extreme ſtations, both with the baſe and with each other; the determination of the latitudes, or, at leaſt, the difference of latitude of the extreme ſtations; and, laſtly, the relative bearing of one ſtation with the meridian of the other.

From the varied and uneven nature of the ſurface of the earth, ſeveral complicated conſiderations ariſe in practice, that have been entirely omitted in the preceding deſcription. For, as theſe ſtations are taken in an extended range of country, it muſt neceſſarily happen that they will be very unequally elevated or depreſſed above one common level. So that, if we ſuppoſe triangles to be formed by lines joining their ſummits, theſe will produce a moſt irregular figure; no two triangles, probably, lying in the ſame plane. Before the requiſite calculations can be made, theſe ſtations muſt all be reduced to the level of one uniform ſpherical ſurface (which ſurface is uſually ſuppoſed to be the level of the ſea). *Fig.* 50. is intended to illuſtrate the nature of theſe reductions. A, B, C, D, E, are the elevated ſignals; *a*, *b*, *c*, *d*, *e*, their places reduced for computation. To have an accurate idea of this reduction, we may ſuppoſe lines drawn from the centre of the globe to the vertices of the ſtations: the points formed by the interſection of theſe lines with the imaginary ſpherical ſurface, every where level with the ſea, are thoſe which are to be uſed in the ſubſequent calculation.

The triangles formed by theſe points may either be conſidered as plane or ſpherical: in one caſe, their ſides are chords paſſing through the earth; in the other, curved lines drawn over its ſurface.

We may here likewiſe explain the principle of another method, which hereafter we ſhall have occaſion to deſcribe more at length; this is the determination of the value of an arc oblique or perpendicular to the meridian, by means of azimuthal angles, by which the direction of the meridian with the adjoining ſtation is aſcertained.

Let P (*fig.* 51.) be the pole of the earth, A any place whoſe latitude is known, B a ſtation viſible from A; an obſerver at A determines the azimuthal angle P A B, the angle P B A is likewiſe obſerved at the ſtation B, and the diſtance between A and B meaſured trigonometrically; then in the triangle P A B, P A is known, being equal to the co-latitude of the place; and the two angles being known, the ſide A B may be found; and thus the value of a degree, or an oblique circle, obtained. If A *p* be drawn perpendicular to A P, then in the triangle A B *p* the two angles *p* A B and *p* B A are given, as likewiſe the ſide A B, as found above. By theſe we may find the value of A *p*, which is a portion of the great circle perpendicular to the meridian. And this arc A *p* may be always known in linear meaſure, by the rules of plane trigonometry.

It is evident that on a ſphere all theſe degrees ſhould be equal.

We may now return to the hiſtorical part of our ſubject, and reſume the narrative of the operations of Picard, who, as was before ſtated, was entruſted with the meaſurement of a degree between Paris and Amiens. (A. D. 1699.)

In *Plate* VI. *fig.* 52, may be ſeen the general diſpoſition of Picard's triangles. The angles were meaſured with a quadrant of three feet radius, furniſhed with two teleſcopes, the one fixed, the other moveable.

He began his operation by meaſuring the diſtance between Villejuive and Juveſy, which places being nearly joined by an even paved road, were thought moſt eligible for his purpoſe: he found this diſtance to be 5863 toiſes.

Beginning at Juveſy, he meaſured the angle which a mill at Villejuive, that terminated his baſe, made with the ſteeple at Brie. The angle made by the two teleſcopes was 95° 4′ 55″. He then carried the inſtrument to Villejuive, and there directing one teleſcope of the quadrant to a ſignal at Juveſy (which formed the other extremity of his baſe), and the other to the ſteeple at Brie, he found the angle ſubtended by theſe two objects to be 54° 4′ 35″. With theſe two angles, and the included ſide, it was eaſy to deduce the diſtance from Villejuive to Brie, = 11,012.8 toiſes. This meaſure was verified by taking the inſtrument to Brie, and obſerving the third angle of the triangle, which appeared by obſervation to be the ſame as it ſhould have been by computation from the other two. The diſtance thus found by the firſt triangle ſerved as a baſe to the next, whoſe vertex was the celebrated tower of Montlhery. The angles at Villejuive and Brie being 77° 25′ 50″, and 47.34 reſpectively, the diſtance from Brie to Montlhery was deduced 13,121 toiſes. This diſtance was found, by a more careful meaſurement in the year 1756, to be 13,108. The third and fourth triangles were both formed on this baſe; one was limited on the north by the tower of Montjay, the other on the ſouth by the flag ſtaff of Malvoiſine. Theſe gave the diſtances from Montlhery to Malvoiſine 8870½ toiſes, and Montlhery from Montjay, 21,658. The fifth triangle, founded on this baſe, terminated at Mareuil. From theſe triangles the diſtance from Malvoiſine to Mareuil was calculated to be 31,897.

Having determined this great triangle by means of the ſubordinate ones, he was deſirous of verifying it by direct meaſure-

measurement, and for this purpose procured large fires to be lighted, of three feet diameter. When viewed through the telescope of the quadrant, these are said to have resembled in appearance stars of the third magnitude: they seemed however to subtend an angle of 8″ instead of 3″ or 4″, which they should have done by calculation; from which it was inferred that luminous bodies sometimes appear larger than they really are. By proceeding in this manner, he found, by means of 13 triangles, the distance from Malvoisine to Sourden, near Amiens, to be 68,430½ toises, and with a zenith sector of 10 feet radius, he found the difference of latitude to be 1° 11′ 57″.

By observing the azimuth of the pole-star at its greatest digression at Mareuil, he determined the direction which the sides of his triangles made with the meridian; and drawing perpendiculars from the stations to the meridian, he was enabled to complete the intercepted portions.

From these data he concluded a degree in the latitude 49° 7′ to be 57,060 toises. This result differs very little from that deduced from later measurements; yet this great precision arose, in some degree, from a compensation of errors.

In 1756 two pyramids were erected at the extremities of the base, at Villejuive and Juvesy, at the exact distance of 5786 toises, when, upon a re-examination of Picard's operation, his distances were found to be too great by one toise in a thousand, either because his measure was not identical with that subsequently used, or that his base had not been determined with sufficient precision.

The success that attended Picard's measurement, and the accuracy that trigonometrical operations were found to possess, determined the academy to extend his triangles still farther in the direction of the meridian both to the north and south.

This was partly carried into execution by Dominique Cassini, in the year 1683. He assumed as a base the distance between Montlhery and Brie, as determined by Picard, and had completed a chain of twenty principal triangles, to a station 60 leagues south of Paris, when the death of Colbert, the great patron of science, for a time interrupted these pursuits.

It was not till the year 1700 that they resumed their labours. Cassini, assisted by his son Jaques Cassini, and Maraldi his nephew, continued the series of triangles as far as the neighbourhood of Perpignan, above 6° south of the observatory of Paris.

They traced a base of verification 7246 toises, a little to the eastward of Perpignan, the length of which, by direct measurement, was found to agree very exactly with that deduced by calculation from the triangles.

The northern part of the arc from Paris to Dunkirk was not terminated till the year 1718. The astronomers employed on this occasion were Jaques Cassini, Maraldi, and De la Hire. They likewise measured a base of verification in the vicinity of Dunkirk. When the result of these operations was examined, the southern degree was found equal to 57,097 toises, and the northern 56,960. It was thus that, after a period of 30 years from its commencement, this great work was brought to a termination.

The result, as far as it related to the relative magnitude of different degrees, was certainly erroneous; but this we cannot be surprised at, when we recollect the imperfect state of astronomical instruments at that period; but by these operations the foundation for the improvement of the science of geography was laid. The advantage of combining astronomical and trigonometrical observations was distinctly perceived, and the project formed of extending these triangles over the whole superficies of the kingdom.

But the above mentioned operations began to derive an additional interest, from a question of great importance that about that time engaged the attention of the scientific world; this was the determination of the *true* figure of the earth. Hitherto we have considered the measure of a degree as the only requisite step for determining the earth's magnitude, upon the supposition of its being perfectly spherical; in which case, all the degrees of latitude being equal, it is evident that the measure of one would have afforded sufficient data for estimating the value of the whole circumference.

But the discoveries of Huygens and Newton, about this time, rendered it more than probable that the equatorial parts of the earth must at some period of its existence have yielded to the centrifugal force acting on them in consequence of the diurnal motion, in such a manner, as to have given to the globe an oblate form, such as we may conceive produced by the revolution of an ellipse about its shorter axis. If this theory be just, the degrees should increase in proportion as we recede from the equator, and approach the poles.

For we define a degree of the meridian to be that space which we must pass over (in moving directly north or south), to produce a change in the vertical line equal to that quantity. We have seen above, that the degrees measured in France indicated a contrary tendency; and we cannot wonder that those, who had bestowed so much pains in an operation which, if exactly performed, should have solved the problem at once, should be unwilling to see their labours overturned by a hypothetical calculation. Men of science were very much divided on this question; the arguments derived from theory were certainly very strong in favour of the flattened figure at the poles; on the other hand, it had so happened, that the best known measures at that time, indicated that the polar axis was the longest. Cassini proposed measuring trigonometrically a degree of longitude, or, what was still preferable, a degree of a great circle perpendicular to the meridian. This scheme was adopted and carried into effect; and it so happened, that the result likewise of this experiment rather favoured the idea that the polar axis was the longest. We know now that this operation is of a more delicate nature, and attended with greater practical difficulties, than the measurement of an arc of the meridian. But though these trigonometrical measurements were insufficient to clear up the doubt that existed relative to a difficult point in the theory of the earth; yet the addition made to geographical science was very great: for an arc perpendicular to the meridian was measured from the western coast to Strasburg; and, as we have before mentioned, these triangles being afterwards extended over the whole kingdom, gave to the geography of that country a precision unknown in any other part of the world.

The trigonometrical measurement, even at that period, was very correct; the errors were occasioned chiefly by want of accuracy in the astronomical part of the process.

Cassini de Thury, who was engaged at a subsequent period in continuing these operations, had so much confidence in his trigonometrical operations, that, having met with an astronomer in the range of his triangles who congratulated him on their accuracy, because they agreed with his observations: rather, replied Cassini, let me offer you my compliments on the correctness of your observations, since they are so fortunate as to agree with my triangles.

It was in the year 1733 that Condamine represented to the academy, that the best way of arriving at the truth, amidst such a variety of opinions, would be to procure a measure of the degree at, or very near, the equator, and he offered himself to share the difficulties and celebrity of the enterprise.
